## ABSTRACT

Certain weather advisory functions were delegated to the Group H-6 (LASL) Weather Section during test activities at the Nevada Proving Grounds. Techniques utilized in performing these functions are outlined, and the actual advisories, forecasts, and analyses issued are made a matter of record.

The weather advisory functions outlined herein were fulfilled by Lt Col C. A. Spohn through Upshot-Knothole 8, at which time Lt Col Spohn received transfer orders and was superseded by his assistant, Maj George J. Newgarden III.

## ACTIVITIES OF THE SPECIAL WEATHER ADVISORY SERVICE

### 1 GENERAL

The Weather Section of the Health Division of the Los Alamos Scientific Laboratory was delegated the responsibility to provide certain specialized weather advisory service for the Advisory Panel during Operation Upshot-Knothole. In addition, the Weather Section maintained close liaison with the Radiological-Safety (Rad-Safe) Group on those items which were of special interest to that organization. Generally, the same functions were performed as in Operations Buster-Jangle and Tumbler-Snapper. The specific functions are as follows:

#### 1.1 Preshot Functions

1. Preparation of fall-out forecasts and plots.
2. Forecasts of maximum bomb-cloud height.
3. Assistance to the CAA representative in determining necessary airspace closure.

Forecasts of bomb-cloud trajectory, which would normally be a function of this group, were made by the Air Weather Service forecast team at Mercury Forecast Center, under the direction of Lt Col DeWitt Morgan, chief forecaster.

#### 1.2 Postshot Functions

1. Preparation of additional fall-out plots, as required.
2. Computation of cloud heights.
3. Recommendations for changes in CAA airspace closure.
4. Analysis of cloud trajectories.

Postshot analysis of fall-out was also carried out, but, since this was frequently completed a considerable time after the shot, it is not considered an integral part of the test advisory service. However, postshot fall-out analysis charts are included in this report.

### 2 FALL-OUT FORECASTS AND PLOTS

Forecast fall-out patterns were prepared at 2100 local time on D-1 day for briefings given the Advisory Panel. These forecasts were based on the wind forecast for the target area at shot time, as prepared by the Mercury Forecast Center. (See the Appendix to Activities of the Special Weather Advisory Service, Operation Buster-Jangle Report, WT-418, for a description of the technique of preparation of fall-out forecasts.) In addition, fall-out plots were prepared based on all wind soundings made at the Control Point between 2100 local time and shot time. These preshot fall-out plots and the postshot plots were primarily for the use of the controller of the offsite monitoring section of the Rad-Safe Group in positioning his monitors.

~~RESTRICTED DATA - CONFIDENTIAL - SECURITY INFORMATION~~

~~CONFIDENTIAL~~

Since fall-out plots are based on single station winds aloft (i.e., the Control Point at Nevada Proving Grounds), it must necessarily be assumed that the wind field is constant (i.e., no space-time changes). Obviously such is seldom the case; therefore, upon completion of each test, postshot analysis of fall-out was undertaken. Since wind space-time changes are considered in these analyses, their accuracy is improved considerably. In all cases the postshot analysis fall-out charts included in this report verify very closely the facts obtained by the Rad-Safe offsite monitors.

The various fall-out forecasts, plots, and postshot analyses are shown in Figs. 1 to 48. Discussion of the patterns for each individual shot follows.

#### 2.1 Upshot-Knothole 1 (Figs. 1 to 4)

The briefing forecast indicated fall-out to the northeast. Fall-out plots prepared from the 0100 and 0430 PST wind soundings indicated that the fall-out sector was gradually shifting to the east. The postshot analysis shows that the fall-out did occur almost due east of zero point.

#### 2.2 Upshot-Knothole 2 (Figs. 5 to 8)

The briefing forecast indicated fall-out again to the northeast. Fall-out plots from 0100 and 0330 PST wind soundings indicated a minor shifting of the fall-out sector to a more northerly heading. The postshot analysis shows that the high-level fall-out occurred in the north-northeast quadrant and the low-level fall-out occurred slightly west of north.

#### 2.3 Upshot-Knothole 3 (Figs. 9 to 12)

The briefing forecast indicated fall-out to the southeast. Fall-out plots from 0100 and 0330 PST wind soundings indicated little change. The postshot analysis shows that the fall-out did occur to the southeast; however, there was a marked increase in the horizontal speed of the fall-out.

#### 2.4 Upshot-Knothole 4 (Figs. 13 to 16)

The briefing forecast indicated fall-out to the south-southeast. Fall-out plots from 0330 and 0530 PST wind soundings indicated little change. The postshot analysis shows that the fall-out did occur to the south-southeast, although the high-level fall-out was slightly more easterly than was forecast.

#### 2.5 Upshot-Knothole 5 (Figs. 17 to 20)

The briefing forecast again indicated fall-out to the south-southeast. Fall-out plots from 0100 and 0430 PST wind soundings indicated gradual shifting to the south. The postshot analysis shows that the fall-out did occur to the south-southeast; however, it was more southerly than was forecast.

