ABSTRACT

↓
A computer model to calculate the development of wall jet boundary layers downstream of multiple film-cooling slots is described. The differential equations for the conservation of mass, momentum and energy in an incompressible two-dimensional or axisymmetric flow are solved using a downstream-marching, iterative, implicit, finite-difference scheme. The turbulent transport of mass in a conventional wall boundary layer is described by means of an inner-outer two-layer eddy-viscosity model based on the Prandtl mixing-length hypothesis with Van Driest's modification in the near-wall region. Further alterations to include the effects of pressure gradients, heat and mass transfer are due to Cebeci and Smith. This basic model is extended to include cases with tangential fluid injection.

Computed velocity profiles indicate that the law of the wall is

ABSTRACT (Cont'd)

obeyed in the inner layer and that the outer wake-like layer strives to resume the velocity-defect relationship that existed upstream of the point of fluid injection in zero pressure-gradient flow with no heat or mass transfer.

Comparison between computed and experimental adiabatic wall temperature distributions in flows with heat transfer shows that the eddy-viscosity model is deficient in the near-slot region and tends to overestimate film-cooling efficiency. The absence of an eddy term to account for turbulence due to finite slot lip thickness is partly responsible for this overestimation.

Recommendations are made to validate the model in pressure-gradient flows and to improve the predictive capability in the near-slot region.

NOMENCLATURE

Symbols

- a denotes functional relationship in dimensionless velocity-profile expression.
- A is Van Driest's damping-length parameter or a coefficient of $u_{m,n-1}$ in the tridiagonally-banded system of equations.
- b is a constant in the dimensionless velocity-profile expression.
- B is a coefficient of $u_{m,n}$ in the tridiagonally-banded system of equations.
- C is a coefficient of $u_{m,n+1}$ in the tridiagonally-banded system of equations.
- d_1 is the injection slot width.
- d_2 is the injection slot length.
- D is the constant term in the tridiagonally-banded system of equations.
- f denotes a functional relationship.
- g_c is a constant in the momentum equation.
- H is the height of the finite-difference grid in the y-direction.
- ℓ is the mixing length.
- L is the distance in the x-direction from the injection slot entrance to the downstream end of the finite-difference grid.
- m is a dimensionless mass-flow parameter in Mukherjee's correlation, or m is the streamwise station number in the finite-difference grid.
- M is the total number of streamwise stations in the finite-difference grid.
- n is the transverse station number in the finite-difference grid.
- N is a parameter to account for pressure-gradient, heat and mass transfer effects in Van Driest's modification to the mixing length in the near-wall region, or N is the total number of transverse stations in the finite-difference grid.

NOMENCLATURE - Symbols (cont'd)

p	is static pressure.
p^+	is a dimensionless pressure-gradient parameter.
Pr	is the molecular Prandtl number.
Pr_t	is the turbulent Prandtl number
q	is an arbitrary parameter that is a function of x and y .
r	is the local radius in axisymmetric flow.
R	is the gas constant for main and injected streams.
Re_2	is Reynolds number based on the injection slot width and mean injection velocity.
T	is static temperature.
T'	is the fluctuating component of static temperature, or T' is static temperature from a previous iteration or station.
u	is the streamwise component of fluid velocity.
u'	is the fluctuating component of streamwise velocity.
v	is the transverse component of fluid velocity.
v'	is the fluctuating component of transverse velocity.
v_w	is the velocity of fluid being transferred across the wall.
v_w^+	is a dimensionless mass-transfer parameter.
w	is the thickness of the slot lip.
x	is the streamwise coordinate (measured along the wall).
Δx	is the streamwise grid interval.
y	is the transverse coordinate (measured normal to the wall).
Δy	is a characteristic transverse grid interval.
Δy_1	is the transverse grid interval in the grid zone closest to the wall. That is $\Delta y_1 = \Delta y$ for $0 \leq y \leq d_1/2$.

NOMENCLATURE - Symbols (cont'd)

- Δy_2 is the transverse grid interval in the intermediate grid zone. That is $\Delta y_2 = 10 \Delta y$ for $d_1/2 \leq y \leq 2d_1$.
- Δy_3 is the transverse grid interval in the outer grid zone. That is $\Delta y_3 = 100 \Delta y$ for $2d_1 \leq y \leq H$.
- α is the molecular thermal conductivity.
- α_t is the eddy thermal conductivity.
- β is the nondimensional distance in Mukherjee's film-cooling correlation.
- δ is the boundary-layer thickness.
- η is the film-cooling efficiency in Mukherjee's film-cooling correlation.
- κ is von Karman's mixing-length constant (equal to 0.435 in this report).
- λ is a proportionality constant relating the mixing length in the outer region to boundary-layer thickness.
- μ is molecular dynamic viscosity.
- ν is molecular kinematic viscosity.
- ν_t is eddy (kinematic) viscosity.
- ρ is static density.
- τ is local shear stress.

Subscripts

- e is in reference to the edge of the boundary layer.
- w depicts a value at the wall.
- 1 refers to the condition of the hot gas or main-stream fluid.
- 2 denotes the condition of the cooling air or injected fluid.

Superscripts

- k is zero for plane flow and unity for axisymmetric flow.
- +
- refers to dimensionless quantities.

A CALCULATION METHOD FOR CONVECTIVE HEAT AND MASS
TRANSFER IN MULTIPLY-SLOTTED FILM-COOLING APPLICATIONS (U)

by

S.B. Murray

1. INTRODUCTION

This report describes a computer model intended for use in the calculation of wall jet boundary layers downstream of multiple film-cooling slots. This model was developed at DRES as part of work to determine specifications for future military acquisitions.

Both at the time the project began and at time of writing the author is not aware of any computer model that is available, either commercially or through governmental sources, that fulfills the particular requirements, in part or in full, of the present application. Although the theory of turbulent flows has been a subject of interest for several decades, from the point of view of commercial software, the development of application packages is still in its infancy. For this reason, the author elected to write a special purpose program in order to meet the specific requirements of the aforementioned studies.

UNCLASSIFIED

Briefly, the model is applicable to incompressible, turbulent wall jet boundary layers with pressure-gradient, heat-transfer and mass-transfer effects in flows over two-dimensional or axisymmetric bodies with multiple film-cooling slots. For the engineering nature of the present work a relatively simple mixing model and differencing scheme have been employed. The theoretical model is described in Section 2 and details regarding the solution procedure are outlined in Section 3. Comparisons of prediction to experiment are presented in Section 4. Documented listings and a description of the program are included in Appendix A, while a user's guide and sample run appear in Appendix B.

2. THE THEORETICAL MODEL

The theory described in this report is based on numerical solution of the two-dimensional or axisymmetric, turbulent boundary-layer equations using a downstream-marching, iterative, implicit, finite-difference method. The turbulent transport terms in the boundary-layer equations are described by means of a two-layer eddy-viscosity model intended for use in the calculation of conventional turbulent wall boundary layers. This model has been extended to cases with tangential fluid injection.

2.1 The Governing Boundary-Layer Equations

The present calculations employ the incompressible turbulent boundary-layer equations in terms of time-averaged mean-flow quantities. For flow about two-dimensional and axisymmetric bodies at high Reynolds number the governing equations are:

Continuity

$$\frac{\partial}{\partial x} (r^k \rho u) + \frac{\partial}{\partial y} (r^k \rho v) = 0 \quad (1)$$

x-Momentum

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = - \frac{g_c}{\rho} \frac{dp}{dx} + \frac{1}{r^k \rho} \frac{\partial}{\partial y} \left\{ r^k \left[\mu \frac{\partial u}{\partial y} - \rho \overline{u'v'} \right] \right\} \quad (2)$$

Energy

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \frac{1}{r^k} \frac{\partial}{\partial y} \left\{ r^k \left[\frac{\mu}{Pr} \frac{\partial T}{\partial y} - \rho \overline{T'v'} \right] \right\} \quad (3)$$

State

$$p = \rho RT \quad (4)$$

with the following Boussinesq eddy-diffusivity assumptions for the Reynolds stress and heat-transfer terms:

$$\left. \begin{aligned} -\rho \overline{u'v'} &= \rho \nu_t \frac{\partial u}{\partial y} \\ -\rho \overline{T'v'} &= \rho \alpha_t \frac{\partial T}{\partial y} \end{aligned} \right\} \quad (5)$$

The exponent k is equal to zero for plane flow and equal to unity for axisymmetric flow. The coordinate system, shown in Figure 1, is curvilinear in which x and y are distances along and normal to the body surface, with u and v the velocity components within the boundary layer in the x - and y -directions, respectively. The static pressure, p , is assumed to be independent of y with quantities T , ρ and μ being the local fluid temperature, density and dynamic viscosity, respectively. The eddy viscosity, ν_t , and eddy thermal conductivity, α_t , are related by the turbulent Prandtl number:

$$Pr_t = \frac{\nu_t}{\alpha_t} \quad (6)$$

The boundary conditions associated with the above equations are:

Momentum

$$\left. \begin{aligned} u(x,0) &\approx 0, \\ v(x,0) &\approx v_w \text{ and} \\ \lim_{y \rightarrow \infty} u(x,y) &= u_e(x) \end{aligned} \right\} \quad (7)$$

Energy

$$\left. \begin{aligned}
 T(x,0) &= T_w & \text{or} \\
 \frac{\partial T}{\partial y}(x,0) &= \frac{\partial T}{\partial y}_w & \text{and} \\
 \lim_{y \rightarrow \infty} T(x,y) &= T_e(x)
 \end{aligned} \right\} (8)$$

where subscripts w and e denote conditions at the wall and at the outer edge of the boundary layer, respectively. These equations fulfill the requirements of no slip or mass injection at the wall as well as prescribing the streamwise distribution of either wall temperature or heat flux. The outer edge velocity, $u_e(x)$, and static temperature, $T_e(x)$, are obtained from experiment or an inviscid flow calculation and must be consistent with the streamwise distribution of static pressure, $p(x)$.

