EXPENDABLE SOUND VELOCITY AND TEMPERATURE PROBE (XSVT) TO INFER SALINITY VERSUS DEPTH SEA TEST RESULTS

A quantity of 156 Expendable Sound Velocity and Temperature (XSVT) Probes were manufactured by Sippican Corporation under Contract N00014-77-C-0769 to determine the feasibility of manufacturing an expendable probe that simultaneously measures sound velocity and temperature to infer salinity versus depth. The existing technologies of the Expendable Sound Velocity (XSV) Probe and the Expendable Bathythermograph (XBT) Probe were combined to create the dual-functioning XSVT probe. A prototype AN/BQH-7 Recorder, designed to record submarine XBT (SSXBT) data, was modified to accept XSV data and was reprogrammed to simultaneously record temperature and sound velocity data on a strip chart recorder and on tape cassettes.

From September 12 - 20, 1978 Dr. M. Miyake, of the Institute of Ocean Sciences, Sidney, B.C., Canada, conducted the "Line-P Experiment" aboard the C.S.S. PARIZEAU to compare the Sippican XSVT probe and the Grundy(XCTD) probe against the Plessey Model 9050 STD with sound velocity probe, the Guildline Model 7800 CTD system, the Ramsey MKI sound velocity sensor, and hydrographic bottle casts. During the experiment Sippican launched 110 XSVT probes at twelve stations in the North

Pacific (see Figures 1 and 2). At Station SN1 and Station 7, 36 XSVT probes were deployed to provide the XSVT comparison against the Plessey Model 9050 STD with sound velocity sensor that is the subject of this report.

DATA ANALYSIS

Data from the CTD cast Number 17 made on September 17, 1978, beginning at 20:20 at Station SN1 have been compared with a series of XSVT probe launches at the same location beginning at 19:25 and ending at 22:27. XSVT probe data were sampled at 100 ms intervals during probe descents.

The equation for depth is:

$$H = 5.706t - 0.0026t^2$$

Where H is depth in meters and t is time in seconds. For every five meters of descent the above equation was used to calculate t at that depth. Since data were sampled every 100 ms, the equation:

$$\text{Sample number} = t(\text{seconds}) \times \frac{10 \text{ Samples}}{\text{Second}}$$

gives(when rounded to the nearest whole number) that sample which is closest to a given depth increment. This process allowed comparison of data at approximately 5 meter intervals as listed in the computer printouts.

R-929

For each 5 meter increment recorded sound velocity and temperature data were used in Lovett's third equation* to calculate salinity. Pressure in the equation was calculated from:

$$P = H(1.0072)$$

which produces no larger than an overall .1% depth error when compared to the cast 17 pressure data.

Thirty-six probes were launched at the SN-1 location. Twenty-seven probes provided both acceptable sound velocity and temperature data. Temperature data were disrupted after 400 meters for many of the probes due to wire leaks, but sound velocity, which is essentially immune to minor wire leak problems, continued to provide good data throughout most of the launches.

Computer plots of the data (see Appendix) show the cast 17 data for temperature, sound velocity, and salinity in red. All XSVT plots are in black and are right-shifted exactly two major chart divisions from each other. Probe identification is given directly below each plot.

Comparison of plotted CTD and XSVT temperature data shows good agreement in the mixed layer to within .08°C. Repeatability is good also. Sound velocity data are repeatable but consistently high by .2 to .3 m/sec. Detection of the thermocline occurs approximately 8 meters deeper with the XSVT probes, and is fairly consistent for all the probes. The 8-meter

*J. R. Lovett, "Merged Seawater Sound-Speed Equations," J. Acoust. Soc. Am., Vol. 63, No. 6, June 1978

offset appears continuous throughout those areas of changing temperature or sound velocity and is somewhat undiscernible after 300 meters due to the smoothness and consistency of the data. Salinity plots show low frequency oscillation around the CTD salinity profile in the order of .25 to .5HZ, with peak-to-peak amplitudes of .2 to .5 parts per thousand. The fluctuations are fairly symmetrical and center along the CTD profile within .1 to .2 parts per thousand in most cases. Their causes are due mostly to the presence of low frequency and 60-cycle interference in the DC sourced temperature data. Calculation of salinity thus produces an amplification of the inherent noise as shown on the salinity plots. Drastic salinity deviations are caused by wire leaks grossly offsetting temperature data.

Based on recent tests performed at the NATIONAL SPACE TECHNOLOGY LABS, it has been determined that a significant error in sound velocity is introduced due to a change in ambient temperature of the potted probe electronics. Carefully controlled measurements of a number of probes revealed that a 10°C drop in ambient temperature produced a positive error of approximately .2 m/sec. All the probes used in the Line-P Experiment were calibrated at approximately 25°C; thus, storage of the probes at temperatures less than 25°C would introduce an offset error and the resulting readings would be proportionately higher. It was also determined that the thermal time constant of the electronics potting was about

four minutes, although almost insignificant here since the drop time was under three minutes. Finally, another contributing factor has since been discovered causing a significant positive offset to the data independent of environmental conditions. After the transducers were calibrated the wire leads were shortened prior to final assembly into the probe body. The shortening of the leads caused a fixed offset in the carrier frequency resulting in a positive offset of .1 to .3m/sec.

Conclusively, all sound velocity data gathered in this test are expected to be high by .1 to .3 m/sec. due to a calibration problem and .2 m/sec. per 10°C drop in storage temperature from 25°C due to the temperature sensitivity of the electronics package. Thus, the accuracy of the salinity data is limited by the inaccuracies of the sound velocity data. Close analysis of the salinity plots reveals that in most cases the average salinity follows that measured by the CTD to within ± .2 parts per thousand.

A number of corrective steps have been taken since this experiment to improve the accuracy and reliability of future data. An attempt has been made to minimize 60-cycle interference in the recorder by shielding the transformer, rerouting the power wires, and installing line filters. A noise problem on the bridge circuit has been eliminated by the removal of a high frequency signal which was in close proximity to an analog-to-digital converter integrating capacitor. Also, more stringent probe calibration pro-

cedures have been incorporated, transducer lead lengths are maintained, and the electronics package is being analyzed in an attempt to minimize the effects of ambient temperature changes.

PROBLEMS

1. The sound velocity offset can be caused by a temperature ceofficient problem in the thin-film hybrid circuit and by the shortening of the transducer leads. The transducer lead length can be controlled in future probes but the hybrid circuit problem has not been resolved.

2. Noise on temperature data can be caused by recorder-induced noise, by the XSV signal, or possibly by the Guildline or Plessey STD coupling noise into the wire. Corrections have been made to the production AN/BQH-7 recorder to reduce the recorder-induced noise. Further testing is needed to determine if noise problems remain.

3. The XSVT probe wire consistently fouled with the cable of the Guildline or Plessey instruments due to poor weather and wind conditions. When the XSVT wire came into contact with the cable, the insulation of the XSVT wire was usually damaged, degrading the temperature data.

It would be misleading to determine a probe yield on this sea test. The incidence of wire leaks for the XSVT probe should equal the incidence of wire leaks for a new XBT probe. The XSV portion of the probe functioned in most cases despite wire leaks.
