PREFACE

The Vulnerability Model (VM), a computer model developed by Enviro Control, Inc. for the U.S. Coast Guard, simulates the development of hazardous materials spills and computes the consequences to people and property from resulting fires, explosions, or toxic vapors. It is being developed as a major component of the U.S. Coast Guard Risk Management System for evaluating the cost-benefits of alternate means for reducing the risks and consequences of marine accidents involving hazardous materials. Recently the U.S. Coast Guard has adopted Population Vulnerability Model (PVM) as the official name for the model. This change has not been incorporated in this report and VM is used throughout, a name which is synonymous with PVM.

The VM has undergone a phased development. This report describes the work under the latest phase, which is to prepare the VM for operational use. The work was performed under the overall technical direction of Dr. Michael C. Parnarouskis, the U.S. Coast Guard Project Officer, who must be given credit for the basic operational concepts developed and incorporated in the VM and reported here. Particular mention is made of his role in the design of the User Interface Module (UIM), a valuable addition to the VM which transforms the highly complex VM simulation into an easy-to-use analytical tool.

Acknowledgement is made also of the contribution of Dr. Alan L. Schneider who assisted in selection of the chemicals for simulation and provided data on the characteristics and transportation of hazardous chemicals.

Finally, the efforts of John Remmert and Dr. Chi K. Tsao are gratefully acknowledged. Mr. Remmert programmed the initial version of the Users Interface Module, and Dr. Tsao did much of the work on the displays and contributed substantially to their documentation in Chapter III.

Chapter 1

INTRODUCTION AND SUMMARY

A. INTRODUCTION

This report describes the work performed during the past year to prepare the U.S. Coast Guard Vulnerability Model (VM) for operational use. Four specific tasks were carried out:

- Development of the User Interface Module (UIM), an easy-to-use conversational program which enables inexperienced or occasional users to set up and run VM simulations easily and reliably with little or no training.
- Development of a series of VM output display routines which display the results of VM simulations on CRT terminals or hard copy plotters.
- Development of ready-to-use Geographical/Demographic files for Los Angeles and New York Harbors (a file for New Orleans already exists).
- Performance of a number of VM spill simulations for selected chemicals in Los Angeles and New York Harbors to operationally test the UIM/VM system and to provide a hazard ranking of the selected chemicals.

The accomplishments of the four tasks are summarized in the Summary section of this chapter and are described in detail in the following chapters (Chapters 2 through 5). Appendix A gives a brief description of the Vulnerability Model (VM) for readers unfamiliar with its characteristics and its use. More complete information on the VM is provided in references [1] through [5].

B. SUMMARY

This section presents a brief summary of each of the four study tasks. Following the task summaries is a summary of additional VM program modifications that were made to improve the utility of the VM output tables and to correct VM logic errors that were found during the course of the work.

1. User Interface Module (UIM)

The UIM has been designed and developed to meet general specifications defined by the U.S. Coast Guard. It is a conversational program which interacts with the user to help prepare the inputs and the files needed to run the VM. Although it is a separate program from the VM, it is linked to the VM and all instructions and commands needed to run the VM are provided through the UIM. Instructions and explanatory material are built into the UIM so that the program is essentially self-explanatory and, in general, a user's manual is not needed to use the UIM. An abbreviated version of the file preparation conversation is provided in addition to the detailed instructional version, to enable the more experienced users to run VM simulations in as short a time as possible. Figure 1-1 is a flow diagram of the UIM illustrating its principal features and the key user options.

A key feature of the UIM is its ability to augment the data provided by the user, with information from its internal files, to provide a complete, consistent, and correctly formatted set of inputs for the VM. This internal data is data that is dependent on basic scenario inputs but is particularly difficult for the user to acquire; e.g., flame speeds, probit coefficients. These data have been prepared in advance and placed in the internal UIM Chemical Properties file. The UIM can perform VM simulations only for those chemicals which have been inserted in the UIM and checked out in advance. Currently, there are 27 hazardous chemical property sets incorporated in the UIM (see Table 2-2 in Chapter 2).

To validate its operational effectiveness, the UIM/VM system has been successfully exercised by engineering-oriented personnel with no VM or computer experience. A User's Operational Manual has been published which gives complete instructions on how to access and operate the UIM [6]. Included in the manual is a section which explains and interprets the VM output tables.

The UIM program documentation is provided in Chapter 2 below. This includes the program information needed for maintaining and updating the UIM as required to incorporate additional chemicals or user aids.

FIGURE 1-1. Structure of the UIM

2. Graphical Displays

Graphical routines have been developed to display the major results of the VM simulation on CRT terminals or hard copy plotters. Thirteen specific output displays have been developed, namely:

- Four isoconcentration displays
 - irritation* threshold for puff and plume
 - lower flammability limit for puff and plume
- Four injury** displays
 - toxic injury for puff and plume (outdoors)
 - flash fire and explosion injury
- Four lethality*** displays
 - toxic lethality for puff and plume (outdoors)
 - flash fire and explosion lethality
- One structural damage display

All displays are in the form of isoconcentration or isofractional damage contours overlaid on a schematic map of the geographical cells. Thus, the user obtains a visual accounting of which cells are affected, and to what degree.

An additional feature of the displays is the option of changing spill location, wind direction, or ignition center (where applicable) interactively without having to rerun the VM parametrically. This permits users to economically and rapidly estimate the effect on damage of changes in these parameters.

To incorporate the displays, the VM has been modified with the addition of six new subroutines. At the user's option, the display data are generated during the VM simulation and stored in a VM output file which can be called up and displayed anytime the user desires. Chapter 3 below describes the display routines and their derivations and gives instructions on how to use the displays.

*"Irritation" is a discomforting but nonincapacitating impairment.

**"Injury" is an impairment requiring hospitalization.

***"Lethality" implies immediate and lasting total incapacitation.

3. Geographical/Demographic Files*

A methodology has been developed for generating Geographical/Demographic files to satisfy arbitrary specifications on the number of cells and the general location of the file. The key element of the methodology is a computer program which searches the census MEDList tape and identifies all census block groups that are located within a quadrilateral defined by a central point plus and minus a Δx and a Δy . The user initially inputs the quadrilateral which encompasses the appropriate area he is interested in. He then examines the results and repeats the process with a modified quadrilateral until he obtains the number of cells desired for the file. The maximum size of the Geographical/Demographic file that can be processed by the VM is 400 cells.

To reduce file generation cost and to overcome tape reading problems caused by differences in IBM and CDC software, intermediate MEDList tapes have been created which contain only those portions of the MEDList encompassing the harbor areas of interest. These intermediate files are then searched as described, to create the specific file limited to the particular area and number of cells desired.

Intermediate MEDList files were created for the New York City and Los Angeles areas. Three Geographical/Demographic files, each containing slightly less than 400 cells, were then created for the two cities: one for Los Angeles Harbor (San Pedro/Long Beach and the area immediately north of the harbor) and two for New York Harbor (the Perth Amboy vicinity and the Lower Brooklyn/Coney Island area). Together with the New Orleans Geographical/Demographic file, there are now four ready-made Geographical/Demographic files available for VM users.

Chapter 4 of this document describes in detail the generation and the characteristics of the Geographical/Demographic files.

*The Geographical/Demographic file consists of a file of census block groups or enumeration districts for a given geographical area. For each cell (census block group/enumeration district) in the file, the identifier, latitude and longitude of the cell center, the population, the number of structures within the cell, dollar value per structure, and ignition strength of the cell are specified.