2.2 The Turbulent Transport of Momentum

Shear stress in a conventional turbulent wall boundary layer is treated herein by the use of a two-layer eddy-viscosity model based on Prandtl's mixing-length hypothesis and employing a modified version of Van Driest's (1956) analysis in the near-wall region.

2.2.1 The inner region

In the inner region, where response to changes in energy supply is immediate, the eddy viscosity is given by:

$$\nu_t = \kappa^2 y^2 [1 - \exp(-y/A)]^2 \left| \frac{\partial u}{\partial y} \right| \quad (9)$$

where κ is von Karman's mixing-length constant, equal to 0.435, and A is Van Driest's damping-length parameter, $26\nu(\tau_w/\rho)^{-1/2}$. Here τ_w is the wall shear stress and ν is the local fluid kinematic viscosity. Van Driest's modification results in a continuous distribution of shear stress from the laminar value in the viscous sublayer, through the transition layer where laminar and turbulent components of shear stress are comparable, and out into the fully turbulent layer.

As it stands, Equation 9 is applicable to incompressible boundary layers with negligible pressure-gradient and heat-transfer effects and zero mass transfer. By following Van Driest's modelling of the viscous sublayer Cebeci and Smith (1974) have generalized the damping-length parameter to account for these variations. In their formulation this parameter is given by:

$$A = \frac{26\nu}{N} \left(\frac{\tau_w}{\rho_w} \right)^{-1/2} \left(\frac{\rho}{\rho_w} \right)^{1/2} \quad (10)$$

where N is a factor defined below.

For flows with no mass transfer:

$$N = \left\{ 1 - 11.8 \left(\frac{\mu_w}{\mu_e} \right) \left(\frac{\rho_e}{\rho_w} \right)^2 p^+ \right\}^{1/2} \quad (11)$$

When mass transfer effects are included:

$$N = \left\{ \frac{\mu}{\mu_e} \left(\frac{\rho_e}{\rho_w} \right)^2 \frac{p^+}{v_w^+} \left[1 - \exp \left(11.8 \frac{\mu_w}{\mu} v_w^+ \right) \right] + \exp \left(11.8 \frac{\mu_w}{\mu} v_w^+ \right) \right\}^{1/2} \quad (12)$$

The dimensionless pressure-gradient and mass-transfer parameters, p^+ and v_w^+ , are defined by:

$$p^+ = - \frac{v_e}{u_\tau^3} \cdot \frac{g_c}{\rho_e} \frac{dp}{dx} \quad \text{and} \quad (13)$$

$$v_w^+ = \frac{v_w}{u_\tau} \quad (14)$$

where u_τ is the friction velocity at the wall, $(\tau_w/\rho_w)^{1/2}$, and v_w is the velocity of the fluid which is being transferred across the wall.

2.2.2 The outer region

In the outer wake-like region of a conventional turbulent boundary layer the characteristic time scale of the flow is very much larger than that of the inner region. Ideally, the calculations should account for long turbulence decay times so that the distribution of eddy

viscosity at any particular streamwise location depends on the upstream development of the outer layer.

One particularly accurate model for this region, based on the experimental findings of Wygnanski and Fiedler (1968) about the concept of intermittency, is presented by Dvorak (1973). His approach correlates the development of the outer region with conventional boundary-layer parameters such as the displacement thickness, δ^* , and shape factor, H . Unfortunately, this model is not very well suited to flows with large density gradients typical of the present application, since δ^* and H take on values which are outside the range over which the experimental data of the above researchers is valid. As a result, since implementation of the model at present is in support of film-cooling design, the approach due to Dvorak has been abandoned.

One suitable alternative is to employ the mixing-length theory but with a mixing-length formulation representative of the activity in the outer wake-like portion of the layer. Whereas the mixing length in the inner region is proportional to distance from the wall, Escudier (1965) suggests that in the outer region the mixing length should be proportional to the overall boundary layer thickness so that:

$$\begin{aligned} \ell &= \lambda \delta & \text{and} \\ v_t &= \lambda^2 \delta^2 \left| \frac{\partial u}{\partial y} \right| & \text{for } \frac{\lambda \delta}{\kappa} \leq y \leq \delta. \end{aligned} \quad (15)$$

Patankar and Spalding (1968) recommend values for λ and κ of 0.09 and 0.435, respectively. For $y \leq \lambda \delta / \kappa$ the inner-layer model of Equation 9 (with Cebeci and Smith's modifications) is applied.

2.2.3 Extension to tangential injection

The eddy-viscosity model just presented is intended for use in the calculation of conventional wall boundary layers. In the present work, it has been extended to include tangential fluid injection in a manner similar to that of Pai and Whitelaw (1970) and that of Dvorak.

As shown in Figure 2, there are two distinct types of wall jet boundary layers for the purpose of the present discussion. In case 1,

the wall jet does not possess enough momentum to completely entrain the remnant of the main-stream boundary layer. This gives rise to a velocity profile with a local jet maximum and a distinct velocity minimum. In case 2, the wall jet has sufficient momentum to consume this layer completely. The resulting velocity profile exhibits a wall jet maximum but no velocity minimum.

In order to construct an eddy-viscosity profile which is consistent with a given velocity distribution, it is assumed that as long as a wall jet maximum is present, the jet region and the remnant of the main-stream boundary layer behave as independent entities. The simple two-layer model presented in 2.2.1 and 2.2.2 is used to formulate the eddy-viscosity profile in the wall jet, starting at the wall and working outward into the fully turbulent region. The boundary-layer thickness used in this calculation is simply the distance from the wall to the point where the velocity maximum exists. Since the eddy viscosity is zero both at the wall (where $y = 0$) and at the point of maximum velocity (where $du/dy = 0$), it must pass through a maximum somewhere between these points. This will be referred to as maximum 1.

In a similar manner, the simple two-layer model is used to configure the eddy-viscosity distribution in the remnant of the main-stream boundary layer, starting in the free stream and working toward the wall. The boundary layer thickness employed in this computation is the distance from the wall to the point at the outer edge of the boundary layer where the velocity equals 99 percent of that in the free stream. In these calculations the eddy viscosity is zero at the outer edge (where $du/dy = 0$) and passes through a local maximum before returning to zero at a point (where $du/dy = 0$) defined as follows:

Case 1: the location of velocity minimum; and

Case 2: the location of wall jet local velocity maximum.

This eddy-viscosity maximum will be referred to as maximum 2.

As emphasized by Pai and Whitelaw, Launder and Spalding (1972) and Dvorak, strict application of the mixing-length hypothesis between

eddy-viscosity maxima 1 and 2 creates problems in that some gradients tend to infinity. To avoid this occurrence, Pai and Whitelaw simply fit a straight-line "bridge" between maxima. The approach of Dvorak, and the one taken here, is to fit a cosine fairing between maxima to make the eddy-viscosity profile continuous over the bridged region.

2.3 The Turbulent Transport of Heat

Before the temperature distribution within a boundary layer can be predicted, it is necessary to prescribe the distribution of thermal conductivity, α_t , for use in Equation 5. The most common and extensively used hypothesis is that due to Reynolds who assumed that heat and momentum are transferred by the same mechanism. With this assumption the eddy coefficients for momentum and heat transport are identical and yield a turbulent Prandtl number of unity.

For the purpose of predicting heat transport in film-cooling, however, an approach that has met with remarkable success is that of Kacker, Pai and Whitelaw (1969). These researchers used experimental data to derive an empirical Prandtl number distribution of the form:

$$\begin{aligned} Pr_t &= 1.75 - 1.25(y/\delta) \quad \text{for } 0 \leq y/\delta \leq 1 \quad \text{and} \\ Pr_t &= 0.5 \quad \quad \quad \text{for } y/\delta \geq 1. \end{aligned} \quad (16)$$

In the present study, this Prandtl number distribution is used in conjunction with the eddy-viscosity model of 2.2 to arrive at a suitable eddy-conductivity profile for use in solving the energy equation.

3. THE SOLUTION PROCEDURE

3.1 The Finite-Difference Grid Network

The grid network that is used to discretize the flow field downstream of the injection slot is shown for an arbitrary case in Figure 3. Cooling air enters the slot of width d_1 and is directed a distance d_2 in the downstream direction before emerging from the slot to interact with the main stream. The wall which separates the secondary and primary flows is of thickness w . A constant grid interval of Δx is employed in the stream-

wise direction between $x = d_2$ and $x = L$. In the y -direction, where the characteristic scale of turbulence changes markedly with increasing distance from the wall, a three-zone grid spacing is used. In film-cooling or other studies involving slot blowing it seems particularly appropriate to choose grid intervals and grid zone boundaries as follows:

$$\begin{aligned}\Delta y_1 &= \Delta y' & \text{for} & \quad 0 \leq y \leq d_1/2, \\ \Delta y_2 &= 10 \Delta y' & \text{for} & \quad d_1/2 \leq y \leq 2d_1 \text{ and} \\ \Delta y_3 &= 100 \Delta y' & \text{for} & \quad 2d_1 \leq y \leq H,\end{aligned}$$

where $\Delta y'$ is some appropriately small distance in comparison to the viscous sublayer thickness.

