# THE ERRATA OF COMPUTER PROGRAMMING

This report lists all corrections and changes of Volumes 1 and 3 of The Art of Computer Programming, as of January 5, 1979. This updates the previous list in report CS551, May 1976. The second edition of Volume 2 has been delayed two years due to the fact that it was completely revised and put into the TEX typesetting language; since publication of this new edition is not far off, no changes to Volume 2 are listed here.

The present report was prepared with a typesetting system that is now obsolete; please do not wince at the typography. All cahnges and corrections henceforth will be noted in TEX form on file ERRATA.TEX[ART,DEK] at SU-AI.

In spite of inflation, the rewards to error-detectors are still \$2 for "new" mistakes in the second edition, \$1 in the first edition.

Please do not endanger the author's morale by asking him about Volume 4. Thank you for your understanding.

to appear,  $\rightsquigarrow$  75-77,

**1,91** replace lines 1-3 by the following new copy 8/25/76 23

The coefficients  $B_k^{(n)}$  which appear in the last formula are called "generalized Bernoulli numbers"; Section 1.2.11.3 examines them further in the important special case  $n = 1$ . For small  $k$ , we have  $B_k^{(n)}/k! = (-1)^k \binom{n-k}{n-k} (n-k-1)!/(n-1)!$ , but when  $k \geq n$  this formula breaks down since it reduces to 0 times  $\infty$ . An analogous situation holds for the power series  $(x/\ln(1+x))^n$ , where the coefficient of  $e^k$  for  $k < n$  is  $\binom{n-k}{n-k} (n-k-1)!/(n-1)!$ .

each with a random lifetime,  $\rightsquigarrow$  each equally likely to be the next one deleted,

**1,446** new paragraph after line 6

1/16/77 64

Our assumption that each deletion applies to a random reserved block will be valid if the lifetime of a block is an exponentially-distributed random variable. On the other hand, if all blocks have roughly the same lifetime, this assumption is false; John E. Shore has pointed out that type A blocks tend to be "older" than type C blocks when allocations and deletions tend to have a somewhat first-in-first-out character, since a sequence of adjacent reserved blocks tends to be in order from youngest to oldest and since the most recently allocated block is almost never type A. This tends to produce a smaller number of available blocks, giving even better performance than the fifty-percent rule would predict. [Cf. *CACM* 20 (1977), 813-820.]

new paragraph to be inserted after line 4:

A related model of computation was proposed by A. N. Kolmogorov as early as 1952. His machine essentially operates on graphs  $G$ , having a specially designated starting vertex  $v_0$ . The action at each step depends only on the subgraph  $G'$  consisting of all vertices at distance  $\leq n$  from  $v_0$  in  $G$ , replacing  $G'$  in  $G$  by another graph  $G'' = f(G')$ , where  $G''$  includes  $v_0$  and the vertices  $v$  at distance exactly  $n$  from  $v_0$ , and possibly other vertices; the remainder of graph  $G$  is left unaltered, its components are attached to the vertices  $v$  at distance  $n$  as before. Here  $n$  is a fixed number specified in advance for any particular algorithm, but it can be arbitrarily large. A symbol from a finite alphabet is attached to each vertex, and restrictions are made so that no two vertices with the same symbol can be adjacent to a common vertex. (See A. N. Kolmogorov, *Uspekhi Mat. Nauk* 8,4 (1953), 175-176; Kolmogorov and Uspenskii, *Uspekhi Mat. Nauk* 13,4 (1958), 3-28, *Amer. Math. Soc. Translations*, series 2, 29 (1963), 217-245.) Such graph machines can easily simulate the linking automata defined above, taking one graph step per linking step; conversely, linking automata can simulate graph machines, taking at most a bounded number of steps per graph step when  $n$  and the alphabet size are fixed. The linking model is, of course, quite close to the operations available to programmers on real machines, while the graph model is not.

1,487 new answer, continued

4/19/77 77

For example, Eq. (6) holds for all complex  $k$  and  $n$ , except in certain cases when  $n$  is a negative integer; Eqs. (7), (9), (20) are never false, although they may occasionally take indeterminate forms such as  $0 \cdot \infty$  or  $\infty + \infty$ . We can even extend the binomial theorem (13) and Vandermonde's convolution (21), obtaining  $\sum_k \binom{r}{a+k} x^{a+k} = (1+x)^r$  and

$\sum_k \binom{r}{a+k} \binom{b-k}{s-k} = \binom{r+b}{s}$ , formulas which hold for all complex  $r, s, a, b$  whenever the series converge, provided that complex powers are properly defined. [See L. Ramshaw, *Inf. Proc. Letters* 6 (1977), 223-226.]