4. Spill Simulations

To check out and test the UIM/VM system and the newly generated Geographical/Demographic files, a number of spill simulations were run for a variety of chemicals and spill scenarios at the New York and Los Angeles Harbors. The purpose of these simulations was twofold. In addition to validating the UIM/VM system, the simulations provide a means of evaluating or ranking the relative hazard potential of a series of hazardous cargoes selected by the U.S. Coast Guard.

The cargoes that were selected for simulation are listed in Table 1-1. These chemicals were chosen in part by an analysis of hazard properties (e.g., toxicity, flammability), and in part by consideration of shipment volumes. For the toxic chemicals, the probit coefficients were derived from an analysis of toxicity and health effects data in the literature, and for all the chemicals, the chemical/physical data needed for the UIM files was prepared and incorporated in the UIM.

Three spill sites were selected (two for New York and one for Los Angeles) and for each a standard environmental scenario was defined which was used for all chemicals. Table 1-2 defines the spill scenarios for each spill site. The only differences in spill simulations between chemicals (other than the chemical properties) was in the cargo characteristics. Tank capacities (and associated temperatures and pressures) were selected for each chemical which correspond to the maximum tank size that is customarily transported by water for that chemical. Table 1-1 gives the tank capacities assumed for each chemical cargo. For all cargoes, the identical rupture characteristics were simulated (hole size and location). Due to the different tank capacities the size of the spill varies with chemical, but the simulations are all consistent in that they represent the maximum amount that can be spilled from a specified type of rupture in a single tank.

The simulations were initially run by experts for the Perth Amboy scenario to check out the UIM/VM system operation. Based on an analysis of the results, errors and problems in the system were found and corrected. Then the simulations for the remaining scenarios were run by novices with a minimum of training and assistance. These latter exercises were completed successfully and demonstrated the operational acceptability of the UIM.

The results of the simulations were carefully analyzed for the purpose of ranking the relative hazards of the 15 chemicals. Table 1-3 summarizes the results of this ranking. The 15 chemicals fall into four hazard categories and seven hazard rankings.

TABLE 1-1
Simulation Scenario Cargo Characteristics

CHEMICAL NAME	CODE	TANK CAPACITY (m ³)	TANK HEIGHT (m)	CARGO PRESSURE ^a (atm)	CARGO TEMPERATURE ^b (°C)	HAZARD ^c
Acetaldehyde	AAD	3,000	15	1 (C)	Ambient	F
Acrylonitrile	ACN	3,000	15	1 (C)	Ambient	T
Ammonia (Anhydrous)	AMA	10,000	20	1 (V)	-33	T
Chlorine	CLX	182	7	1 (V)	-33	T
Dimethylamine	DMA	3,000 ^d	15	2.5 (C)	Ambient	F
Ethyl ether	EET	3,000 ^d	15	1 (C)	Ambient	F
LNG	LNG	25,000	22	1 (V)	-161	F
LPG	LPG	10,000	20	1 (V)	-40	F
Methyl bromide	MTB	3,000	15	1 (C)	4	T
Methyl chloride	MTC	3,000 ^d	17	1 (V)	-24	F
Octane	OAN	4,000	17	1 (C)	Ambient	F
Pentane	PTA	4,000	17	1 (C)	Ambient	F
Propylene oxide	POX	3,000	15	1 (C)	Ambient	T, F
Toluene	TOL	4,000	17	1 (C)	Ambient	T
Vinyl chloride	VCM	6,000	17	1 (V)	-14	F

For all chemicals: fraction filled = 0.98
hole diameter = 2 m
height of centerline above waterline = 1 m
height of hole bottom above tank bottom = 0

^a (C) = closed tank; (V) = vented tank

^b Ambient = sea temperature

^c F = flash fire; T = toxic

^d Double tank capacity (6,000 m³) was also simulated for these three cases.

TABLE 1-2
Simulation Scenario Site Characteristics

SPILL SITE	SPILL LATITUDE (N)	SPILL LONGITUDE (W)	WIND DIRECTION	STABILITY COEFFICIENT	AIR TEMPERATURE	WATER TEMPERATURE	GEOGRAPHIC FILE NO.
New York Harbor (Perth Amboy)	40°30'40"	74°15'35"	315°	P	28°C	22°C	3611
New York Harbor (Coney Island)	40°31'25"	74°00'00"	5°	D	28°C	22°C	3612
Los Angeles Harbor (Long Beach)	33°42'34"	118°16'19"	0°	D	24°C	20°C	1611

For all spills: open waters
spill-to-shore separation = 300 meters
wind speed = 4 m/s (Perth Amboy runs: 2 m/s)
population sheltered = 0.50

TABLE 1-3
Results of Hazard Ranking

HAZARD CATEGORY	DESCRIPTION OF CATEGORY	CHEMICAL	HAZARD RANKING
Most Hazardous	Many thousands of casualties for all scenarios	Chlorine	1
Very Hazardous	Appreciable casualties for all scenarios	LNG	2
		LPG	2
		Methyl Bromide	2
Hazardous	Casualties only under extreme conditions (high atmospheric stability and close-in spills)	Ammonia	3
		Vinyl Chloride	4
		Pentane	4
		Methyl Chloride	5
		Toluene	5
		Ethyl Ether	6
Relatively Nonhazardous	No casualties or damage under any of the scenarios	Octane	7
		Dimethylamine	7
		Acetaldehyde	7
		Acrylonitrile	7
		Propylene Oxide	7

Chlorine is by far the most casualty-producing under all scenario conditions, even though it had the least quantity spilled. LNG, LPG and methyl bromide are ranked next, and no appreciable difference could be distinguished between them. The next six chemicals produced casualties only for one of the three scenarios. This was the scenario of highest atmospheric stability (F) and of closest-in spill (400 meters to closest downwind population cell). These six chemicals are ranked as shown based on the number of casualties. Finally, five chemicals produced no casualties under any conditions and were ranked as relatively nonhazardous. Of these, all are highly soluble except for octane, which is of low volatility.

Several observations are evident from an examination of the simulation results:

- As might be expected, soluble chemicals generally do not result in any casualties or damage. The spilled material rapidly goes into solution which reduces the vapor concentration at downwind cells below hazardous levels for both toxic and flammable materials. An exception to this is ammonia which is highly volatile and which was spilled in a relatively large quantity (10,000 m³).
- For insoluble chemicals, the most hazardous are those that are highly volatile.
- The insoluble chemicals having the lower volatilities resulted in casualties only at Perth Amboy. This was due to the higher atmospheric stability (class F vs. class D) and the shorter distance between the population and the spill site at Perth Amboy versus the Coney Island or Los Angeles scenarios.
- For the most hazardous chemicals, the Coney Island scenario resulted in the most casualties. This was due primarily to the higher population density in the Coney Island area relative to the other two areas.

The spill simulations and their results are fully described and discussed in Chapter 5.

5. Additional VM Program Modifications

In the process of performing the four tasks summarized above, a number of imperfections and errors in the VM program were found and corrected. Of particular importance was the cleanup and clarification of the VM output tables to make the tables more understandable and easy to interpret for the UIM user. Also of major importance was the correction of a number of logic errors that were discovered during the running of the simulations in Task 4.