3.2 The Finite-Difference Equations

Since the theoretical models used to describe the turbulent transfer of mass and heat in this application are not among the most sophisticated available, there is no need to utilize a high order finite-difference scheme. In the present calculations three-point central differencing in the y -direction and three-point upstream differencing in the x -direction will suffice. With this order of differencing, first and second partial derivatives of any variable q with respect to y are approximated by:

$$\begin{aligned}\frac{\partial q}{\partial y} &\doteq \frac{q_{m,n+1} - q_{m,n-1}}{2\Delta y} & \text{and} \\ \frac{\partial^2 q}{\partial y^2} &\doteq \frac{q_{m,n+1} - 2q_{m,n} + q_{m,n-1}}{\Delta y^2}\end{aligned}$$

at a given point (m,n) in the interior of the grid. Similarly, the first partial derivative with respect to x of the same function at that point is approximated by:

$$\frac{\partial q}{\partial x} \doteq \frac{3q_{m,n} - 4q_{m-1,n} + q_{m-2,n}}{2\Delta x}.$$

3.2.1 The momentum equation in finite-difference form

With these approximations the left side of the momentum equation (Equation 2) becomes:

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \approx u'_{m,n} \left[\frac{3u_{m,n} - 4u_{m-1,n} + u_{m-2,n}}{2\Delta x} \right] + v'_{m,n} \left[\frac{u_{m,n+1} - u_{m,n-1}}{2\Delta y} \right]$$

where $u'_{m,n}$ and $v'_{m,n}$ are the values of $u_{m,n}$ and $v_{m,n}$ from the previous iteration. The use of these previously-computed quantities is necessary for two reasons. Firstly, the presence of $u'_{m,n}$ above eliminates what would otherwise be a second order term in $u_{m,n}$, thus complicating the solution procedure. Secondly, current values of transverse velocity $v_{m,n}$ are not available for the solution of the momentum equation since these are calculated by integrating the continuity equation once the distribution of streamwise velocity is known. Hence the transverse velocity from the previous iteration $v'_{m,n}$ is used. Since the distributions of eddy viscosity and streamwise velocity must be made consistent through iteration anyway, the use of these previously-computed quantities does not necessitate any additional iteration. Note that as consistency between eddy viscosity and streamwise velocity occurs $u'_{m,n}$ and $v'_{m,n}$ will approach $u_{m,n}$ and $v_{m,n}$, respectively.

Applying the chain rule to the right side of the momentum equation and expressing it in finite-difference form gives:

$$\begin{aligned} & - \frac{g_c}{\rho} \frac{dp}{dx} + \frac{1}{r^k \rho} \frac{\partial}{\partial y} \left\{ r^k \rho (v + v_t) \frac{\partial u}{\partial y} \right\} \\ & \approx \frac{-g_c}{\rho_{m,n}} \left[\frac{3p_m - 4p_{m-1} + p_{m-2}}{2\Delta x} \right] + (v + v_t)_{m,n} \left[\frac{u_{m,n+1} - 2u_{m,n} + u_{m,n-1}}{\Delta y^2} \right] \\ & + \left[\frac{u_{m,n+1} - u_{m,n-1}}{2\Delta y} \right] \left[\frac{(v + v_t)_{m,n+1} - (v + v_t)_{m,n-1}}{2\Delta y} \right] \\ & + \frac{(v + v_t)_{m,n}}{\rho_{m,n}} \left[\frac{u_{m,n+1} - u_{m,n-1}}{2\Delta y} \right] \left[\frac{\rho_{m,n+1} - \rho_{m,n-1}}{2\Delta y} \right] \end{aligned}$$

$$+ \frac{(v + v_t)_{m,n}}{r_{m,n}^k} \left[\frac{u_{m,n+1} - u_{m,n-1}}{2\Delta y} \right] \left[\frac{r_{m,n+1}^k - r_{m,n-1}^k}{2\Delta y} \right]$$

Equating left and right sides and gathering like terms gives:

$$Au_{m,n-1} + Bu_{m,n} + Cu_{m,n+1} = D \quad (16)$$

$$\begin{aligned} \text{where } A = & 2v'_{m,n}\Delta y - (v + v_t)_{m,n+1} + (v + v_t)_{m,n-1} \\ & + (v + v_t)_{m,n} \left\{ 4 - \frac{\rho_{m,n+1} - \rho_{m,n-1}}{\rho_{m,n}} - \frac{r_{m,n+1}^k - r_{m,n-1}^k}{r_{m,n}^k} \right\}, \\ B = & - \frac{6u'_{m,n}\Delta y^2}{\Delta x} - 8(v + v_t)_{m,n}, \\ C = & - 2v'_{m,n}\Delta y + (v + v_t)_{m,n+1} - (v + v_t)_{m,n-1} \\ & + (v + v_t)_{m,n} \left\{ 4 + \frac{\rho_{m,n+1} - \rho_{m,n-1}}{\rho_{m,n}} + \frac{r_{m,n+1}^k - r_{m,n-1}^k}{r_{m,n}^k} \right\}, \text{ and} \\ D = & 2u'_{m,n}\Delta y^2 \left\{ \frac{u_{m-2,n} - 4u_{m-1,n}}{\Delta x} \right\} + \frac{2g_c\Delta y^2}{\rho_{m,n}} \left\{ \frac{3p_m - 4p_{m-1} + p_{m-2}}{\Delta x} \right\}. \end{aligned}$$

The above coefficients are valid for all N points at a given streamwise station with the exception of those two points at the interface between grid zones and those two points at the wall and free-stream boundaries.

The criterion used to evaluate the coefficients at the grid-zone boundaries is one of equal velocity profile first derivatives (i.e., identical slopes). The wall boundary condition, namely that $u_w = 0$, is easily imposed by setting the B coefficient to unity and all others to zero. Likewise, the free-stream boundary condition is fixed by setting the B coefficient to unity, the D coefficient to u_e and all others to zero. The boundary conditions, in terms of these coefficients, are summarized in Table I below.

Boundary Condition	Coefficient			
	A	B	C	D
wall boundary	0	1	0	0
free-stream boundary	0	1	0	u_e
grid-zone interface	10	- 11	1	0

Table I: Coefficients for Use in Equation 16 to Depict Boundary Conditions for the Momentum Equation.

With the aid of these boundary conditions Equation 16 is written for all points at a given streamwise station to form a system of N algebraic equations in tridiagonally-banded form (which is solvable by rapid means).

3.2.2 The continuity equation in finite-difference form

Having solved the momentum equation the distribution of streamwise velocity is known. Values of transverse velocity can now be computed by integrating the continuity equation. In finite-difference form Equation 1 is written at any point $(m, n-\frac{1}{2})$ using three-point differencing to yield the transverse velocity at point (m, n) :

$$v_{m,n} = \frac{(r^k \rho v)_{m,n-1} - \Delta y \frac{\partial}{\partial x} (r^k \rho u)_{m,n-\frac{1}{2}}}{(r^k \rho)_{m,n}}$$

$$\text{where } \frac{\partial}{\partial x} (r^k \rho u)_{m,n-\frac{1}{2}} = \frac{1}{2} \left(\frac{\partial}{\partial x} (r^k \rho u)_{m,n-1} + \frac{\partial}{\partial x} (r^k \rho u)_{m,n} \right).$$

The streamwise derivatives are evaluated using the three-point upstream differencing formulation presented earlier.

Starting at the wall where $v_{m,1}$ is either zero or specified by a boundary-layer bleed relationship, the above equation is written at $(m, 1\frac{1}{2})$ in order to compute $v_{m,2}$. It is then written at $(m, 2\frac{1}{2})$ to give $v_{m,3}$, and so on, until $v_{m,n}$ is known for all $1 \leq n \leq N$.

3.2.3 The energy equation in finite-difference form

The energy equation (Equation 3) is of a form identical to that of the momentum equation with the pressure-gradient term omitted. Consequently, the differential equation reduces to a system of linear algebraic equations in tridiagonally-banded form as did the momentum equation. The coefficients in this case are:

$$\begin{aligned}
 A &= 2v_{m,n}\Delta y - (\alpha + \alpha_t)_{m,n+1} + (\alpha + \alpha_t)_{m,n-1} \\
 &\quad + (\alpha + \alpha_t)_{m,n} \left\{ 4 - \frac{\rho_{m,n+1} - \rho_{m,n-1}}{\rho_{m,n}} - \frac{r_{m,n+1}^k - r_{m,n-1}^k}{r_{m,n}^k} \right\}, \\
 B &= - \frac{6u_{m,n}\Delta y^2}{\Delta x} - 8(\alpha + \alpha_t)_{m,n}, \\
 C &= - 2v_{m,n}\Delta y + (\alpha + \alpha_t)_{m,n+1} - (\alpha + \alpha_t)_{m,n-1} \\
 &\quad + (\alpha + \alpha_t)_{m,n} \left\{ 4 + \frac{\rho_{m,n+1} - \rho_{m,n-1}}{\rho_{m,n}} + \frac{r_{m,n+1}^k - r_{m,n-1}^k}{r_{m,n}^k} \right\}, \text{ and} \\
 D &= 2u_{m,n}\Delta y^2 \left\{ \frac{T_{m-2,n} - 4T_{m-1,n}}{\Delta x} \right\}
 \end{aligned}$$

with boundary conditions as given in Table II below.

Boundary Condition	Coefficient			
	A	B	C	D
wall boundary	0	1	0	T_w
free-stream boundary	0	1	0	T_e
grid-zone interface	10	- 11	1	0

Table II: Coefficients for Use in Equation 16 to Depict Boundary Conditions for the Energy Equation.

The wall temperature, T_w , may be specified explicitly or in an implicit fashion such as a temperature-gradient boundary condition (which is more difficult to handle). The latter is particularly common when radiative heat transfer is taking place between the wall and another body. In order to solve the temperature-gradient case without making the algebraic equations non-linear, a guess is made at the wall temperature and the corresponding radiative heat flux is computed. This flux fixes the temperature gradient at the wall, thereby yielding a solution to the system of algebraic equations which represent the differential energy equation. Once a solution is generated the validity of first guess becomes apparent and, if necessary, the procedure is repeated until convergence on wall temperature is achieved.

3.3 The Downstream-Marching Iterative Solution Procedure

The system of parabolic differential Equations (1) through (3) with the turbulent momentum and heat transport assumptions of Sections 2.2 and 2.3 is solved using a downstream-marching, iterative, finite-difference solution algorithm. Three-point upstream differencing with downstream marching allows the velocity, temperature, eddy-viscosity and eddy-conductivity profiles to be computed at successive streamwise locations using information from only the two neighbouring upstream stations. For the purpose of starting the calculations, certain information (such as boundary layer thickness, free-stream and jet velocities and temperatures, etc.) is supplied by the user and utilized with formulations such as the "law of the wall" and Coles' (1956) "law of the wake" to construct upstream velocity and temperature profiles.

