Abstract.

$H(x)$, the negative logarithm of the apriori probability $M(x)$, is Levin's variant of Kolmogorov's complexity of a natural number x .

Let $\alpha(n)$ be the minimum complexity of a number larger than n ,

$s(n)$ the logarithm of the apriori probability of obtaining a number larger than n . It was known that

$$s(n) \leq \alpha(n) \leq s(n) + H(s(n))$$

We show that the second estimate is in some sense sharp.

September, 1979

Abstract.

$H(x)$, the negative logarithm of the apriori probability $M(x)$,
is Levin's variant of Kolmogorov's complexity of a natural number x .
Let $\alpha(n)$ be the minimum complexity of a number larger than n ,
 $s(n)$ the logarithm of the apriori probability of obtaining a number
larger than n . It was known that

$$s(n) \leq \alpha(n) \leq s(n) + H(\lfloor s(n) \rfloor) .$$

We show that the second estimate is in some sense sharp.

Relation Between the Complexity and the Probability of Large Numbers

Peter Gacs

Let $T(p)$ be a partial recursive function defined over binary sequences with values among the natural numbers which is prefixless:

- (a) If p_1 is a beginning segment of p_2 and $T(p_1)$ is defined then $T(p_2) = T(p_1)$

and optimal:

- (b) for any other prefixless p.r. function T' , there is a sequence p such that $T(pq) = T'(q)$ for all q .

Let $l(p)$ denote the length of the sequence p . Levin introduced the complexity

$$H(x) = \min\{l(p) : T(p) = x\}$$

as a useful variant of Kolmogorov's complexity. See e.g. [1], also Chaitin [2], Gacs [3].

We denote by $T(p;t)$ a computable "approximation" of $T(p)$: on some Turing machine computing $T(p)$, $T(p;t)$ is $T(p)$ if $T(p)$ is computed within time t , undefined otherwise. We write

$$H(x;t) = \min\{l(p) : T(p;t) = x\}$$

$$M(x) = 2^{-H(x)}, \quad M(x;t) = 2^{-H(x;t)},$$

$$s(n) = -\log\left(\sum_{i=n}^{\infty} M(i)\right)$$

$$\alpha(n) = \min_{i \geq n} H(i).$$

$\alpha(n)$ and $s(n)$, two extremely slowly (slower than any unbounded, recursive function) growing functions, are closely related. It is known that

$$(1) \quad s(n) \leq \alpha(n) \leq s(n) + H(\lfloor s(n) \rfloor),$$

where $\leq$ and $\asymp$ denote inequality and equality to within an additive, $\lesssim$ and $\approx$ to within a multiplicative constant.

The first inequality is trivial, the second one is well-known (see e.g. [4]). A hint to the proof: to find a number $\geq n$, we have only to know $2^{-s(0)}$ to within an error term $2^{-s(n)}$.

We will show that the second estimate in (1) is sharp.

Theorem. Let $g(n)$ be any positive, monotone recursive function such that

$$(2) \quad \sum_n 2^{-g(n)} = \infty.$$

Then $\alpha(n) > s(n) + g(s(n))$ infinitely often.

Proof. It is well-known (see e.g. [3]) that, if $\mu(n;t)$ is a computable nonnegative rational function over pairs of natural numbers, monotone in t and $\sum_n \mu(n;t) \leq 1$, i.e., for each t , $\mu(n;t)$ is a semimeasure, then

$$\mu(n;t) \lesssim M(n).$$

Put

$$s(n;t) = \sum_{i \geq n} M(i;t)$$

$$s_\mu(n;t) = \sum_{i \geq n} \mu(i;t)$$

$$m(k;t) = \max\{n: s(n;t) < k\}$$

$$m_{\mu}(b;t) = \max\{n; s_{\mu}(n;t) < k\} .$$

The construction depends on n_k , a fast-growing recursive sequence.

We will see at the end of the proof, how we should choose it in dependence of g .

$$\text{Let } \mu(n;0) = 0 .$$

Suppose that $\mu(n;t)$ is already constructed. Put

$$k(t) = \max\{k \geq -\log(1 - s_{\mu}(0;t)): \exists i \in [n_{k-2}+1, n_{k-1}]\}$$

$$(3) \quad \alpha(m_{\mu}(i - g(i);t);t) > i\} .$$

Put $n(t) = n_{k(t)}$. Let $j(t) = \max\{j: \mu(j;t) > 0\}$. Put

$$\mu(j(t)+1;t) = 2^{-n(t)}$$

$$\mu(j;t+1) = \mu(j;t) \quad \text{for } j \neq j(t) .$$

We will show that there are infinitely many i 's such that for almost all t , (3) holds.

This implies, of course, that

$$\alpha(m_{\mu}(i - g(i)) > i .$$

That is, for some n , with

$$i - g(i) > s_{\mu}(n)$$

$$\alpha(n) > i > s_{\mu}(n) + g(i) \geq s(n) + g(i) \geq s(n) + g(s(n))$$

and the theorem will be proved.

Suppose that, on the contrary, there is a largest i_0 among the i such that (3) holds for almost all t and a least t_0 such that (3) holds for i_0 and all $t \geq t_0$.