Listed below are the major cosmetic and logic modifications that were made to the VM program during the performance of the contract. All of these modifications have been incorporated in the latest version of the VM (i.e., cycle 15) which is available through SCOPE disk or on tape. See Chapter 6 for information on accessing the VM program.

a. Modifications to VM output tables

- (1) Suppressed the "loader map" printout that precedes the VM output tables.
- (2) Removed the time-incremented "radiation flux" tables that have not been used since the modification of the flash fire model.
- (3) Provided for optional suppression of the vapor cloud concentration tables in ppm units. These tables are redundant since the concentration is also given in kg/m^3 units.
- (4) Suppressed the ignition output table for toxic runs (the data are meaningless for toxic simulations).
- (5) Printed the cloud dispersion coefficients, σ_y and σ_z , for plume as well as puff runs in the ignition output tables.
- (6) Suppressed all damage tables for cells in which the values were all zero. For large Geographical files of the order of 400 cells, this reduces significantly the time and amount of computer printout.

b. Logic corrections to the VM program

- (1) Corrected an error in the inside dosage computation. The dosage was originally given in ppm-sec and was corrected to ppm-min.
- (2) Corrected an error in air temperature variable which was caused by mistyping of the variable's symbol.

- (3) Corrected an error in the flash fire model that had resulted in the miscomputation of the size of the fireball due to use of incorrect vapor density.
- (4) Revised the flash fire model to improve the accuracy by calling for the input of both the surface flame temperature and the flame speed.
- (5) Corrected errors in the secondary fires flag assignment logic which caused the aborting of certain VM output tables under certain file status conditions.
- (6) Corrected the logic error in subroutine PATH which assigned an incorrect model to some immiscible chemicals (such as ether).
- (7) Revised the venting model to reduce the possibility of computational error (numerical overflow) under adiabatic tank conditions.
- (8) Incorporated a bypass option which enables the user to circumvent the venting, spreading, and evaporation subroutines and go directly to the air dispersion model, Model C. This option supersedes the Path Override option when it is selected.
- (9) Modified the integration time for toxic damage to the lesser of the total evaporation time or the user input "time the computations are to be made", VM field numbers 6001, 6004, or 6007. This enables the user to specify an evacuation time through specification of the time sequence variables. This is particularly important for chemicals with low volatility which take many hours or days to evaporate.

Chapter 2

USER INTERFACE MODULE

A. INTRODUCTION

The User Interface Module (UIM) is a computer program specifically designed for use by personnel with little or no computer experience. By interacting with the user in an easy-to-understand conversational mode, the UIM helps the user set up spill problems for the Vulnerability Model (VM) and then automatically runs the VM to simulate the spills. The UIM feeds data to and controls the VM, and serves as the interface between the VM and the user. In this capacity, the UIM performs six specific functions which assist the user in performing VM simulations.

First, using conversational prompts, the UIM acquires the inputs from the user that are needed to simulate the spill problem he is interested in. It only asks for those inputs that are necessary, thereby relieving the user of the worry about inputs that are not needed or that come from internal UIM or VM files. Approximately 150 inputs are needed for a VM simulation, but for a typical spill problem the user needs to supply only 30 or 40. Table 2-1 is a listing of all the inputs that the UIM requests of the user. In any given problem, a portion of these inputs would not be needed.

Second, the UIM provides information and instructional material that helps the user prepare the input values. Sufficient information is displayed to enable the user to prepare a simulation without the need for supporting documents or worksheets. This information is displayed only when requested by the user, so the experienced user is not held up by information statements he does not need.

Third, the UIM edits the inputs to check for alpha or numeric errors and then informs the user of the type of error.

Fourth, the UIM makes conversions, performs calculations, and provides data from its internal files necessary to complete the VM Input file. This file is then formatted in the proper VM computer format for submission to the VM. Actual submission of the run is made by the UIM following a user-supplied command to do so.

Fifth, the UIM informs the user of the chemicals for which spill simulations can be run, and the ports for which Geographical/Demographic files exist. Spill problems involving these chemicals and ports are the only problems that can be run through the UIM. Tables 2-2 and 2-3 present the chemicals and geographical files available in the UIM as of this writing. A current up-to-date listing of the available chemicals and ports is contained in the UIM program itself and in the UIM User's Operational Manual [6]. (If other chemicals or ports are desired, then either the UIM must be modified to include the proper data or the VM must be operated directly, i.e., not through the UIM.)

TABLE 2-1

Listing of User Inputs to UIM

INPUT NUMBER	INPUT VARIABLE	VALID ENTRIES
1	CHEMICAL CODE	AAD, ARL, ACN, AMA, BUT, BTN, CBT, CLX, DMA, EET, HDC, HCN, HFX, HDS, LNG, LPG, MTB, MTC, OAN, PTA, PHG, PRP, PPL, POX, SFD, TOL, VCM
2	CARGO TEMPERATURE	-200 to +300°C (-432 to +508°F)
3	TANK PRESSURE	(ATMOSPHERES)
4	TANK CAPACITY	(CUBIC METERS or THOUSANDS OF GALLONS)
5 ^a	TANK HEIGHT	(METERS or FEET)
6	FRACTION OF TANK FILLED	0 to 1.00
7	HOLE DIAMETER	Must be >0 (METERS or FEET)
8 ^b	HEIGHT OF CENTERLINE	(METERS or FEET)
9 ^c	HEIGHT OF HOLE BOTTOM	(METERS or FEET)
10	SPILL LOCATION	1 (OPEN or STILL WATERS); 2 (FLOWING WATERS)
11	WATER TEMPERATURE	-4 to +49°C (25 to 120°F)
12 ^d	CHANNEL WIDTH	(METERS or FEET)
13 ^d	AVERAGE RIVER DEPTH	(METERS or FEET)
14 ^d	AVERAGE RIVER VELOCITY	(METERS PER SECOND or FEET PER SECOND)
15 ^d	TYPE OF RIVER BANKS	1 (CLEAN, SMOOTH); 2 (MODERATELY ROUGH); 3 (COARSE, DENSELY VEGETATED)
16	AVERAGE WIND SPEED	(METERS PER SECOND or FEET PER SECOND)
17	WIND DIRECTION	0 to 359 DEGREES
18	AIR TEMPERATURE	-40 to +49°C (-40 to +120°F)
19	ATMOSPHERIC STABILITY CODE	B (UNSTABLE); D (MODERATELY STABLE); F (STABLE)
20	DEGREES LATITUDE	00°00'00" to 89°59'59"
21	DEGREES LONGITUDE	00°00'00" to 179°59'59"

New York, Coney Island area	GEONY6	3612
New Orleans	GEON01	2211
Los Angeles	GEOLA1	1611

Sixth, the UIM provides for storage of previous VM Input files prepared by the user. When similar problems are to be run, the user can call for these files and make changes to them rather than create entirely new files; this greatly reduces the file preparation time.

B. DESCRIPTION OF THE UIM

1. Introduction

In structure, the UIM consists of two programs: (1) UIML, an unabridged program which accommodates the beginner or occasional user, and (2) UIMS, an abridged program which accommodates experienced users who are more conversant with computers and who are sufficiently conversant with the data needs of the VM so as not to need detailed information on the inputs.