A flow chart describing the iterative solution procedure appears in Figure 4. Upon arriving at a new streamwise location, the first step is to assume a temperature profile, $T(y)$, at that station. This is readily done through extrapolation with the aid of temperature profiles from upstream locations. In conjunction with the static pressure, $p(x)$, this temperature distribution is used to compute density, dynamic-viscosity and kinematic-viscosity profiles, $\rho(y)$, $\mu(y)$ and $\nu(y)$, respectively. Next, in a manner identical to that above, assumptions must be made about the

distributions of both streamwise and transverse components of velocity, $u(y)$ and $v(y)$, respectively. Once these profiles are established, a corresponding eddy-viscosity profile, $\nu_t(y)$, is easily computed using the theoretical model presented in Section 2.2 along with the velocity gradient, $\partial u / \partial y$. The momentum equation can now be solved using the distributions of transverse velocity and eddy viscosity to yield a new streamwise velocity profile, $u'(y)$. The continuity equation then dictates a new transverse velocity profile, $v'(y)$. If these profiles are not in agreement with those that were initially assumed, $u(y)$ and $v(y)$ are replaced by $u'(y)$ and $v'(y)$ and the procedure is repeated until $u(y)$, $v(y)$ and $\nu_t(y)$ become consistent.

Once the above profiles are refined through convergence the energy equation is tackled. An eddy-conductivity profile, $\alpha_t(y)$, is calculated from the eddy-viscosity profile and assumptions about the turbulent Prandtl number, as presented in Section 2.3. This eddy-conductivity profile, along with the distributions of streamwise and transverse velocity computed above, is used to solve the energy equation for a new temperature profile, $T'(y)$. If it agrees with the initial assumption, $T(y)$, calculations at the streamwise station in question are now complete. If agreement is not achieved, then $T(y)$ is replaced by $T'(y)$ and calculations at this station are performed again from the start, including those for $u(y)$, $v(y)$ and $\nu_t(y)$.

A documented program listing and description of variables appear in Appendix A. A user's guide is presented in Appendix B.

4. RESULTS AND DISCUSSION

The applicability of Prandtl's mixing-length hypothesis to wall jet flows with heat transfer need not be questioned as this has been the subject of many research projects in the past. What is of importance presently is to ensure that this hypothesis has been incorporated correctly into the computer model.

One of the most reliable checks is to plot computed velocity profiles in the form u/u_τ versus $u_\tau y/\nu$ in order to examine the near-wall and law of the wall regions of the boundary layer. Figure 5 shows six

profiles plotted in this manner for the case of zero pressure-gradient flow with no heat or mass transfer. Two profiles at various streamwise locations, x/d_1 , are plotted for each of three nominal velocity ratios, u_2/u_1 . The solid line shows the velocity profile obtained by integrating the shear stress equation over the region of constant stress with the Prandtl mixing-length formula characterizing the turbulent component. With these assumptions the velocity profile is of the form:

$$u^+ = \int_0^{y^+} \frac{2}{b + [b^2 + 4a(y^+)]^{1/2}} dy^+ \quad (17)$$

where $u^+ = u/u_\tau$, $y^+ = u_\tau y/\nu$, $b = 1$ and $a(y^+) = (\kappa y^+)^2 [1 - \exp(-y^+/A^+)]^2$. Here A^+ is Van Driest's damping-length constant, equal to 26. Agreement between Equation 17 and computed profiles is excellent.

Whereas response to changes in energy supply is immediate in the inner region, the outer region of the boundary layer has a structure which is wake-like in nature and, as a result, the characteristic time scale of the flow is much larger than that of the inner region. Therefore, one would not expect this portion of the wall jet boundary layer to react instantaneously to the injection process at the wall but, over a period of time and after a substantial distance downstream, to adjust itself accordingly. This argument is readily supported by examining velocity-defect profiles of the type first illustrated by Clauser (1956). Figure 6 shows profiles at five stations downstream of an injection slot in zero pressure-gradient flow with no heat or mass transfer. The velocity-defect profile for the main-stream boundary layer, depicted by solid circles, follows the classic relationship identified by Clauser. However, a short distance downstream of the point of injection this relationship no longer holds since the friction velocity at the wall has quickly adjusted to the new conditions, whereas the outer region is still in a state of flux. Eventually, at some distance downstream of the slot, information regarding energy supply at the wall propagates throughout the entire boundary layer. As this happens the velocity-defect profiles approach the classic shape

once again.

The general features of mass and momentum transport, as calculated by the numerical method, appear to be correct judging from velocity profiles in each of the inner and outer layers. In order to verify the correctness of predictions about mass and heat transport, adiabatic wall temperature profiles downstream of an injection slot are plotted in Figure 7 for a variety of main-stream to secondary-stream velocity ratios and main-stream boundary layer dimensional variations. As before, all computations relate to flow development under zero pressure-gradient conditions. For the sake of comparison with other data results are plotted in the form suggested by Mukherjee (1976). The solid line in the figure is the mean adiabatic wall temperature distribution deduced from a variety of film-cooling data surveyed by the above researcher. The temperature distribution is expressed in terms of an efficiency, η , which is a function of non-dimensional distance, β . That is:

$$\eta = f(\beta)$$

$$\text{where } \eta = \frac{T_1 - T_w}{T_1 - T_2} \text{ and}$$

$$\beta = \left(\frac{u_2}{u_1} \text{Re}_2 \right)^{-0.25} \frac{x}{d_1 m} \quad (18)$$

$$\text{with } \text{Re}_2 = \frac{\bar{u}_2 d_1}{\nu_2} \text{ and}$$

$$m = \frac{\rho_2 u_2}{\rho_1 u_1} .$$

Here Re is a Reynolds number based on mean injection velocity and slot width. Subscripts 2, 1 and w refer to the cooling air, the hot gas and the wall, respectively.

The figure shows that in all cases the computer model predicts higher film-cooling efficiencies than Mukherjee's mean line. Discrepancies

between the two sources are smallest for both large values of β and small values of u_2/u_1 . These observations suggest that heat transfer is not properly predicted in regions where a strong wall jet exists. To further support this conclusion, results of computations performed for weak wall jets in a three-slot film-cooling configuration are shown graphically in Figure 8. Note that diverging isotherms in the near-slot regions are discontinuous a few slot widths downstream of each point of injection. These mark the locations at which the local wall jet velocity maxima disappear and consequently at which the wall jet boundary layer is assumed to have degenerated into a conventional wall boundary layer. The corresponding changes in the eddy-viscosity profile apparently increase the rate of mixing as evidenced by more rapidly diverging isotherms after the switchover to a different mixing model.

Another factor that is partly responsible for underestimating mixing and therefore overestimating cooling protection is the omission of an eddy-viscosity term to account for vorticity due to a finite slot lip thickness. Pai and Whitelaw have shown that in the near-slot region the influence of slot lip thickness is significant. In fact, according to their data, for an increase in lip thickness w/d_1 from 0.13 to 0.38 (for a density ratio ρ_2/ρ_1 of unity), a decrease in cooling efficiency of some five percent was observed at a distance of ten slot widths downstream of the point of injection.

5. CONCLUSIONS AND RECOMMENDATIONS

It would appear that both the inner and outer regions of the boundary layer are properly modelled since the near-wall, law of the wall and outer wake-like layers behave as they should in incompressible, zero pressure-gradient flow with no heat or mass transfer. In cases with heat transfer the film-cooling efficiencies predicted by the model are higher in the near-slot region than those quoted by Mukherjee by an amount ranging from two percent for $u_2/u_1 = 0.2$ to approximately ten percent for $u_2/u_1 = 1.0$. These differences appear to be the result of:

- i) underestimating turbulent mixing phenomena in that part of the mixing model used to evaluate eddy-viscosity when a local wall jet velocity maximum exists, and
- ii) not accounting for increased mixing due to vorticity caused by a finite slot lip thickness.

It is recommended that future work attempt to verify the predictive capability of the model in flows with pressure gradients and that modifications be made to the mixing model in the near-slot region to improve agreement between model calculations and heat-transfer correlations.

APPENDIX A

Description of Program FILM

APPENDIX A

Description of Program FILM

A detailed description of program FILM is presented in this appendix. Details are summarized under the following general headings;

- i) Description of Key Programming Modules, and
- ii) Description of Key Variables.

A documented program listing appears in Figure A-1.

Description of Key Programming Modules

<u>Name</u>	<u>Type</u>	<u>Purpose</u>
BLINT	sub	to integrate the boundary-layer velocity profile for the displacement thickness, momentum deficit thickness and velocity profile shape factor.
FILM	main	to synchronize the calling of major subroutines needed to initialize the boundary conditions, to compute the flow field and to store the computational results.
FLINK	sub	to read the outflow boundary conditions (from a disk file) from the last run to be executed and to construct the inflow boundary conditions for the present run, thereby linking the two flow fields.
FLMN1	sub	to read in general information about the coordinate system, grid network, ambient conditions, fluid dynamics and other phenomena that are characteristic of the run.
FLMN2	sub	to read in information about and to set up the streamwise boundary conditions including duct radius, duct wall slope, bleed velocity at the wall, free-stream temperature, static pressure and free-stream velocity.
FLMN3	sub	to read in information about and to set up the inflow boundary conditions including transverse grid step size and position, temperature, density and streamwise velocity.
FLMTD	sub	to calculate the distributions of eddy thermal conductivity and temperature throughout the boundary layer at a particular streamwise station.

