16. Abstract

Based on climatological data from airports where weather observations are taken, a climatological value is derived for most U.S. airports. This value represents the percentage of time over a period of a year that one could expect to encounter ceilings less than or equal to 1,500 feet and/or visibilities less than or equal to 3 miles. The report indicates how the data was derived and assumptions made.

1. INTRODUCTION AND PURPOSE

1.1 Purpose

Inferred climatological listings herein are for 14,296 airports in the 48 contiguous United States. The data are intended for use in preliminary allocation (planning) of funds and/or equipment where potential of bad weather influences the priority among competing airports.

1.2 Limitations of the Data

A previous study performed by NOAA's National Climatic Center (Reference 1) for the Federal Aviation Administration compiled climatological data for 271 airports where detailed weather records were available over a 5-year period, or longer. For some major airports where data were needed and 5 years of data were not available, substitution was made of data from a nearby airport. The time period of the study, 5 to 15 years, was selected to assure that any climatological bias due to recent environmental pollution weighted FAA's allocation of Facilities and Equipment to favor current, not past, needs.

This present study was performed to extend the available data to as many airports as possible, rather than just to those where detailed weather records are available. The goal was to infer a climatological factor, the frequency with which "marginal" VFR weather (or worse) could be expected at any airport where FAA might want to consider allocation of equipment. The process used was to make quite simplistic assumptions, described later, that would allow computerized analysis of the 3-dimensional location (direction, distance and elevation) of the target airport with respect to each climatological station listed in reference 1 that was within 200 miles distance and 500 ft elevation of the target airport. Computer selection of the inferred climatology for the target airport was by a voting procedure from all available climatological stations falling within this cylinder of 200-mile-radius by $\pm$500 ft - elevation-difference.

Among others, the following important factors that may affect local climatology were ignored, both for the climatological station and for the target airport:

1. Slope of terrain and prevailing wind direction and speed.

2. Presence of large water bodies.

3. Relative distances and height differences from windward mountain ridges.

Because of these weaknesses, inferred data in the listings should not be used for any purpose other than initial evaluation of priority for allocation of equipment or similar planning purposes. The data are clearly not correct climatological data; rather they are chosen with

some probability (not defined) that the greatest frequency of marginal weather indicated by nearby climatological stations is the one selected for the target airport. The inferred climatology may be either better or worse than the real climatology at the target airport, with some bias toward worse.

2. AIRPORT SELECTION AND DATA PROCESSING

2.1 Selection of Airports

Airports were selected from data provided by FAA's National Flight Data Center (NFDC). Selection was limited to airports in the 48 contiguous states because of the large distances and known climatological vagaries between available climatological stations in Alaska, Hawaii and the island territories. An airport within the 48 states was omitted for any one of the following reasons:

1. The NFDC data base did not provide verifiable location data, including latitude and longitude.

2. The NFDC listing did not provide elevation data.

3. No climatology station was within 200 miles and/or $\pm$500 ft elevation.

2.2 Data Processing

For each airport screened by the computer to have an inferred climatological value, the following procedures were employed:

1. A search was made for a climatological station within 20 miles and $\pm$200 ft elevation difference from the target airport. If one or more were found, the climatological frequency of $\leq$ 1500 ft ceiling and/or 3 miles visibility ($\leq$ 1500/3) for the closest climatological station was assigned to the target airport.

2. If no assignment was made in step 1, a similar search was made within 200 miles and $\pm$ 200 ft elevation difference from the target airport. If one or more climatological stations were found, selection was as follows:

   a. Data from the nearest one was chosen if two or more had a frequency of $\leq$ 1500/3 agreeing within $\pm$ 2 percentage points.

   b. If no agreement was found within $\pm$ 2 percentage points, or if only one was found, data from the one having the highest frequency of $\leq$1500/3 was chosen.

3. If no assignment resulted from steps 1 or 2, the search was extended to 200 miles and $\pm$ 500 ft elevation difference and procedures for step 2 applied.

4. If no climatological station was found within 200 miles and ± 500 ft elevation difference, the station was not included in the listings.

2.2.1 Data Quality

For the 271 airports used in reference 1, the inferred climatological data and the real climatological data are the same; quality is very high. For nearby airports the inferred climatology has a high probability of being correct within a few percent. For airports in the 200 mile, plus or minus 500 ft range, however, inferred data may be quite suspect. So that the user may have some feel for the relative quality of the data, at least in a probabilistic sense, the climatological listing for each airport is preceded by two digits indicating quality.

As shown by the decoding table on alternate page listings, the quality numbers represent increments of 20 miles and elevation-differences of 50 ft. Thus, a number 3 in each quality column indicates the chosen climatological frequency is that for a climatological station between 41 and 60 miles away that had an elevation from 101 to 150 ft different than the target airport.

3. INFERRED CLIMATOLOGICAL LISTINGS AND THEIR USE (APPENDIX)

The listings of inferred climatological data are alphabetical by state and alphabetical by city within each state. The first column is the associated city (the city the airport is primarily designed to serve). The 2-letter state abbreviation follows, then the three or four alphanumeric call sign that is assigned that airport by FAA, and then the facility identification (usually the airport name, but may be the airport owner, the ranch name, etc.). The two "quality" columns follow the inferred climatological value, which is listed in whole percent and tenths. Thus, 6.9 means values of ≤1500/3 are inferred to exist 6.9% or .069 of the time.

3.1 Use of the Data

This study was performed as part of the effort in writing the "Priority Guidance for Installation of Automatic Weather Stations at Airports".

Obviously, the frequency of occurrence of bad weather is a significant factor in deciding priority for deploying automatic weather stations.

It became obvious that climatological data being developed for Automatic Weather Observation System deployment studies would apply to a great many equipment items FAA and other Government agencies may want to place at airports. Consequently this climatological study is being published separately so it will be available for wider usage.

One area where use seems potentially applicable is where FAA's establishment criteria" have in the past required counts of AIA's

(actual instrument aproaches) at airports to determine eligibility of, for example, ILS, MLS, REIL, etc. Since AIA's will no longer be counted, total operations with an appropriate climatological weighting may provide an acceptable substitute. Inferred climatological data could be weighted (either with linear or logarithmic weighting, as necessary) in such a way as to provide priority values closely approximating those obtained through use of AIA's.