Each of the programs is further divided into two branches: a branch for creating a new Input file and a branch for using an Input file previously created and saved. The latter branch is a time-saver when the user is interested in running a series of similarly structured problems which differ in only one or two parameters. An edit routine enables the user to make changes to any of the inputs in the old file and resubmit the run. Figure 1-1 in the Introduction and Summary Chapter 1 illustrates the basic structure of the UIM and a detailed UIM flowchart is presented in Appendix B.

2. Unabridged Program (Detailed or Long Version)

In operation, the user of the UIM is asked initially for his/her name. This is for file-management purposes. Then, the user is asked whether or not he wants to use the unabridged (long) version of the UIM; if the response is negative, the abridged program is then accessed. The differences between the two programs consist of quantity of prose and additional information options. In the long version, each needed data input is explained prior to the actual request for the input value. The input requests are arranged by groups, and there is a preamble to each group, wherein the user is asked whether or not further information is desired. If the response is affirmative, then several paragraphs of additional explanatory material, usually consisting of "typical values" lists or a fuller description of the physical nature of the group of inputs, are presented. This explanatory material is presented in Appendix B of the UIM User's Operational Manual.

3. Abridged Program (Short Version)

The short version was created to satisfy the needs of a more experienced user, who perhaps has resorted to the detailed version several times previously and is sufficiently conversant with the data input explanations so as to not wish to be presented with the textual material each time a file needs to be built. The short version consists of a series of brief, one-line prompts for data, with the cursor (or printhead) remaining on the

line of the prompt each time. No access to the informational passages is granted, and at no time may the user switch back to the detailed version without stopping the program and then restarting (and vice versa).

4. Internal Error Checks

Each version makes the same data range checks for file integrity. If a certain alphabetic response is solicited, it must be entered or the solicitation will be repeated until a satisfactory answer is received. Numeric data must conform to any physical constraints; for instance, latitude(longitude) data must be not greater than 89(179) degrees, 59 minutes, 59 seconds. However, most of the numeric inputs are selectable at the discretion of the user, with no range checks performed.

Certain errors made in inputs when under control of the abridged version will produce error messages that come from the detailed version, but generally only the message "ERRONEOUS INPUT" will be printed. The detailed version will generally present explanations as to the nature of the error and a lengthier request for reentry of the datum.

Each version is structured so as to solicit values only for pertinent inputs. For instance, if a toxic run is requested, the input requesting secondary fires choice will be suppressed. Thus the full set of possible solicitations may not be presented depending upon the spill scenario contemplated by the user.

5. Listing and Naming of Input File

Both programs of the UIM flow identically after the last possible input has been entered. A listing of the file created by the user is presented* with its internally generated name, using the units of measurement specified by the user.

6. Use of Old Input Files

As mentioned previously, the user does not have to create a file each time by answering all of the possible questions sequentially. If a previously UIM-created file exists on disk in the account, and if only a few changes need to be made to it to create a file for a new problem for the VM, the user may opt to reenter this file automatically and save some time and effort in the process.

Immediately after selecting the UIM version desired, the user is asked whether an old or a new file is to be built. If the response is "NEW", sequential input solicitation, starting with the type of measurement units, is initiated as described above. However, if the user selects "OLD", the

*The short version program provides the user the option to view the inputs or to skip the listing and go directly to the editing branch, whereas the long version automatically presents the listing.

program then asks for the name of the old file to be loaded in. The user enters the correct six-character UIM file name, and the program then pulls the file off the disk and loads it. The result of a successful loading is the same as that for completion of the "new file" branch—a listing of the complete file by input.

7. Changes to an Input File (Editing an Input File)

After the listing is completed, the user is asked if any changes (edits) are to be made to the file. If an affirmative response is received, the program then prompts for the line number of the input sought to be changed (from the listing), and then a prompt for the new value is issued. If the detailed program was previously selected, a full prompt is given, and the option for the information statement pertinent to the input is given. The short version presents a brief prompt, with no choice for additional information.

The editing branch is complete in the sense that, if a chain of dependent data values has one of its inputs modified, all of the other values that will be affected will automatically be processed properly. For instance, if the user has a file loaded in with information on river velocity, depth and width, and during editing decides to change the spill environment to a nonriver (open water) scenario, the inputs pertinent to the original river scenario will also be taken out of the edited version. If the opposite situation occurs, the user will be asked for data needed to complete the river scenario automatically before edit control is returned to the user.

8. Completion of the Input File

The user is prompted for more changes after each successful edit. At this time, an entry of the word "LIST" will generate the updated, most current version of the original file's contents. If the user wishes to depart from the edit phase of the program, a negative response to the solicitation for more changes must be entered.

9. Readyng the Input File for VM Simulation

The next question asked will be whether the user wishes to run a VM simulation using the current file. If the response is affirmative, the current file will be arranged internally to fit the format requirements of the VM and a temporary file will be generated; otherwise, no temporary file will be made and the VM will not be run.

10. Saving an Input File

Finally, the user is asked if the current file is to be saved on disk. Automatic storage is not a feature of this program so as not to create a disk-cluttering situation. However, this solicitation has to be used carefully. If the user were to have loaded an old file in and made no changes

to it, then it would be pointless to resave it since old files are always returned unchanged to disk after each run of the program, so the UIM will not honor this request in this situation. However, if the old file was modified, the current file (old file plus modifications) will be saved if so desired. If the file was built from scratch (a new file), it will similarly be saved if so desired.

11. Terminating the UIM and Executing the VM Simulation

If a VM simulation based upon the current file is desired, i.e., if an affirmative response to the UIM query for running the VM is entered, a flag will be set and automatic engagement of the VM submission job stream will occur, with about a 20-second delay before the name of the job is printed. If no simulation is desired, the program will simply terminate and clear all local files from the workspace.

12. Recalling the UIM Program To Prepare Another Input File

After the UIM program terminates, the user may call it back by simply typing in the command "-RUIM" again and starting over. If the generated file was not saved, it will not be retrievable; if it has been saved, then the user may operate on it or any other UIM-saved file at his discretion.

C. UIM PROGRAM DOCUMENTATION

1. General

In this section, the infrastructure is described for the benefit of those wishing to understand the programming logic. Also, the procedure files and jobstreams which are linked to the UIM are described.

2. The UIM Programs

The UIM is actually two similarly constructed programs. The short version is named UIMS; the long version is UIML. It is written in CDC's version of BASIC under NOS, and is retrieved from disk before execution to the user's workspace. The following is a technical description of the common programming philosophy used to construct the modules.

All user entries and applicable internally stored data are arranged in the Z matrix, which is set up in a row-by-column fashion as $Z(a,b)$ where "a" corresponds to the form of data per data entry "b". Specifically, if $a=1$, $Z(a,b)$ will be the VM field identification number for the variable corresponding to b; if $a=2$, $Z(a,b)$ will be the actual (raw) user input, in

alphabetic form, or if numeric, in MKS or British units; if a=3, Z(a,b) will be the converted user input value, i.e., the numeric value converted to the VM-required cgs (centimeter-gram-second) units system.

The major data block stored in the UIM is the C3(a,b) chemical properties matrix, which holds 18 different chemical properties per chemical for 27 chemicals. The chemical properties are those needed for simulation but not retrievable from the master Chemical Properties file accessed by the VM. The chemical code itself is the basis for setting the value of "a" in the C3 matrix; "a" is determined by a short lookup routine that checks to be sure that the three-letter code is one for which the UIM can provide chemical properties.