#### 2.6 Upshot-Knothole 6 (Figs. 21 to 25)

The briefing forecast indicated fall-out to the east-northeast. Fall-out plots from 2330, 0200, and 0420 PST wind soundings indicated a marked shift to the southeast. The postshot analysis shows that the fall-out did occur to the southeast.

#### 2.7 Upshot-Knothole 7 (Figs. 26 to 30)

The briefing forecast indicated fall-out to the east. Fall-out plots from 0115, 0230, and 0415 PST wind soundings indicated a shift to the southeast. The postshot analysis shows that the fall-out occurred to the east-southeast.

~~RESTRICTED DATA - CONFIDENTIAL - SECURITY INFORMATION~~

~~CONFIDENTIAL~~

#### 2.8 Upshot-Knothole 8 (Figs. 31 to 34)

The briefing forecast again indicated fall-out to the east. Fall-out plots from 0430 and 0815 PDT winds indicated a slight shift to the east-northeast. The postshot analysis shows that the fall-out did occur to the east-northeast.

#### 2.9 Upshot-Knothole 9 (Figs. 35 to 38)

The briefing forecast indicated fall-out to the east. Fall-out plots from 0200 and 0500 PDT wind soundings indicated a slight shift to the northeast, especially the low-level fall-out sector. The postshot analysis shows that the fall-out did occur to the northeast, although high-level fall-out occurred almost due east.

#### 2.10 Upshot-Knothole 10 (Figs. 39 to 43)

The briefing forecast indicated fall-out to the northeast. Fall-out plots from 0200, 0400, and 0815 PDT wind soundings indicated little change. The postshot analysis shows that the fall-out did occur to the northeast but approximately 15° more northerly.

#### 2.11 Upshot-Knothole 11 (Figs. 44 to 48)

The briefing forecast indicated fall-out to the southeast. Fall-out plots from 2330 and 0130 PDT wind soundings indicated a slight shift to the east-southeast. The fall-out plot from the 0500 PDT wind sounding indicated little change in the high-level fall-out sector; however, the plot indicates inconsistency in the low-level fall-out pattern owing to light and variable low-level winds. The postshot analysis shows that high-level fall-out occurred slightly south of east, low-level fall-out occurred around point zero, and the horizontal speed of fall-out decreased markedly.

#### 2.12 Summary

The primary fall-out patterns (i.e., fall-out occurring from the cloud proper and the upper stem) do not show excessive shifts from the briefing forecasts to D day postshot analysis, generally less than 35° with a mean error of approximately 27°. The low-level fall-out patterns, however, occasionally show extreme shifts, as in Upshot-Knothole 6 and 11. It is the weak gradient type of pressure pattern at low levels which presents the meteorologist with the most difficult problem in forecasting wind direction.

### 3 CLOUD-HEIGHT FORECASTS AND DETERMINATIONS

A forecast of anticipated maximum cloud height was prepared immediately preceding the fall-out forecast and was included in the material presented at the briefing. These cloud-height forecasts were used to determine the levels from which fall-out could be expected, to determine the levels of concern for the CAA airspace closure, and to determine the levels for sampling by aircraft samplers.

#### 3.1 Forecast Techniques

The forecasts were made using regression equations derived from Ranger, Buster-Jangle, and Tumbler-Snapper data. Independent variables were bomb yield, wind speed, atmospheric lapse rate, and height of tropopause (for yields greater than 10 kt only).

#### 3.2 Determination Techniques

Beginning at 1 min after shot time and continuing at 1-min intervals up to approximately

~~RESTRICTED DATA - CONFIDENTIAL - SECURITY INFORMATION~~

~~CONFIDENTIAL~~

15 min, elevation angles to both top and base of the bomb cloud were obtained by theodolite. These were combined with the wind data closest to zero time to determine the cloud height by the following method. An initial cloud height was determined from the elevation angle. The base line was then corrected by applying the 1-min cloud drift indicated by the wind flow in the layer through which the cloud was rising. This new base-line distance and the elevation angle then yielded a second approximation. Since these 1-min corrections to the cloud height were rarely in excess of 1500 ft, the second approximation yielded as much accuracy as the method justified.

Any errors in the technique are due to the assumptions that wind data taken about 10 miles from point zero, and as much as an hour earlier or later than shot time, represented the wind layer through which the cloud passed and that all theodolite sightings are really made on the top and base of the cloud. This latter item is of less importance if the cloud is moving away from the theodolite location, but when the cloud approaches the theodolite it becomes of major importance since it is more difficult for the observers to take a correct sight. Nonetheless it is believed that these results are more accurate than cloud-height estimates made by test aircraft pilots who are basing their estimates on pressure-altimeter readings, which may be off by several thousand feet at higher elevations. During the Upshot-Knothole test series, two simultaneous theodolite readings, one from the CP and one from the old Ranger CP, were obtained from Upshot-Knothole 1 through 10. The cloud-growth curves included in this report are based on the mean values of the two theodolite readings. Since Upshot-Knothole 11 was a night shot, theodolite data are not available. However, corrected data obtained for Upshot-Knothole 11 by test aircraft are as follows: maximum height of top of cloud, 42,700 ft MSL; maximum height of base of cloud, 35,000 ft MSL.