<u>Name</u>	<u>Type</u>	<u>Purpose</u>
FLMVU	sub	to calculate the distributions of eddy viscosity, streamwise velocity and transverse velocity throughout the boundary layer at a particular streamwise station.
FMRCH	sub	to coordinate the downstream-marching procedure by calling subroutines to solve the differential equations for the conservation of mass, momentum and energy. FMRCH monitors convergence parameters and steps the solution from one streamwise station to the next.
FTIDY	sub	to store the outflow boundary conditions from a given run in a disk file for future reference.
GNINT	func	to fit a third-order polynomial to four data points and to return the value of the function for some specified point within the range over which the polynomial fit was evaluated.
MEW	func	to evaluate the dynamic viscosity of air as a function of temperature by interpolating in a table of temperatures and corresponding viscosities.
OTPT1	sub	to print out on the line printer the streamwise distribution of some quantity which is stored in the form of an array.
OTPT2	sub	to print out on the line printer the transverse distribution of some quantity which is stored in the form of an array.
QADD	sub	to allow the user to include any additional heat transfer terms in the heat balance at the duct wall.
THCON	func	to evaluate the thermal conductivity of air as a function of temperature by interpolating in a table of temperatures and corresponding thermal conductivities.
TRIDI	sub	to solve a tridiagonally-banded system of linear algebraic equations.
WLAW	sub	to solve for u in the law of the wall expression, given distance from the wall, y , and corresponding streamwise velocity, u . A Newton-Raphson root-finding technique is employed.

Description of Key Variables

<u>Fortran Variable Name</u>	<u>Conven- tional Symbol</u>	<u>Description</u>
A	$A_{m,n}$	is an array which contains the A coefficients in the system of algebraic equations used to solve the differential equations.
AA	A^+	is Van Driest's damping-length parameter (equal to 26).
ALM	$\alpha_{m,n}$	is an array which contains the transverse distribution of thermal conductivity at streamwise station m.
ALPHA	$\alpha(x)$	is an array which contains the streamwise distribution of duct wall slope measured from the duct centre line (required for axisymmetric flow only).
ALPHU		is the slope of the duct wall, measured from the duct centre line, one station upstream of the point of injection (required for axisymmetric flow only).
AP		is a working array.
AQ		is a working array.
ATRB	$\alpha_{t,m,n}$	is an array which contains the transverse distribution of eddy thermal conductivity at streamwise station m.
AU		is a working array.
B	$B_{m,n}$	is an array which contains the B coefficients in the system of algebraic equations used to solve the differential equations.
C	$C_{m,n}$	is an array which contains the C coefficients in the system of algebraic equations used to solve the differential equations.
CF	c_f	is the skin friction coefficient.
COORD		is a flag that specifies the coordinate system. COORD positive implies flow over a body of revolution. Otherwise, plane flow is assumed.
D	$D_{m,n}$	is an array which contains the D coefficients in the system of algebraic equations used to solve the differential equations.

<u>Fortran Variable Name</u>	<u>Conven- tional Symbol</u>	<u>Description</u>
DDWIN		is the sum of DWIN and D1.
DISP	δ^*	is the displacement thickness of the boundary layer.
DPDX	$\frac{dp}{dx}$	is the streamwise gradient of static pressure.
DTDX	$\frac{dT}{dx}$	is the streamwise linear gradient of temperature.
DUDYi	$\frac{du}{dy}$	is the transverse gradient of streamwise velocity for any character i. The gradient at the wall is denoted by i = W. A maximum gradient is denoted by i = M.
DUEDX	$\frac{du}{dx}$	is the streamwise linear gradient of free-stream velocity.
DVDX	$\frac{dv}{dx}$	is the streamwise linear gradient of transverse velocity.
DW		is the duct wall thickness.
DWALL		is the additive constant in the law of the wall expression used to create the inflow velocity profiles. It has a value of 5.24 in this study.
DWIN	w	is the slot lip thickness.
DX	Δx	is the grid step size in the x-direction.
DY	Δy_n	is an array which contains the transverse distribution of grid step size in the y-direction at all streamwise stations.
DYY	Δy_1	is the grid step size in the y-direction of the finest grid zone.
D1	d_1	is the injection slot width.
D2	d_2	is the length of the injection slot.
DELT1	δ_1	is the thickness of the main-stream boundary layer (just upstream of the point of injection) or the wall jet boundary layer.
DELT2	δ_2	is the thickness of the slot boundary layer or the distance from the wall to the point of wall jet maximum velocity.

<u>Fortran Variable Name</u>	<u>Conven- tional Symbol</u>	<u>Description</u>
FNRMT		is the fractional displacement norm of the temperature profile. It is used to monitor convergence of the profile.
FNRMU		is the fractional displacement norm of the velocity profile. It is used to monitor convergence of the profile.
GC	g_c	is a constant (equal to $32.2 \text{ lb}_m\text{-ft/lb}_f\text{-sec}^2$).
H	H	is the velocity profile shape factor.
IFi		is a disk file number for $1 \leq i \leq 10$.
IRECT		is a record pointer for the disk file retaining transverse temperature profiles.
IRECU		is a record pointer for the disk file retaining transverse profiles of streamwise velocity.
JDAT		is a flag used in setting up the inflow streamwise velocity profile.
JHEAT		is a flag that specifies whether or not heat transfer is to be included. JHEAT=0 implies that the energy equation will not be solved and that the temperature distribution specified as inflow boundary conditions will exist throughout the flow field. Otherwise, the energy equation will be solved.
JOUT		is the transverse station number corresponding to the location of YOUT.
JPAR		is a flag used in setting up the streamwise distributions of static pressure and free-stream velocity.
JPRES		is a flag used in setting up the streamwise distribution of static pressure.
JPRN		is a flag that indicates whether or not results of the computations will be printed out. JPRN=0 implies no line-printer output. Otherwise, output will result.
JRADL		is a flag used in setting up the streamwise distributions of duct radius and duct wall slope.

<u>Fortran Variable Name</u>	<u>Conven- tional Symbol</u>	<u>Description</u>
JSEP		is a flag used in setting up the streamwise distributions of static pressure and free-stream velocity.
JSL0T		is the slot number which identifies the flow field being computed presently.
JST0T		is the total number of slots in the structure being analyzed.
JSTRT		is a flag that indicates where data regarding the main stream is to be acquired. JSTRT=0 implies that such data will be supplied by the user as input. Otherwise, the outflow boundary conditions from the last run to be executed will be fetched from disk files and used as input conditions for the present run.
JT		is a flag used in setting up the inflow temperature profile.
JTOP		is the transverse station number corresponding to the location of YTOP.
JU		is a flag used in setting up the streamwise distribution of free-stream velocity.
JV		is a flag used in setting up the inflow transverse velocity profile.
JVEL		is a flag used in setting up the inflow streamwise and transverse velocity profiles.
JDEL1		is the transverse station number corresponding to the thickness DELT1.
JDEL2		is the transverse station number corresponding to the thickness DELT2.
KDGEN		is a flag indicating whether or not the wall jet boundary layer has degenerated to a conventional turbulent wall boundary layer.
KOUNT	m	is the streamwise station number.
M	M	is the number of stations in the streamwise direction at which computations are performed.
MEWAL	μ_w	is the fluid dynamic viscosity at the wall.

<u>Fortran Variable Name</u>	<u>Conven- tional Symbol</u>	<u>Description</u>
MOM	θ	is the momentum deficit thickness of the boundary layer.
N	N	is the number of stations in the transverse direction at which computations are performed.
NC		is a four-element array that usually contains station numbers corresponding to the wall, any grid-grid interface and the edge of the boundary layer.
NDIM		is the number of real elements in a file record (1000 in this program).
NEW	ν	is the local fluid kinematic viscosity.
NOLD		is N for the last run to be executed.
N1		is the transverse station number that corresponds to distance d_1 from the wall.
N2		is the transverse station number that corresponds to distance $(d_1 + w)$ from the wall.
NC1		is the transverse station number at the interface between fine (grid zone 1) and medium (grid zone 2) grids.
NC2		is the transverse station number at the interface between medium (grid zone 2) and coarse (grid zone 3) grids.
PATM	P_a	is the ambient pressure outside the duct. This pressure may be required for computing heat transfer from the duct to the surroundings in subroutine QADD.
PI	π	is a constant (equal to 3.1415926).
PMAIN		is the static pressure in the duct one station upstream of the point of injection.
PPLUS	p^+	is the dimensionless pressure-gradient parameter for use in modifying Van Driest's near-wall mixing-length expression.
PR	p_m	is the static pressure at streamwise station m.
PRES	$p(x)$	is an array which contains the streamwise distribution of static pressure.