The program has been wrapped around itself as much as possible to reduce excessive coding by usage of a set of flags that control program flow. The flags are as follows:

- F1 — units flag; 1=British system, 2=MKS system
- F2 — chemical code flag; 0=invalid, 1=valid
- F4 — editing branch flag; 0=editing branch not in use, 1=editing branch in use
- F5 — file type flag; 0=new file, 1=old file
- F6 — version type flag; 0=detailed(long), 1=abridged(short)
- F8 — call to filename generator flag; 0=no call has been made, 1=call has been made (and a name has been generated)
- G4 — geographical file code validation flag; 0=invalid geographic file code (query for a new one), 1=valid code (pull the file off of disk)
- B3 — time sequences source flag; 0=time sequences have been calculated by program, 1=time sequences were supplied by user.

There are several string variable names used by the UIM; the key ones are listed below:

- A1\$ — stores the 26 letters of the alphabet
- A2\$ — temporary location of randomly generated six-letter filename
- A3\$ — stores the valid three-letter chemical codes as a string
- B3\$ — stores the YES/NO response to solicitation to change the internally calculated time sequences (if any)
- D1\$ — command string variable for communicating with NOS
- D\$ — holds the name of the file currently being operated on
- E\$ — variable to which the name of an old file is passed if if the user opts to save the edited version of the old file (on disk)

- F\$ — holds name of geographical file stored on disk corresponding to the input geographical file code
- G\$ — holds name of the corresponding (to F\$) secondary fires file if it exists and if a secondary fires run is requested by the user
- K\$ — controls flow pertinent to whether a detailed or abridged version run is requested
- L1\$ through L7\$ — hold latitude (L1\$ & L2\$ & L3\$ & L7\$) and longitude (L4\$ & L5\$ & L6\$ & L7\$) substring values broken down by degrees, minutes, seconds, and decimal
- L\$(1), L\$(2) — concatenated substrings from Ln\$ series for latitude and longitude, as DDDMMSS.
- M1\$ — holds the valid three-letter chemical code
- M5\$ — holds YES/NO response to prompt for consideration of secondary fires sources; used with G\$ to produce a disk-retrieval command if appropriate
- M9\$ — stores the selected atmospheric stability code
- U\$ — stores the file source (old or new)
- W\$ — general alphanumeric input variable
- Y2\$ — holds YES/NO response to prompt to run a VM simulation.

There are four levels of file status permissible in the UIM. Level 1 is for a new UIM file; Level 2 is for an old UIM file; Level 3 is for an edited old UIM file; and Level 4 is for the VM input file (VMINPUT). Figure 2-1 on page 2-10 lists a typical disk-saved UIM-created file that could have been produced out of Levels 1, 2, or 3, given the randomly generated name APAPAP. For comparison, Figure 2-2 on page 2-11 lists APAPAP in the VM-ready form, the Level 4 file VMINPUT. Functions specific to CDC BASIC that are used include RND (produce a random number from zero to one), DAT\$ (produce the date), FILE (control file disposition), CLOSE (similar to FILE), GET and SAVE (NOS commands).

The VM field numbers, associated variable descriptions, and corresponding Z matrix second-subscript values are presented in Table 2-4 on pages 2-12 and 2-13.

*These inputs are also computed by the UIM and will be used if the user so chooses.

3. UIM-Associated Files and Jobstreams

The UIM is accessed either directly or by recourse to a procedure file named RUIM ("Run-UIM") which automatically selects the user-desired UIM version, and then tests for the possible UIM file outputs to set up and run a VM submission. Usage of RUIM is recommended for routine runs of the VM; it is not useful when display plot files are desired (since the UIM does not set KPLOT), when bypass or ppm table suppression runs are contemplated, or when updates are to be included in a VM run, unless modifications to the called jobstreams are also made. RUIM is presented as Figure 2-3. Note that it is set up to call either of two jobstreams, RUNUIM or RUNUIM2, and that it clears all files from the workspace after a successful submission, thus allowing for multiple runs during a single session.

RUIM initially calls UCLECT, a short procedure file which retrieves from disk the version of the UIM corresponding to the user's input to a YES or NO solicitation. At present, the UIM long version is not storable as an object module due to its great length, so it must be compiled each time it is used. A compilation plus execution of UIML generally requires about 12 SBU's of system resources, which is \$5.40 under current rates (the short version generally requires 7.5 SBU's or \$3.38).

RUIM eventually calls jobstream RUNUIM (if a secondary fires run is to be performed) or RUNUIM2 (in the opposite case). RUIM, UCLECT, RUNUIM, and RUNUIM2 are listed as Figures 2-3 through 2-6. The flowchart for the UIM programs as they are embedded in RUIM is presented in Appendix B along with a listing of the respective source codes.

D. DATA PREPARATION FOR UIM CHEMICAL PROPERTIES FILE

As previously mentioned, the major data block stored in the UIM is the Chemical Properties file which holds 18 different properties for each chemical, of which there are currently 27. These properties are those needed for VM simulation but not retrievable from the VM Chemical Properties file.

Table 2-5 presents the data currently contained in the file for the 27 chemicals. These data were obtained through a literature search or consultation with experts. As noted, some data were unavailable and default values are being used until data can be developed.

The probit coefficients for toxic chemicals are a key part of the UIM Chemical Properties file. Appendix C discusses the derivation of the probit coefficients for all of the toxic chemicals, including the checking and correction of the coefficients for probits previously derived.

(h) Assumed values used in lieu of actual values until they become available.

E. USER DOCUMENTATION

Instructions for using the UIM are provided in the UIM User's Operational Manual [6]. This manual describes the function and structure of the UIM, presents basic operating instructions, gives examples of UIM operating sessions, and describes and interprets the VM output.

Chapter 3

VM GRAPHICAL DISPLAYS

A. INTRODUCTION

To enhance the utility of the VM simulations, a series of graphical displays have been developed which display on a CRT terminal or plotter the extent of the personnel and structural damage associated with toxic, flammable, or explosive chemical spills. By use of the graphical displays, the spatial and temporal characteristics of the hazards become more readily comprehensible, and the analyst is provided with a more descriptive summary of the progress of the hazardous event.

The set of display plots (frames) that have been developed for a particular spill simulation consists of:

- A family of curves showing the constant concentration contour lines for the atmospheric transport of a hazardous vapor, based on lower ignitable limit or irritation threshold.
- Zones of expected fatalities, disaggregated by fractional damage contours.
- Zones of expected injuries, disaggregated by fractional damage contours.
- Zones of structural damage.

The contour lines are superimposed over a schematic map of the corresponding cell (vulnerable resource) centers to further clarify the VM results.

Currently the plots can be displayed on Tektronix-type CRT terminals (Models 4010 or 4012) or plotted on CALCOMP hard copy plotters. Construction of the VM plotting package has been performed in a modular fashion, and the particular procedure files that inform the computer of terminal status can be easily rearranged to accommodate different brands of CRT terminals or hard copy plotters.

When using the interactive display programs, the user is granted the option to alter some of the original scenario features, such as wind direction and spill location, as a means of analysing the same basic problem parametrically without going to the expense of further VM runs.