1,487 new answer

11/12/76 78

42.  $1/(r+1)B(k+1, r-k+1)$ , if this is defined according to exercise 41(b). In general it appears best to define  $\binom{r}{k} = 0$  when  $k$  is a negative integer, otherwise  $\binom{r}{k} = \lim_{s \rightarrow r} \Gamma(s+1)/\Gamma(k+1)\Gamma(s-k+1)$ , since this preserves most of the important identities.

Show that ... comparisons.  $\rightsquigarrow$  Let  $U_t(n)$  be the minimum number of comparisons needed to find the  $t$  largest of  $n$  elements, without necessarily knowing their relative order. Show that  $U_2(5) \leq 5$ .

**S.220** new exercise

12/19/76 202

**25.** [M32] (A. Schönhage, 1974.) (a) In the notation of exercise 14, prove that  $U_t(n) \geq \min(2+U_t(n-1), 2+U_{t-1}(n-1))$  for  $n \geq 3$ . *Hint:* Construct an adversary by reducing from  $n$  to  $n-1$  as soon as the current partial ordering is not composed of components  $\circ$  or  $\rightarrow$ . (b) Similarly, prove that  $U_t(n) \geq \min(2+U_t(n-1), 3+U_{t-1}(n-1), 3+U_t(n-2))$  for  $n \geq 5$ , by constructing an adversary which deals with components  $\circ$ ,  $\rightarrow$ ,  $\rightarrow$ ,  $\rightarrow$ . (c) Therefore we have  $U_t(n) \geq n + t + \min(\lfloor (n-t)/2 \rfloor, t) - 3$  for  $1 \leq t \leq n/2$ . (d) The inequalities in (a) and (b) apply also when  $V$  or  $W$  replaces  $U$ , thereby establishing the optimality of several entries in Table 1.

E. G. Mallech [*Comp. J.* 20 (1977), 137-140] has experimented with refinements of Brent's variation, and further recent work on this topic has been done by G. Gonnet and I. Munro [*Proc. ACM Symp. Theory Comp.* 9 (1977), 113-121].

**3,527** insertion of new material after line 20 12/19/76 263

Algorithm R may move some of the table entries, and this is undesirable if they are being pointed to from elsewhere. Another approach to deletions is possible by adapting some the ideas used in garbage collection (cf. Section 2.3.5): We might keep a "reference count" with each key telling how many other keys collide with it; then it is possible to convert unoccupied cells to empty status when their reference count is zero. Alternatively we might go through the entire table whenever too many deleted entries have accumulated, changing all the unoccupied positions to empty and then looking up all remaining keys, in order to see which unoccupied positions really require 'deleted' status. This procedure, which avoids relocation and works with any hash technique, was originally suggested by T. Gunji and E. Goto [to appear].

**S.606** answer 11 11/29/77 288

In general, ... elements.  $\rightsquigarrow$  The situation becomes more complicated when  $N = 64$ ; K. Sedgwick has shown how to compute the worst-case permutations, and he has proved that the maximum number of exchanges is  $1 - \lg \lg N / \lg N + O(1/\log N)$  times the number of comparisons [*SIAM J. Computing*, to appear].

**S.607** new answer 16

11/29/77 289

16. Consider the  $\binom{2n}{n}$  lattice paths from  $(0,0)$  to  $(n,n)$  as in Figs. 11 and 18, and attach weights  $f(i-j)$  if  $i \geq j$ ,  $f(j-i-1)$  if  $i < j$ , to the line from  $(i,j)$  to  $(i+1,j)$ ; here  $f(k)$  is the number of bits  $b_r \neq b_{r+1}$  in the binary expansion  $k = (\dots b_2 b_1 b_0)_2$ . The total number of exchanges on the final merge when  $N = 2n$  is

$$\sum_{0 \leq j < i < n} (2f(j)+1) \binom{2i-j}{i-j} \binom{2n-2i+j-1}{n-i-1}.$$