<u>Fortran Variable Name</u>	<u>Conven- tional Symbol</u>	<u>Description</u>
PRLAM	Pr	is the fluid molecular Prandtl number.
PRTi		is a term used in modifying the near-wall mixing-length expression. i ranges from 1 to 3.
PTRB	Pr _t	is the fluid turbulent Prandtl number.
PSLOT		is the static pressure in the injection slot one station upstream of the point of injection.
PARM1	Π ₁	is Coles' profile parameter for the main-stream boundary layer (just upstream of the point of injection).
PARM2	Π ₂	is Coles' profile parameter for the slot boundary layers.
PART2		is an array which contains the transverse distribution of the quantity $\frac{r_{m,n+1}^k - r_{m,n-1}^k}{r_{m,n}^k} .$
PART3		is an array which contains the transverse distribution of the quantity $\frac{\rho_{m,n+1} - \rho_{m,n-1}}{\rho_{m,n}} .$
PART4		is an array which contains the transverse distribution of the quantity $\frac{2\Delta y_{m,n}^2}{\Delta x} .$
PART5		is an array which contains the transverse distribution of the quantity $\frac{2\Delta y_{m,n}^2 (u_{m-2,n} - 4u_{m-1,n})}{\Delta x} .$
PART6		is an array which contains the transverse distribution of the quantity $\frac{2g_c \Delta y_{m,n}^2 (3p_m - 4p_{m-1} + p_{m-2})}{\Delta x} .$

Fortran Variable Name	Conven- tional Symbol	Description
PART7		is an array which contains the transverse distribution of the quantity $\frac{2\Delta y_{m,n}^2 (T_{m-2,n} - 4T_{m-1,n})}{\Delta x}.$
PM1	p_{m-1}	is the static pressure at streamwise station m-1.
PM2	p_{m-2}	is the static pressure at streamwise station m-2.
QWALL	$q_{w,m}$	is the net heat transfer from the duct wall at a given streamwise station.
RAD	R_m	is the duct radius at streamwise station m (used for axisymmetric flow only).
RADUP		is the duct radius one station upstream of the point of injection (required for axisymmetric flow only).
RDIUS	$R(x)$	is an array which contains the streamwise distribution of duct radius (required for axisymmetric flow only).
RGAS	R	is the gas constant for use in the equation of state for both streams.
RLOC	$r_{m,n}$	is an array which contains the transverse distribution of local radius at streamwise station m (required for axisymmetric flow only).
RO	$\rho_{m,n}$	is an array which contains the transverse distribution of density at streamwise station m.
ROEE	ρ_e	is the density at the edge of the boundary layer.
ROEUE	$\rho_e u_e$	is the product of density and streamwise velocity at the edge of the boundary layer.
ROWAL	ρ_w	is the fluid density at the wall.
RAD1	R_{m-1}	is the duct radius at streamwise station m-1 (required for axisymmetric flow only).
RAD2	R_{m-2}	is the duct radius at streamwise station m-2 (required for axisymmetric flow only).
RLOC1	$r_{m-1,n}$	is an array which contains the transverse distribution of local radius at streamwise station m-1 (required for axisymmetric flow only).

<u>Fortran Variable Name</u>	<u>Conven- tional Symbol</u>	<u>Description</u>
RLOC2	$r_{m-2,n}$	is an array which contains the transverse distribution of local radius at streamwise station m-2 (required for axisymmetric flow only).
R01	$\rho_{m-1,n}$	is an array which contains the transverse distribution of density at streamwise station m-1.
R02	$\rho_{m-2,n}$	is an array which contains the transverse distribution of density at streamwise station m-2.
SCRAP		is a working array.
TATM	T_a	is the ambient temperature outside the duct. This temperature may be required for computing heat transfer from the duct to the surroundings in subroutine QADD.
TFREE	T_{e_m}	is the temperature in the core of the main stream at station m.
TINF	$T_e(x)$	is an array which contains the streamwise distribution of free-stream temperature.
TM	$T_{m,n}$	is an array which contains the transverse distribution of temperature at streamwise station m.
TMLAS	$T'_{m,n}$	is an array which contains the transverse distribution of temperature at streamwise station m from the last iteration in the solution of the energy equation.
TMOLD	$T'_{m,n}$	is an array which contains the transverse distribution of temperature at streamwise station m from the last iteration. The iteration in question is one necessitated when heat transfer from the wall is a function of the unknown wall temperature.
TNLIM		is the value that the temperature-profile fractional displacement norm must assume before convergence is sufficient.
TWMAX	$T_{w_{max}}$	is the maximum temperature that the wall can assume. If at any time during the run the wall temperature should exceed this value the job is automatically terminated in a controlled manner.
TINF1		is the uniform temperature of the main stream.
TINF2		is the uniform temperature of the injected stream.

<u>Fortran Variable Name</u>	<u>Conven- tional Symbol</u>	<u>Description</u>
TM1	$T_{m-1,n}$	is an array which contains the transverse distribution of temperature at streamwise station m-1.
TM2	$T_{m-2,n}$	is an array which contains the transverse distribution of temperature at streamwise station m-2.
UEE	u_e	is the streamwise velocity at the edge of the boundary layer.
UFREE	u_{e_m}	is the streamwise velocity in the core of the main stream at station m.
UINF	$u_e(x)$	is an array which contains the streamwise distribution of free-stream velocity.
UM	$u_{m,n}$	is an array which contains the transverse distribution of streamwise velocity at streamwise station m.
UMLAS	$u'_{m,n}$	is an array which contains the transverse distribution of streamwise velocity at streamwise station m from the last iteration in the solution of the momentum equation.
UNLIM		is the value that the velocity-profile fractional displacement norm must assume before convergence is sufficient.
UTAU	u_τ	is the friction or shear velocity.
UDEL1	u_1	is the streamwise velocity at the edge of the main-stream boundary layer.
UDEL2	u_2	is the wall jet maximum streamwise velocity or the streamwise velocity at the edge of the slot boundary layer.
UM1	$u_{m-1,n}$	is an array which contains the transverse distribution of streamwise velocity at streamwise station m-1.
UM2	$u_{m-2,n}$	is an array which contains the transverse distribution of streamwise velocity at streamwise station m-2.
VM	$v_{m,n}$	is an array which contains the transverse distribution of transverse velocity at streamwise station m.
VSC	$v_{m,n}$	is an array which contains the transverse distribution of kinematic viscosity at streamwise station m.
VTMJ	$v_{t_{\max_1}}$	is the eddy-viscosity maximum in the jet region of the wall jet boundary layer.

<u>Fortran Variable Name</u>	<u>Conven- tional Symbol</u>	<u>Description</u>
VTMM	$v_{t_{\max_2}}$	is the eddy-viscosity maximum in the outer region of the wall jet boundary layer.
VTRB	$v_{t_{m,n}}$	is an array which contains the transverse distributions of eddy viscosity at streamwise station m .
VWAL	v_{w_m}	is the bleed velocity at the wall at streamwise station m .
VWALL	$v_w(x)$	is an array which contains the streamwise distribution of bleed velocity at the wall.
VWPLS	v_w^+	is the dimensionless mass-transfer parameter for use in modifying Van Driest's near-wall mixing-length expression.
VM1	$v_{m-1,n}$	is an array which contains the transverse distribution of transverse velocity at streamwise station $m-1$.
VM2	$v_{m-2,n}$	is an array which contains the transverse distribution of transverse velocity at streamwise station $m-2$.
X	x	is the streamwise coordinate.
XH	H	is the height of the grid network, measured from the duct wall.
XK	κ	is von Karman's mixing-length constant (equal to 0.435).
XL	L	is the distance from the entrance of the injection slot to the downstream end of the grid network.
XLAMB	λ	is a proportionality constant, equal to 0.09, relating the mixing length and boundary-layer thickness.
XMASS	m_2	is the mass of fluid exiting the injection slot.
XOLD		is an array which contains the transverse distribution of some quantity at the outflow boundary of the last flow field to be computed.
Y	y_n	is an array which contains the transverse distribution of distance from the wall at all streamwise stations.
Y MIX	ℓ	is the mixing length.
YOLD		is an array which contains the transverse distribution of distance from the wall at the outflow boundary of the last flow field to be computed.

<u>Fortran Variable Name</u>	<u>Conven- tional Symbol</u>	<u>Description</u>
YOUT	$\frac{\delta\lambda}{\kappa}$	is the point at which the inner and outer portions of the boundary layer intersect.
YTOP		is the transverse location of local maximum eddy viscosity VTMM.

C
C   THE PURPOSE OF THIS SUBROUTINE IS TO CALCULATE THE DISTRIBUTION
C   OF STREAMWISE VELOCITY, TRANSVERSE VELOCITY AND EDDY VISCOSITY
C   THROUGHOUT THE BOUNDARY LAYER AT A GIVEN STREAMWISE STATION. THIS
C   IS ACHIEVED BY
C
C   A) IDENTIFYING THE BOUNDARY LAYER TO BE OF THE WALL JET OR
C   CONVENTIONAL TYPE BY SEARCHING FOR A LOCAL VELOCITY
C   MAXIMUM,
C
C   B) CALCULATING AN EDDY-VISCOSITY PROFILE BASED ON A TWO-
C   LAYER MODEL WHICH EMPLOYS THE PRANDTL MIXING-LENGTH
C   HYPOTHESIS,
C
C   C) SOLVING A SYSTEM OF LINEAR ALGEBRAIC FINITE-DIFFERENCE
C   EQUATIONS WHICH APPROXIMATE THE DIFFERENTIAL EQUATION
C   FOR THE CONSERVATION OF MOMENTUM IN AN INCOMPRESSIBLE
C   TURBULENT BOUNDARY LAYER, AND
C
C   D) SOLVING THE CONTINUITY EQUATION IN FINITE-DIFFERENCE FORM
C   TO OBTAIN THE DISTRIBUTION OF TRANSVERSE VELOCITY THROUGH-
C   OUT THE BOUNDARY LAYER.

APPENDIX B

A Guide to the Use of Program FILM

APPENDIX B

A Guide to the Use of Program FILM

The purpose of this appendix is to acquaint the user with the Fortran program so that he is able to perform a successful execution. Details are outlined under the following headings;

- i) Setting Up a Data Deck for Program FILM, and
- ii) Sample Data Deck and Results.

Setting Up a Data Deck for Program FILM

1.0	<u>General Information</u>	<u>format</u>
<u>DATA:</u>	JPRN, COORD, JSTRT, JSLOT, JSTOT, JHEAT	6I2
JPRN	= 0 to omit printout of results at key points in the computations. Otherwise, a printout will be produced.	
COORD	= 0 for axisymmetric flow. Otherwise, plane flow is assumed.	
JSTRT	= 0 if data describing the main-stream conditions at inflow are to be specified by the user. Otherwise, output boundary conditions from the last run to be executed will be fetched from the disk and used to describe the main stream in the present run.	
JSLOT	is the slot number as identified by the user. It is present only for recording purposes.	
JSTOT	is the total number of slots in the application being investigated. It is present only for recording purposes.	
JHEAT	= 0 for cases where it is not necessary to solve the energy equation. In these cases the temperature profile that is specified at the inflow boundary is assumed to exist at all streamwise stations in the flow field.	
<u>DATA:</u>	D1, D2, DX, DYY, XL, XH, DW, DWIN	8F10.6
D1	is the slot width (inches).	
D2	is the length of the injection slot (inches).	

format

DX is the incremental distance between stations in the streamwise direction (inches).