All of the plotting data is generated by the VM, which has been modified and to which seven new subroutines have been added. The generated plotting data are stored on a disk file. X,y plotting data are generated for the following variables:

- irritation threshold vapor concentration--puff model
- irritation threshold vapor concentration--plume model
- lower flammability limit vapor concentration--puff model
- lower flammability limit vapor concentration--plume model
- lethality from toxicity, outdoors--puff model
- lethality from toxicity, outdoors--plume model

- nonlethal toxic injury, outdoors—puff model
- nonlethal toxic injury, outdoors—plume model
- lethality from flash fire
- nonlethal injury from flash fire
- lethality from explosion peak overpressure
- nonlethal injury from overpressure
- structural damage

All data are displayed on a display which shows the spill site and the relevant cell centers. For the irritation threshold and the lower flammability limit associated with the puff model (variables 1 and 3), x,y contours are generated as a function of time (i.e., for a progression of time steps) so the user can see how the puff progresses with time. For all the remaining variables, time-independent envelopes are generated which show the regions affected. For all the lethality variables and for the structural damage variable, each display consists of several envelopes corresponding to several levels of lethality or damage presented as percent deaths or percent buildings destroyed.

All the plotting data generated in the VM are stored in a direct-access disk file which is saved under a system-given name. The user can retrieve the data for plotting using this name.

Three programs for plotting have been written which are independent of the VM. The program TOXDISP displays all curves relevant to toxic casualties; program FIRDISP displays all curves relevant to fire casualties; program EXPDISP displays all curves relevant to explosion casualties.

B. DERIVATIONS

The data generated are based upon the equations derived in the previous VM reports [1-5]. These equations are:

- vapor dispersion equations (3-1) and (3-2) (ref. [1])
- explosion equations (4-4) to (4-6) (ref. [1])
- flash fire equation (4-15) (ref. [5])
- toxic dose equations (2-6) and (2-7) (ref. [5])
- probit equation (6-1) (ref. [1])

These equations are rearranged to express the dependent variable y in terms of x as:

$$y = f(x) \quad (3-1)$$

Note that the vapor dispersion coefficients are functions of x only. The details of the derivations are presented in the following subsections entitled:

- Constant Vapor Concentration Contour
- Constant Toxic Casualty Contour, Outdoors
- Thermal Damage from Flash Fire Model
- Damage from Explosion

1. Constant Vapor Concentration Contour

(a) Puff Model

For the puff model, the vapor concentration at some point (x, y, z) at time t is given by:

$$C = \frac{2N}{(2\pi)^{3/2} \sigma_x \sigma_y \sigma_z} \exp \left[-\frac{(x - Ut)^2}{2\sigma_x^2} - \frac{y^2}{2\sigma_y^2} - \frac{z^2}{2\sigma_z^2} \right] \quad (3-2)$$

where:

C = vapor concentration (kg/m^3)

$\sigma_x, \sigma_y, \sigma_z$ = dispersion coefficients in x -, y -, z -directions (m)

N = mass of vapor liberated (kg)

U = wind speed (m/s)

x, y, z = Cartesian coordinates with the origin at the source of the air dispersion material; the wind is assumed to blow toward the positive x -direction, and the crosswind coordinate is y .

When the vapor concentration C is equal to a given value C_L , then equation (3-2) can be written as:

$$\frac{(x - Ut)^2}{\sigma_x^2} + \frac{y^2}{\sigma_y^2} + \frac{z^2}{\sigma_z^2} = 2 \ln \left[\frac{2N}{(2\pi)^{3/2} \sigma_x \sigma_y \sigma_z C_L} \right] \quad (3-3)$$

In this problem, the C_L will be either the lower flammability limit for flammable gases or the lower threshold value for toxic gases. Equation (3-3) gives the constant vapor concentration surface which is an ellipsoid with the center at $(x = Ut, y = 0, z = 0)$. When considering the effects at ground level, $z = 0$ and the contour becomes an ellipse which is:

$$\frac{(x - Ut)^2}{\sigma_x^2} + \frac{y^2}{\sigma_y^2} = 2 \ln \left[\frac{2N}{(2\pi)^{3/2} \sigma_x \sigma_y C_L} \right] \quad (3-4)$$

(b) Plume Model

The plume vapor concentration is given by:

$$C = \frac{2q}{(2\pi)U\sigma_y\sigma_z} \exp \left[-\frac{y^2}{2\sigma_y^2} - \frac{z^2}{2\sigma_z^2} \right] \quad (3-5)$$

where:

q = rate of vapor liberated (kg/s)

With a given concentration C_L , equation (3-5) becomes:

$$\frac{y^2}{\sigma_y^2} + \frac{z^2}{\sigma_z^2} = 2 \ln \left[\frac{2q}{2\pi U \sigma_y \sigma_z C_L} \right] \quad (3-6)$$

Since σ_y and σ_z are functions of x , the surface is like an elongated ellipsoid. On the ground $z=0$, so we have:

$$y^2 = 2\sigma_y^2 \ln \left[\frac{2q}{2\pi U \sigma_y \sigma_z C_L} \right] \quad (3-7)$$

2. Constant Toxic Casualty Contour, Outdoors

In the VM the damage to personnel from toxicity, burn, and explosion is assessed by the probit equation which is defined as:

$$Pr = a + b \ln v \quad (3-8)$$

where v is the dosage, and the coefficients a and b are determined from existing experimental data. The variable Pr is referred to as a probit (probability unit). It is a Gaussian-distributed random variable with a mean value of 5 and a variance of 1. The percent of the vulnerable resources affected is the percent corresponding to the cumulative distribution of Pr . For a given probit Pr , the dosage is:

$$v = \exp \left(\frac{Pr - a}{b} \right) \quad (3-9)$$

The dosage v depends upon both the duration of exposure and the vapor concentration. The general form is:

$$v = \int_0^\infty C^n dt \quad (3-10)$$

where the exponent n is a real number.

(a) Puff Model

The toxic dosage for the puff model is obtained by substituting equation (3-2) into equation (3-10) and integrating over time. The resulting equation is:

$$v = \left(\frac{2M}{(2\pi)^{3/2} \sigma_x \sigma_y \sigma_z} \right)^n \left(\frac{\pi}{2n} \right)^{1/2} \frac{\sigma_x}{U} \left[1 + \operatorname{erf} \left(\sqrt{\frac{n}{2}} \frac{x}{\sigma_x} \right) \right] \exp \left[-\frac{n}{2} \left(\frac{y^2}{\sigma_y^2} + \frac{z^2}{\sigma_z^2} \right) \right] \quad (3-11)$$

where erf is the error function. For a given v and $z=0$, we have:

$$y^2 = \frac{2\sigma_y^2}{n} \ln \left\{ \left(\frac{2M}{(2\pi)^{3/2} \sigma_x \sigma_y \sigma_z} \right)^n \left(\frac{\pi}{2n} \right)^{1/2} \frac{\sigma_x}{vU} \left[1 + \operatorname{erf} \left(\sqrt{\frac{n}{2}} \frac{x}{\sigma_x} \right) \right] \right\} \quad (3-12)$$

The dispersion coefficients ($\sigma_x, \sigma_y, \sigma_z$) increase monotonically with x so that at a certain distance the argument of the logarithm will be unity or y will approach zero. So the contour is a closed curve. Five curves corresponding to 1%, 25%, 50%, 75% and 99% casualties are calculated. The probits corresponding to these percentages are 2.67, 4.33, 5.0, 5.67 and 8.09.