Under the above assumptions,

$$s_{\mu}(0;t) \rightarrow 1 .$$

Therefore

$$\sum_t 2^{-n(t)} = 1 .$$

Notation. $A(t_1, t_2) = \sum_{t=t_1}^{t_2} 2^{-n(t)} ;$

$$B(t_1, t_2, k_0) = \sum \{2^{-n(t)} : t \in [t_1, t_2], k(t) = k_0\} .$$

Lemma. There exists a triple (k_0, t_1, t_2) with $k_0 \geq k(t_0)$, $t_2 \geq t_1 \geq t_0$ such that

(a) $k(t) \geq k_0$ for $t \in [t_1, t_2]$;

(b) $2^{-n_{k_0}-1} \leq A(t_1, t_2) \leq 3 B(t_1, t_2, k_0) .$

Proof. For some t^0 , $(k(t_0), t_0, t^0)$ will satisfy (a) and the first inequality of (b).

Let us say that $(k_0, t_1, t_2) \leq (k'_0, t'_1, t'_2)$ if $k'_0 \leq k_0$, $t'_1 \leq t_1 \leq t_2 \leq t'_2$.

Let (k_0, t_1, t_2) be a minimal triple $\leq (k(t_0), t_0, t^0)$, among the triples satisfying (a) and the first part of (b).

(A) For $t_3 \in [t_1, t_2]$ we have $k(t) = k_0$, otherwise the triple is not minimal.

For similar reasons we have

(B) If $t_1 \leq t'_1 \leq t'_2 \leq t_2$ and $k(t) > k_0$ in $[t'_1, t'_2]$ then
then $B(t'_1, t'_2) < 2^{-n_{k_0}}$.

Therefore we have

$$\begin{aligned} A(t_1, t_2) &\leq B(t_1, t_2, k_0) + (1 + \#\{t \in [t_1, t_2]: k(t) = k_0\}) \cdot 2^{-n_{k_0}} \\ &\leq 2B(t_1, t_2, k_0) + 2^{-n_{k_0}}. \quad \square \end{aligned}$$

We concentrate now on a triple $(k, t_1, t_2) \leq (k(t_0), t_0, t_0^0)$ satisfying (a) and (b).

Notation. For $i \in [n_{k-1}, n_k]$ put

$$E_i = \{t \in [t_1, t_2]: \exists n \ H(n; t) \leq i, H(n; t) < H(n; t-1)\}.$$

We now estimate $s_i = \# E_i$ from below (see (5)). Let us write

$$E_i = \{t_{i1}, t_{i2}, \dots, t_{is_i}\}, \text{ where } t_{ij} < t_{ij+1}. \text{ Put } t_{i0} = t_1 - 1,$$

$t_{is_i+1} = t_2$. Let u_{ij} = the last t in $[t_{ij}+1, t_{ij+1}]$ (if any) with $k(t) = k$. If there is no one, $u_{ij} = t_{ij}$.

$$\text{Let } \sigma_{ij} = \sum_{t=t_{ij+1}}^{u_{ij}-1} 2^{-n(t)}, \quad \lambda_{ij} = -\log \sigma_{ij}. \text{ Then by our}$$

algorithm we have

$$\alpha(\mu(i - g(i)); u_{ij}-1) \leq i.$$

On the other hand, by the definition of u_{ij} ,

$$\alpha(j(t_{ij}+1); u_{ij}-1) > i.$$

Therefore we have

$$\lambda_{ij} = s(j(t_{ij}+1); u_{ij}-1) \geq i - g(i),$$

$$(4) \quad \sigma_{ij} \leq 2^{-i+g(i)}.$$

On the other hand,

$$\begin{aligned} 2^{-n_{k-1}} &\leq \sum_{t=t_0}^{t_2} 2^{-n(t)} = \sum_{t \in E_1} 2^{-n(t)} + \sum_j \sigma_{ij} + B(t_1, t_2, k) \\ &\leq s_i \cdot 2^{-n_k} + (s_i + 1) 2^{-i+g(i)} + B(t_1, t_2, k) . \end{aligned}$$

Using (b) of the Lemma,

$$\frac{2}{3} \cdot 2^{-n_{k-1}} \leq (s_i + 1) (2^{-n_k + 2^{-i+g(i)}}) \leq 2(s_i + 1) (2^{-i+g(i)}) .$$

Hence

$$s_i \geq \frac{1}{3} \cdot 2^{-n_{k-1} + i - g(i)} - 1 ,$$

that is, for $i - g(i) > n_{k-1} + 2$:

$$(5) \quad s_i \geq \frac{1}{4} \cdot 2^{-n_{k-1} + i - g(i)} .$$

Put $m_k = \min\{i: i - g(i) > n_{k-1} + 2\}$.

We have

$$\begin{aligned} 1 &\geq s(0; t_2) - s(0; t_1) \geq \sum_{i=m_k+1}^{n_k} 2^{-i} \cdot (s_i - s_{i-1}) + 2^{-m_k} \cdot s_{m_k} \\ &= \sum_{i=m_k}^{n_k} 2^{-i} s_i - \sum_{i=m_k}^{n_k-1} 2^{-i-1} \cdot s_i \\ &\geq \sum_{i=m_k}^{n_k-1} 2^{-i-1} \cdot s_i \geq \frac{1}{8} \cdot 2^{-n_{k-1}} \cdot \sum_{i=m_k}^{n_k} 2^{-g(i)} . \end{aligned}$$

If n_k is chosen far enough from n_{k-1} , this will obviously lead to a contradiction. $\square$