DYY is the incremental distance between stations in the transverse direction of the finest grid zone (inches).

XL is the overall length of the surface over which the flow is to be computed. It is measured from the entrance of the injection slot to the downstream end of the grid (inches).

XH is the height of the grid network (inches), measured from the duct wall.

DW is the duct wall thickness (inches).

DWIN is the slot lip thickness (inches).

DATA: PATM, TATM, RGAS, TWMAX

4F12.6

PATM is ambient pressure (psia) on the exterior of the duct.

TATM is ambient temperature ($^{\circ}$ R) on the exterior of the duct.

RGAS is the gas constant for both injected and main streams ($\text{ft-lb}_f/\text{lb}_m - ^{\circ}$ R).

TWMAX is the maximum allowable wall temperature ($^{\circ}$ R) that the duct can assume. The run will terminate if the wall exceeds this temperature.

2.0 Input of Data Pertaining to Streamwise Boundary Conditions

2.1 Duct Radius and Wall Slope

DATA: JRADL

I2

JRADL is a flag to assist in setting up streamwise distributions of duct radius and wall slope. JRADL = 0 implies Case 1. Otherwise, Case 2 is assumed. Note that for plane flow this information is required only for recording purposes.

formatCase 1 (JRADL = 0)DATA: RADUP, RDIUS(1), ...RDIUS(J), ...RDIUS(M)8F10.6
per card

RADUP is the duct radius (inches) one station upstream of the point of injection.

RDIUS(J) is the duct radius (inches) at streamwise station J in the grid network.

DATA: ALPHU, ALPHA(1), ...ALPHA(J), ...ALPHA(M)8F10.6
per card

ALPHU is the duct wall slope (radians) one station upstream of the point of injection.

ALPHA(J) is the duct wall slope (radians) at streamwise station J in the grid network.

Case 2 (JRADL $\neq$ 0)DATA: A, B, C

3F10.6

A, B, C are coefficients in the equation, radius $R = A + Bs + Cs^2$, which specifies the duct wall shape. Here s is measured in inches along the duct centre line from the entrance of the injection slot. These coefficients allow the calculation of all radii (inches) and wall slopes (radians). For a duct of constant radius $B = C = 0$. For a tapered duct $C = 0$. See below.

format2.2 Wall Bleed VelocityDATA: JV

I2

JV is a flag to assist in setting up the streamwise distribution of wall bleed velocity. JV = 0 implies Case 1. Otherwise, Case 2 is assumed.

Case 1 (JV = 0)DATA: VWALL(1), ...VWALL(J), ...VWALL(M)8F10.6
per card

VWALL(J) is the wall bleed velocity (fps) at streamwise station J in the grid network.

Case 2 (JV $\neq$ 0)DATA: VWALL(1), DVDX

2F10.6

VWALL(1) is the wall bleed velocity (fps) at streamwise station 1 (the point of injection) in the grid network.

DVDX is the linear gradient of wall bleed velocity (fps/inch).

2.3 Free-Stream TemperatureDATA: JT

I2

JT is a flag to assist in setting up the streamwise distribution of free-stream temperature. JT = 0 implies Case 1. Otherwise, Case 2 is assumed.

Case 1 (JT = 0)DATA: TINF(1), ...TINF(J), ...TINF(M)8F10.6
per card

TINF(J) is the free-stream temperature ($^{\circ}$ R) at streamwise station J in the grid network.

Case 2 (JT $\neq$ 0)DATA: TINF(1), DTDX

2F11.6

format

TINF(1) is the free-stream temperature ($^{\circ}$ R) at streamwise station 1 (the point of injection) in the grid network.

DTDX is the linear gradient of free-stream temperature ($^{\circ}$ R/inch).

2.4 Free-Stream Velocity and Static Pressure

DATA: PSLOT, PMAIN

2F15.10

PSLOT is the static pressure (psia) in the slot one station upstream of the point of injection.

PMAIN is the static pressure (psia) in the main stream one station upstream of the point of injection.

DATA: JSEP

I2

JSEP is a flag to assist in setting up the streamwise distributions of free-stream velocity and pressure. JSEP = 0 implies Case 1. Otherwise, Case 2 is assumed.

Case 1 (JSEP = 0)

DATA: UINF(1), ...UINF(J), ...UINF(M)

8F10.6
per card

UINF(J) is the streamwise component of free-stream velocity (fps) at streamwise station J in the grid network.

DATA: PRES(1), ...PRES(J), ...PRES(M)

8F10.6
per card

PRES(J) is the static pressure (psia) at streamwise station J in the grid network.

Case 2 (JSEP $\neq$ 0)

DATA: JPAR

I2

JPAR is a flag to assist in setting up the streamwise distributions of free-stream velocity and pressure. JPAR = 0 implies Case 2-1. Otherwise, Case 2-2 is assumed.

formatCase 2-1 (JSEP $\neq$ 0, JPAR = 0)DATA: UINF(1)

F10.6

UINF(1) is the streamwise component of free-stream velocity (fps) at streamwise station 1 (the point of injection) in the grid network.

DATA: JPRES

I2

JPRES is a flag to assist in setting up the streamwise distributions of free-stream velocity and pressure. JPRES = 0 implies Case 2-1-1. Otherwise, Case 2-1-2 is assumed.

Case 2-1-1 (JSEP $\neq$ 0, JPAR = 0, JPRES = 0)DATA: PRES(1), ...PRES(J), ...PRES(M)8F10.6
per card

PRES(J) is the static pressure (psia) at streamwise station J in the grid network.

Case 2-1-2 (JSEP $\neq$ 0, JPAR = 0, JPRES $\neq$ 0)DATA: PRES(1), DPDX

2F15.10

PRES(1) is the static pressure (psia) at streamwise station 1 (the point of injection) in the grid network.

DPDX is the linear gradient of static pressure (psia/inch).

Case 2-2 (JSEP $\neq$ 0, JPAR $\neq$ 0)DATA: PRES(1)

F10.6

PRES(1) is the static pressure (psia) at streamwise station 1 (the point of injection) in the grid network.

DATA: JU

I2

JU is a flag to assist in setting up the streamwise distributions of free-stream velocity and pressure. JU = 0 implies Case 2-2-1. Otherwise, Case 2-2-2 is assumed.

formatCase 2-2-1 (JSEP $\neq$ 0, JPAR $\neq$ 0, JU = 0)

DATA: UINF(1), ...UINF(J), ...UINF(M)

8F10.6
per card

UINF(J) is the streamwise component of free-stream velocity (fps)
at streamwise station J in the grid network.

Case 2-2-2 (JSEP $\neq$ 0, JPAR $\neq$ 0, JU $\neq$ 0)

DATA: UINF(1), DUEDX

2F10.6

UINF(1) is the streamwise component of free-stream velocity (fps)
at streamwise station 1 (the point of injection) in the
grid network.

DUEDX is the linear gradient of free-stream velocity (fps/inch).

3.0 Input of Data Pertaining to Inflow Boundary Conditions3.1 Transverse Velocity at the Point of Injection

DATA: JVEL

I2

JVEL is a flag, used in conjunction with JSTRT (specified pre-
viously), to assist in setting up the transverse distribu-
tion of transverse velocity. JVEL = 0 implies Case 1.
Otherwise, Case 2 is assumed.

Case 1 (JVEL = 0)

JSTRT = 0 implies Case 1-1. Otherwise, Case 1-2 is assumed.

Case 1-1 (JVEL = 0, JSTRT = 0)

DATA: VM1(1), ...VM1(J), ...VM1(N)

8F10.5
per card

VM1(J) is the transverse component of velocity (fps) at transverse
station J of the grid network.

Case 1-2 (JVEL = 0, JSTRT $\neq$ 0)

DATA: VM1(1), ...VM1(J), ...VM1(N1)

8F10.5
per card

format

VM1(J) is as above. Values of VM1(J) for $N1 < J \leq N$ will be read from a disk file.

Case 2 (JVEL $\neq$ 0)

JSTRT = 0 implies Case 2-1. Otherwise, Case 2-2 is assumed.

Case 2-1 (JVEL $\neq$ 0, JSTRT = 0)

DATA: none

VM1(J) is set to zero for all $1 \leq J \leq N$.

Case 2-2 (JVEL $\neq$ 0, JSTRT $\neq$ 0)

DATA: none

VM1(J) is set to zero for all $1 \leq J \leq N1$. Values of VM1(J) for $N1 < J \leq N$ will be read from a disk file.

3.2 Transverse Velocity One Station Upstream of Injection

Repeat 3.1 but for array VM2.

3.3 Temperature at the Point of Injection

DATA: JT

I2

JT is a flag, used in conjunction with JSTRT (specified previously), to assist in setting up the transverse distribution of temperature. JT = 0 implies Case 1. Otherwise, Case 2 is assumed.

Case 1 (JT = 0)

JSTRT = 0 implies Case 1-1. Otherwise, Case 1-2 is assumed.

formatCase 1-1 ($JT = 0$, $JSTRT = 0$)DATA: $TM1(1), \dots TM1(J), \dots TM1(N)$ 8F10.5
per card $TM1(J)$ is the temperature ($^{\circ}R$) at transverse station J of the grid network.Case 1-2 ($JT = 0$, $JSTRT \neq 0$)DATA: $TM1(1), \dots TM1(J), \dots TM1(N1)$ 8F10.5
per card $TM1(J)$ is as above. Values of $TM1(J)$ for $N1 < J \leq N$ will be read from a disk file.Case 2 ($JT \neq 0$) $JSTRT = 0$ implies Case 2-1. Otherwise, Case 2-2 is assumed.Case 2-1 ($JT \neq 0$, $JSTRT = 0$)DATA: $TINF2, TINF1$

2F10.5

 $TINF2$ is the uniform temperature ($^{\circ}R$) of the fluid in the injection slot. $TINF1$ is the uniform temperature ($^{\circ}R$) of the main-stream fluid.Case 2-2 ($JT \neq 0$, $JSTRT \neq 0$)DATA: $TINF2$

F10.5

 $TINF2$ is as above. The temperature profile for the main stream will be read from a disk file.3.4 Temperature One Station Upstream of InjectionRepeat 3.3 but for array $TM2$.

format3.5 Streamwise Velocity at the Point of InjectionDATA: JVEL

12

JVEL is a flag to assist in setting up the transverse distribution of streamwise velocity in the injection slot. JVEL = 0 implies Case 1. Otherwise, Case 2 is assumed.