(b) Plume Model

The dose equation for the plume model is:

$$v = \left(\frac{2q}{2\pi U \sigma_y \sigma_z} \right)^n t_e \exp \left[-\frac{n}{2} \left(\frac{y^2}{\sigma_y^2} + \frac{z^2}{\sigma_z^2} \right) \right] \quad (3-13)$$

where t_e is the total evaporation time. In the same manner as in (a) above, for $z=0$ we have:

$$y^2 = \frac{2\sigma_y^2}{n} \ln \left[\frac{t_e}{v} \left(\frac{2q}{2\pi U \sigma_y \sigma_z} \right)^n \right] \quad (3-14)$$

Also, five curves of percent of casualties are calculated as in (a) above.

3. Thermal Damage from Flash Fire Model

The general dose equation for thermal damage is:

$$v = \int I^n dt \quad (3-15)$$

where I is the radiation intensity (J/m^2-s) and n is a real number. The flash fire model is divided into two phases: burning phase and cooling phase. The burning phase starts from the ignition and stops when the fuel is burned out. The cooling phase is the period when the hot vapor cools down to ambient or near-ambient temperature. For personnel damage, only radiation from the burning phase is considered [5].

The thermal dosage for flash fire in the burning phase is given by:

$$v = \frac{3}{11} \frac{1}{S} \left(\alpha \epsilon \sigma T_f^4 \right)^{4/3} \left(\frac{r_b}{d} \right)^{8/3} r_b \quad (3-16)$$

where:

- S = flame velocity (m/s)
- T_f = flame temperature ($^{\circ}K$)
- r_b = fireball radius (m)
- d = distance from the fire center (m)
- α = absorptivity
- ϵ = emissivity
- σ = Stefan-Boltzmann constant ($J/m^2-s-^{\circ}K^4$)

The fireball radius is equal to:

$$r_b = \left(\frac{3 M_0 T_f}{4 \pi \rho_{p0} T_0} \right)^{1/3} \quad (3-17)$$

where:

- M_0 = vapor mass burned (kg)
- ρ_{p0} = density of products at ambient temperature (kg/m^3)
- T_0 = ambient temperature ($^{\circ}K$)

Equation (3-16) can also be written as:

$$d = \left(\frac{3}{11} \frac{1}{vS} \right)^{3/8} \left(\alpha \epsilon \sigma T_f^4 \right)^{1/2} r_b^{11/8} \quad (3-18)$$

When the dosage v is given, the corresponding distance from the fire center d is determined.

4. Damage from Explosion

Explosion casualty is caused by either the peak overpressure or the impulse from the explosion.* The dosage v in the probit equation is, therefore, the overpressure P (N/m²) or the impulse I (N-s/m²).

The energy yield in a gas explosion is described by the following equation:

$$W = (-\Delta H) \frac{M_e}{M} \quad (\text{Kcal}) \quad (3-19)$$

where:

ΔH = heat of combustion (Kcal/kg-mol)

M_e = mass of exploding fuel (kg)

M = molecular weight of the fuel

The damage assessment due to explosion is calculated from the scaling laws which are stated as follows:

$$d_s = \frac{d_a (P/P_0)^{1/3}}{(W'/W_0)^{1/3} (T/T_0)^{1/3}} \quad (3-20a)$$

$$t_a = \frac{t_s (W'/W_0)^{1/3}}{(P/P_0)^{1/3} (T/T_0)^{1/6}} \quad (3-20b)$$

$$I_a = \frac{I_s (W'/W_0)^{1/3} (P/P_0)^{2/3}}{(T/T_0)^{1/6}} \quad (3-20c)$$

where:

d_s = scaled distance from explosion center (m)

d_a = actual distance from explosion center (m)

P, T = pressure and temperature of the atmosphere in the actual case (bar, °K)

*Only overpressure effects are currently being depicted in the graphical displays for explosion damage.

P_0, T_0 = pressure and temperature of the atmosphere in the case of the reference explosion ($P_0 = 1$ bar, $T_0 = 288.15^\circ\text{K}$)

W' = effective energy yield of the actual explosion

W_0 = energy yield of the reference explosion (1 kg of TNT yields 1.12×10^6 calories; thus, $W_0 = 1.12 \times 10^6$ calories)

t_a = actual time (s)

t_s = scaled time (s)

I_a = actual impulse (N-s/m²)

I_s = scaled impulse (N-s/m²)

These laws are simplified considerably if the actual explosion is assumed to occur in the same atmosphere as the reference explosion. Since ratios of absolute values for atmospheric pressure and temperature are raised to fractional powers, these factors are close to unity even when the reference and actual atmospheres are not identical. By assuming essentially identical atmospheres, one obtains:

$$d_s = \frac{d_a}{(W'/W_0)^{1/3}} \quad (3-21a)$$

$$t_a = t_s (W'/W_0)^{1/3} \quad (3-21b)$$

$$I_a = I_s (W'/W_0)^{1/3} \quad (3-21c)$$

For an explosion with a center on a rigid surface, the surface reflects completely all explosive energy impinging upon it. If the ground can be considered as a rigid surface, then the effective energy yield will be twice the explosive energy yield, or:

$$W' = 2W \quad (3-22)$$

The data for a reference spherically symmetrical explosion are stored in the computer. If the critical impulse for body injury is determined, the critical distance for a certain explosive mass can be obtained from equations (3-20a) or (3-21a) and the reference data. The procedure is as follows:

1. Compute W and W' from equations (3-19) and (3-22).
2. Compute dose v for a given probit from equation (3-8) for impulse.
3. Let $I_a = v$ and compute I_s from equations (3-20c) or (3-21c).

4. From the reference data, find the scaled distance d_g corresponding to the I_g .
5. Compute actual distance d_a which is the radius of the constant casualty curve.

C. MODIFICATION OF VM AND ADDITION OF NEW SUBROUTINES

The VM has been modified and several new subroutines have been added. A control variable has been installed by which the user can direct the program to generate the plotting data. The new subroutines are:

- PLOTIN:** Based on the physical properties of the vapor, this subroutine calls various subroutines to generate the plotting data.
- PUFFLO:** This subroutine generates the coordinates for the lower threshold value curve or the lower flammability curve for the puff model.
- PLMPLO:** This subroutine generates the coordinates for the lower threshold value curve or the lower flammability curve for the plume model.
- FLASPL:** This subroutine calculates the coordinates for the constant lethality curve and nonlethal curve from a flash fire burn. Five curves for each case are generated, corresponding to 1, 25, 50, 75 and 99 percent casualties.
- TOXPLO:** This subroutine calculates the coordinates of constant casualty curves from toxic gas for both puff and plume models. Five curves for each case are generated, i.e., 1, 25, 50, 75 and 99 percent casualties.
- EXPLO:** This subroutine generates the coordinates of constant casualty curves from explosion including peak overpressure, impulse, and flying fragments. It also generates the constant damage curves for structures.

Each of the subroutines which produce the damage extent data bases for eventual conversion to visual displays is keyed on a three- or five-tiered probit analysis scheme, in which three (1%, 50% and 99%) or five (1%, 25%, 50%, 75% and 99%) curves corresponding to distance at which each percent of damage is likely to occur are computed to form the curve family.

The data bases per curve family are coded using a general format which enables subsequent reading of the data in a simple manner. The "write" format is in the following order:

NPLOT,I,J,X(J),Y1(J),Z

where:

NPLOT is an integer value (I3) corresponding to a plot file code for subsequent sorting and identification by the display programs.