### 3.3 Results

Figure 49 shows the forecast and computed cloud heights for Upshot-Knothole. (Heights for Upshot-Knothole 11 are based on aircraft reports.) For nine of the shots the mean forecast error was approximately  $\pm 2000$  ft. In the case of Upshot-Knothole 4, however, the cloud top was forecast 8000 ft lower than it occurred. This shot was a high-level air burst for which the cloud-top regression equation was not designed as it is when based on tower shots. The result of this high-level air burst suggests that the amount and rate of rise of the cloud are also dependent on the atmosphere pressure level at burst height. In the case of Upshot-Knothole 6 the cloud top was forecast 8000 ft higher than it occurred. Preliminary data indicate that the actual yield of the bomb was somewhat lower than anticipated and used in the regression equation. Other cloud-height forecast errors are due to inaccurate forecasts of wind speeds, atmospheric lapse rate, and tropopause height.

Figures 50 to 59 show individual cloud-growth curves as computed from theodolite and wind data. It is interesting to note the tendency of the cloud to sink after attaining maximum height.

## 4 CAA AIRSPACE CLOSURES

### 4.1 Closure Determination

On the evening prior to each shot a conference was held, immediately following the briefing, to determine the air sectors which would have to be closed to traffic during and after the shot. Participating members in the conference were representatives of the CAA, Test Director, Health Division Meteorological Section, and Rad-Safe Group. At this conference an initial closure plan was determined, based on (1) forecast cloud trajectory at various levels, (2) forecast height of cloud top and base, and (3) a dosage computation developed by T. N. White, LASL, which considered the wind shear, rate of turbulent diffusion, radioactive-decay rate, and the bomb yield.

~~RESTRICTED DATA CONFIDENTIAL SECURITY INFORMATION~~

~~CONFIDENTIAL~~

Following shot time this closure plan was amended as required when reports of tracking aircraft, later wind data, and cloud-height computations indicated that items 1 and/or 2 differed markedly from the forecast values.

It was also necessary to ensure that no dangerous contamination could occur to nonparticipating aircraft and personnel and at the same time to minimize disruption of commercial air schedules. Because of the operating techniques of CAA, the philosophy of the conference was always to plan the closure so that changes would be more likely to release airspace than to close additional airspace, since the former could be done much more rapidly and positively than the latter. Further, last-minute closure of airspace seriously disrupts commercial aircraft service. This ensured that the first requirement would be met, even if the second could not always be.

#### 4.2 Form of Closure Plan

The closure plan had to be drawn up in such a form that it could be easily administered by the CAA control center at Salt Lake City. The form which was devised as meeting this need most completely is described in the following paragraphs.

(a) *Flash Circle.* A circle, of generally a 50-mile radius, center at 37°N, 116°W, closed at all altitudes for a period of several hours which included shot time. The flash circle was to ensure that no aircraft was close enough to the blast at shot time for the pilot to suffer eye injury or temporary blindness.

(b) *Sector.* A pie-shaped wedge, the tip at 37°N, 116°W, was marked out to include those elevations and areas of normal outside traffic (i.e., outside the range) in which cloud and debris drift was anticipated while still dangerous.

(c) *Warning Circle.* A circle of sufficient size to include both the flash circle and the sector was laid out centered on some well-known town. The circle was for the convenience of CAA in alerting pilots as to the region through which flight plans needed to be cleared with the control center. It was the only part of the closure plan which was released to the general public by the CAA control center at Salt Lake City.

(d) *High-level Quadrangle (or Triangle).* The high-level quadrangle was closed to all aircraft for a considerable period (12 to 15 hr). This region was always much larger than the warning circle and covered the region through which the cloud proper was expected to drift while still hazardous. The base of this region was generally above 26,000 ft and hence was above the level of commercial traffic. Distribution of this notification was handled by the CAA control center at Salt Lake City, which notified those military airfields handling high-level traffic.

The closure plans for the Upshot-Knothole series are included as Figs. 60 to 70. Owing to complexity of corrections, all changes to a given closure plan are listed in the figure legends.

#### 5 CLOUD TRAJECTORIES

Following each shot a cloud-trajectory analysis was carried out. Appropriate levels were selected to cover the vertical extent of the cloud, within the limits as imposed by the wind data available. For the selected levels, constant-level wind charts were plotted and analyzed, by streamline analysis, at 6-hr intervals (i.e., the intervals at which synoptic wind soundings are made at the various meteorological stations nationwide). The cloud was then moved at each level as indicated by the streamlines and isotachs, assuming that the analyzed field was unchanged during the 6-hr period (taken as 3 hr before and after synoptic time). For this reason the cloud trajectories sometimes show abrupt changes in direction or speed at the change from one 6-hr period to the next. The trajectories were usually computed for 24 hr, or until the cloud was several hundred miles from the site. Figures 71 to 81 show the plotted trajectories for the Upshot-Knothole test series.