R. Sedgewick has simplified this sum to

$$(1/2)n \binom{2n}{n} + 2 \sum_{k \geq 1} \binom{2n}{n-k} \sum_{0 \leq j < k} f(j) \text{ and used the gamma function method to obtain}$$

the asymptotic formula  $\binom{2n}{n} \{ (1/4)n \lg n + (\lg(\Gamma(1/4)^2/2\pi) + 1/4 - (\gamma+2)/(4 \ln 2) + \delta(n))n + O(\sqrt{n \log n}) \}$ , where  $\delta(n)$  is a periodic function of  $\lg n$  with magnitude bounded by .0005; hence about 1/4 of the comparisons lead to exchanges, on the average, as  $n \rightarrow \infty$ . **S.637** new answer

12/19/76 302

25. (a) Let the vertices of the two types of components be designated  $a; b < c$ . The adversary acts as follows on nonredundant comparisons: Case 1,  $a:a$ , make an arbitrary decision. Case 2,  $x:b$ , say that  $x > b$ ; all future comparisons  $y:b$  with this particular  $b$  will result in  $y > b$ , otherwise the comparisons are decided by an adversary for  $U_t(n-1)$ , yielding  $\geq 2 \cdot U_t(n-1)$  comparisons in all. This reduction will be abbreviated "let  $b = \min; 2 \cdot U_t(n-1)$ ." Case 3,  $x:c$ , let  $c = \max; 2 \cdot U_{t-1}(n-1)$ .

(b) Let the new types of vertices be designated  $d_1, d_2 < e; f < g < h > i$ . Case 1,  $a:a$  or  $c:c$ , arbitrary decision. Case 2,  $a:c$ , say that  $a < c$ . Case 3,  $x:b$ , let  $b = \min; 2 \cdot U_t(n-1)$ . Case 4,  $x:d$ , let  $d = \min; 2 \cdot U_t(n-1)$ . Case 5,  $x:e$ , let  $e = \max; 3 \cdot U_{t-1}(n-1)$ . Case 6,  $x:f$ , let  $f = \min; 2 \cdot U_t(n-1)$ . Case 7,  $x:g$ , let  $f$  and  $g = \min; 3 \cdot U_t(n-2)$ . Case 8,  $x:h$ , let  $h = \max; 3 \cdot U_{t-1}(n-1)$ . Case 9,  $x:i$ , let  $i = \min; 2 \cdot U_t(n-1)$ .

(c) For  $t = 1$  we have  $U_1(n) = n-1$ , so the inequality holds. For  $1 < t \leq n/2-1$ , use induction and (b). For  $t = (n-1)/2$ , use induction and (a). For  $t = n/2$ ,  $U_t(n-1) = U_{t-1}(n-1)$ ; use induction and (a). Exercise 14 now yields the following lower bound for the median:  
 $V_t(2t-1) \geq 3t + t/2 - 4$ .

12/19/76 400

add p. 450 to Vaughan Pratt entry

3.765 addendum to previous change 324

11/15/78 401

John M. Pollard has discovered an elegant method for index computation in about  $O(\sqrt{p})$  operations mod  $p$ , requiring very little memory, based on the theory of random mappings. See *Math. Comp.* 32 (1978), 918-924, where he also suggests another method based on numbers  $n_j = r^j \pmod p$  that have only small prime factors.

THE TEX/METAFONT PROJECT.

WHAT HAS BEEN DONE:

Don Knuth has finished (and frozen) the implementation of TEX (the typesetting system) and is currently involved in the implementation of METAFONT (the font generator).

WHAT WE WANT TO DO:

We want to complement TEX / METAFONT with a suitable hardware environment, namely:

- \* An XGP type device that will provide hardcopy capabilities both for proofreading and for (medium quality) originals.
- \* A high resolution typesetting device for high quality originals.
- \* A high resolution CRT terminal, capable of displaying TEX output.

We also want to make the system widely available, thus it is needed to implement it in a more widespread language (PASCAL).

And finally we would like to try our hand in making TEX more interactive than what it is now. (This one is a tougher cookie.)

IF YOU ARE INTERESTED:

There are many things to be done. There are learning opportunities. There are academic goodies (units, CS293 projects, etc). And there is also monies.

FOR MORE INFO:

Send a message to LTP, or call 74425 or 74377.