Case 1 (JVEL = 0)DATA: UM1(1), ...UM1(J), ...UM1(N1)8F10.5
per card

UM1(J) is the streamwise component of velocity (fps) at transverse station J of the grid network.

Case 2 (JVEL $\neq$ 0)DATA: UDEL2, DELT2, PARM2

3F10.5

UDEL2 is the streamwise core velocity (fps) in the injection slot.

DELT2 is the thickness (inches) of both slot boundary layers. DELT2 must be less than half the slot width.

PARM2 is the law of the wake profile parameter for the slot boundary layers.

The above three parameters are used in conjunction with the law of the wall and the law of the wake to compute the streamwise velocity profile in the slot. The main-stream velocity profile is dealt with below. JSTRT = 0 implies Case 1. Otherwise, Case 2 is assumed.

Case 1 (JSTRT = 0)DATA: JVEL

12

JVEL is a flag, used in conjunction with JSTRT (specified previously), to assist in setting up the transverse distribution of streamwise velocity in the main stream. JVEL = 0 implies Case 1-1. Otherwise, Case 1-2 is assumed.

formatCase 1-1 (JSTRT = 0, JVEL = 0)DATA: UM1(N2), ...UM1(J), ...UM1(N)8F10.5
per card

UM1(J) is as above.

Case 1-2 (JSTRT = 0, JVEL $\neq$ 0)DATA: DELT1

F10.5

DELT1 is the main-stream boundary-layer thickness (inches).

DATA: JDAT

I2

JDAT is a flag, used in conjunction with JSTRT and JVEL, to assist in setting up the transverse distribution of streamwise velocity in the main stream. JDAT = 0 implies Case 1-2-1. Otherwise, Case 1-2-2 is assumed.

Case 1-2-1 (JSTRT = 0, JVEL $\neq$ 0, JDAT = 0)DATA: UDEL1, CF

2F15.10

UDEL1 is the main-stream outer edge velocity (fps).

CF is the skin friction coefficient associated with the main stream.

Case 1-2-2 (JSTRT = 0, JVEL $\neq$ 0, JDAT $\neq$ 0)DATA: UDEL1, PARM1

2F15.10

UDEL1 is as above.

PARM1 is the law of the wake profile parameter for the main-stream boundary layer.

Case 2 (JSTRT $\neq$ 0)DATA: none

The transverse distribution of streamwise velocity will be read from a disk file.

format

3.6 Streamwise Velocity One Station Upstream of Injection

Repeat 3.5 but for array UM2.

Sample Data Deck and Results

Consider the following hypothetical case. Air at an ambient temperature of 530°R is drawn through an injection of 2-inch length and 0.75-inch width which completely surrounds the circumference of a duct of 28-inch outside diameter and 0.06-inch wall thickness. The slot boundary layers are 0.25 inches thick and have a profile parameter (after Coles) of 0.1411, corresponding to a core velocity of 48.5 fps. This entrained stream interacts with a main exhaust stream whose core temperature and velocity are 1048°R and 151.9 fps, respectively. The main-stream boundary layer is 2 inches thick and exhibits a profile parameter of 0.55. Both flows are parallel with no transverse components of velocity, pressure gradients or heat transfer upstream of their interaction with one another. The gases, which are assumed to behave like air, mix in a turbulent fashion in a cylindrical duct of 12-inch overall length and 0.06-inch wall thickness. The static pressure varies linearly along the duct from 13.384368 to 13.389323 psia.

A grid network of 5.25-inch height and 10-inch length (from $x = 2$ to $x = 12$ inches) will be used. The streamwise step size will be 1 inch and the finest transverse step size will be 0.00075 inches.

In addition to turbulent mixing other modes of heat transfer exist. The film-cooled duct of emissivity 0.95 receives radiative heat from an upstream source whose temperature and emissivity are 571.5°R and 1.0, respectively. As well, the duct radiates heat to a cool downstream source possessing a temperature of 530°R and emissivity of 1.0. The radiation shape factors for these energy exchanges are summarized in Table B-I below.

distance from slot exit (inches)	factor from hot upstream source to duct	factor from duct to downstream cold source
1	0.463	0.048
2	0.430	0.051
3	0.398	0.055
4	0.369	0.058
5	0.342	0.062
6	0.316	0.066
7	0.293	0.071
8	0.271	0.076
9	0.251	0.081
10	0.232	0.087

TABLE B-I: Radiation Shape Factors for Sample Problem

A final radiative heat-transfer process is one from the exhaust gas to the duct wall. For these purposes the gas is assumed to have an emissivity of 0.05 and the effective shape factor is considered to be unity. Radiation between neighbouring regions of the duct is ignored.

A sample data deck for this problem appears in Figure B-1. A portion of the output showing results of the iterative solution procedure appears in Figure B-2. These results are illustrated graphically in Figure 8. The example just presented is actually the first slot of the three-slot configuration shown in the figure.

13. ABSTRACT A computer model to calculate the development of wall jet boundary layers downstream of multiple film-cooling slots is described. The differential equations for the conservation of mass, momentum and energy in an incompressible two-dimensional or axisymmetric flow are solved using a downstream-marching, iterative, implicit, finite-difference scheme. The turbulent transport of mass in a conventional wall boundary layer is described by means of an inner-outer two-layer eddy-viscosity model based on the Prandtl mixing-length hypothesis with Van Driest's modification in the near-wall region. Further alterations to include the effects of pressure gradients, heat and mass transfer are due to Cebeci and Smith. This basic model is extended to include cases with tangential fluid injection. Computed velocity profiles indicate that the law of the wall is obeyed in the inner layer and that the outer wake-like layer strives to resume the velocity-defect relationship that existed upstream of the point of fluid injection in zero pressure-gradient flow with no heat or mass transfer. Comparison between computed and experimental adiabatic wall temperature distributions in flows with heat transfer shows that the eddy-viscosity model is deficient in the near-slot region and tends to

KEY WORDS

ABSTRACT (Cont'd)

overestimate film-cooling efficiency. The absence of an eddy term to account for turbulence due to finite slot lip thickness is partly responsible for this overestimation.

Recommendations are made to validate the model in pressure-gradient flows and to improve the predictive capability in the near-slot region.

INSTRUCTIONS

1. **ORIGINATING ACTIVITY:** Enter the name and address of the organization issuing the document.
- 2a. **DOCUMENT SECURITY CLASSIFICATION:** Enter the overall security classification of the document including special warning terms whenever applicable.
- 2b. **GROUP:** Enter security reclassification group number. The three groups are defined in Appendix M of the DRB Security Regulations.
3. **DOCUMENT TITLE:** Enter the complete document title in all capital letters. Titles in all cases should be unclassified. If a sufficiently descriptive title cannot be selected without classification, show title classification with the usual one-capital-letter abbreviation in parentheses immediately following the title.
4. **DESCRIPTIVE NOTES:** Enter the category of document, e.g. technical report, technical note or technical letter. If appropriate, enter the type of document, e.g. interim, progress, summary, annual or final. Give the inclusive dates when a specific reporting period is covered.
5. **AUTHOR(S):** Enter the name(s) of author(s) as shown on or in the document. Enter last name, first name, middle initial. If military, show rank. The name of the principal author is an absolute minimum requirement.
6. **DOCUMENT DATE:** Enter the date (month, year) of Establishment approval for publication of the document.
- 7a. **TOTAL NUMBER OF PAGES:** The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.
- 7b. **NUMBER OF REFERENCES:** Enter the total number of references cited in the document.
- 8a. **PROJECT OR GRANT NUMBER:** If appropriate, enter the applicable research and development project or grant number under which the document was written.
- 8b. **CONTRACT NUMBER:** If appropriate, enter the applicable number under which the document was written.
- 9a. **ORIGINATOR'S DOCUMENT NUMBER(S):** Enter the official document number by which the document will be identified and controlled by the originating activity. This number must be unique to this document.
- 9b. **OTHER DOCUMENT NUMBER(S):** If the document has been assigned any other document numbers (either by the originator or by the sponsor), also enter this number(s).
10. **DISTRIBUTION STATEMENT:** Enter any limitations on further dissemination of the document, other than those imposed by security classification, using standard statements such as:
 - (1) "Qualified requesters may obtain copies of this document from their defence documentation center."
 - (2) "Announcement and dissemination of this document is not authorized without prior approval from originating activity."
11. **SUPPLEMENTARY NOTES:** Use for additional explanatory notes.
12. **SPONSORING ACTIVITY:** Enter the name of the departmental project office or laboratory sponsoring the research and development. Include address.
13. **ABSTRACT:** Enter an abstract giving a brief and factual summary of the document, even though it may also appear elsewhere in the body of the document itself. It is highly desirable that the abstract of classified documents be unclassified. Each paragraph of the abstract shall end with an indication of the security classification of the information in the paragraph (unless the document itself is unclassified) represented as (TS), (S), (C), (R), or (U).

The length of the abstract should be limited to 20 single-spaced standard typewritten lines; 7 1/4 inches long.
14. **KEY WORDS:** Key words are technically meaningful terms or short phrases that characterize a document and could be helpful in cataloging the document. Key words should be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context.