I is the number of the current set of data corresponding to either a certain elapsed time or distance, incremented by a constant amount

J is the number of the current set of data corresponding to I and to a particular probit level

X(J),Y1(J) is the ordered set of coordinates computed to correspond to I and J, converted to units of meters

Z is the alphanumeric name of the cell corresponding to I.

There are certain exceptions to the variable types written in this format. The entire set of cells from the coordinate-transformed Geographical file is written onto the Output file (TAPE36) as X(J) and Y1(J), with NPLOT=1, and J not used--instead, I is used as the increment index. In PLOTIN, NPLOT=199 and the values of the flammability and toxicity flags are stored in I and J, respectively, with the values of the total mass of gas (sum of data in field numbers 4001 and 4023) and exploded mass, if any, stored in X and Y1. In VMEEXEC, NPLOT=200 and the values of the wind speed and either lower flammability limit (g/cm³) or irritation threshold (g/cm³) are stored in X and Y1, respectively.

In subroutines FLASPL and EXPFLO, the number of the probit curve is stored in I, the number of the cell in which ignition occurs goes in J, and the radius corresponding to I is placed in X, with Y1 getting the value of the percentage corresponding to I and Z left unwritten (as also is the case in all other TAPE36 writing sections, except for the one transferring the values of the transformed cell coordinates).

PUFFLO sets NPLOT=2 for the puff irritation (toxic submodel) curve family and NPLOT=3 for the puff lower flammability limit family.

PLMPLO sets NPLOT=4 for the plume irritation curve family and NPLOT=5 for the plume lower flammability limit family.

FLASPL sets NPLOT=6 for the curve family corresponding to flash fire death (lethality) and NPLOT=7 for the family corresponding to flash fire first-degree burn (injury), regardless of whether the plume or puff model is used.

TOXPLO sets NPLOT=10 for the toxic death curve family and NPLOT=11 for the toxic injury family if the plume model is used, or NPLOT=12 for toxic death curves and NPLOT=13 for toxic injury curves if the puff model is used.

EXPFLO sets NPLOT=17 for the death from overpressure curve family, NPLOT=18 for the injury from overpressure family, and NPLOT=19 for the structural damage family, again regardless of dispersion model type.

All of the subroutines which perform calculations for the plot file data base contain zero-divide safeguard coding. The user is cautioned that if errors occur in the execution of earlier subroutines they will be passed into the display subroutine sections (if a "fatal" error does not prevent this) since no range checks on the incoming data are performed.

Besides the additional subroutines for the VM, four independent programs have been created for plotting.

DISFTN: This is a procedure file which controls the use of DISSPLA, a plotting software package, under NOS. The procedure file takes a source file, compiles it, links with the DISSPLA library, and executes it. DISFTN also retrieves a Tektronix terminal status definition file, TEKANS (for Model 4010-4012 configurations only).

The following are the three source files:

TOXDISP: This program requests and reads the plotting data file name and attaches the file to the user's workspace as a secondary file. It next requests and reads a user-supplied 20-character or less plot title, for identification purposes, to which it adds its own title. It also reads the cell number of new spill location (if any) and the new wind direction with the x-axis (if any). Then the program reads the toxic data from the attached file, rearranges the data if necessary, and determines the scale of the graphs. It plots the lower threshold value curves, constant lethality curves and constant nonlethality curves (if any) for the puff or plume model.

FIRDISP: This program is similar to TOXDISP except that it plots the lower flammability limit curves, constant lethality curves and nonlethality curves from the flash fire or fireball model.

EXPDISP: This program is also similar to TOXDISP, but it will not read the new wind direction because the explosion effect is one of spherical symmetry. It plots the constant lethality and nonlethality casualty curves from explosion and the constant structural damage curves due to overpressure.

Appendix D contains a listing of the above programs and DISFTN.

Only one additional user input variable for the VM is needed and that is the plotting control variable, KPLOT:

Field Number	Default Value	Unit	Variable Name	Comment
4014	0	none	KPLOT.	=0, no plotting data generated; =1.0, generates plotting data

Execution of the VM with a request for plot file generation normally results in an increase in system resources demand of approximately 75% to 100% beyond a non-plot file generation run using otherwise identical input files. A successful execution of the former type results in TAPE36, the plot data base file, routed to the NOS disk file via station KEB immediately after PHASE1 is executed, just prior to the loading of PHASE2. TAPE36 is transmitted as a direct-access (ATTACH-type) file, since it will normally be quite lengthy, and is renamed using the system-declared name for the particular job (e.g., AVAKCSP), and must be called for under this name, not as TAPE36. A scan of the dayfile attached to the run or of the current NOS disk catalog will produce the name of the routed file.

A special Cycle-15 VM jobstream named DISPVM has been written and stored in the S7205 disk catalog for easy usage of the KEB routing facility. The jobstream is presented in Figure 3-1 and is submitted after calling in the appropriate Geographical file to the workspace and renaming it GEOG, as well as naming the Input file VMINPUT, using this command:

```
SUBMIT,DISPVM,ST=stationid,T.
```

D. USAGE OF THE DISPLAYS

The user can run the VM by remote job entry from NOS by using either UIM version alone (not file -RUIM) or by creating the input file manually. The time-sharing user can submit the job by entering the SUBMIT command. The format is:

```
SUBMIT,job file name,ST=id,T.
```

where id is a three-character site identifier that specifies what SCOPE 3.4 site should receive the transmitted file (for the Eastern CYBERNET Center at Rockville, Maryland, the id is ECZ). After the job has entered into the local batch queue, the system responds:

```
hh,mm,ss,jobname
```

where hh,mm,ss, is the time that the job entered the batch queue (hours, minutes, seconds). The jobname will also be the name of the generated plotting data file which is routed back to NOS. The user is advised to write this name down for reference. The following is an example:

```
/SUBMIT,DISPVM,ST=ECZ,T.  
10.08.12.AVDOAYO  
/
```

The first line is typed by the user and the second line is printed by the terminal. DISPVM is the job file and AVDOAYO is the system-declared jobname and also will be the name of the generated plotting data file, which will appear in the NOS disk catalog as a direct access file.

In the Geographical file, the cells are identified by the ID numbers which are usually the same as the census tract codes. When the VM reads the file, it rearranges the cells into sequential numbers (1,2,3...) and calculates the transformed coordinates (x and y) for each cell using the spill location as origin. In the printout of the VM job, the user finds

FIGURE 3-1

VM Display Plot File Routing Jobstream: DISPVM

a table called Geographical Data which lists the sequential number, cell ID, latitude, longitude, x-coordinate, and y-coordinate of each cell. The reason we describe this process in detail is that in the display, the cells' locations are represented by the centers and marked with the sequential number. With the Geographical Data table and the census map, the user can then find the area covered by the vapor clouds.

The following example illustrates the steps for producing display output. In the example, it is assumed that: (1) the user wants to display toxic casualties, so the program TOXDISP is used; (2) the plotting data file is AVDOAYO; (3) the user wants to change the spill location to cell 35; and (4) the user wants to change the wind direction to -15 degrees from the old wind direction. In the example, the letter "U" (USER) means that the user types in the data or answer, the letter "T" (TERMINAL) means that the terminal prints the message, and (cr) means to depress the return key.

1. Sign on the system
2. U: OLD,TOXDISP (cr)
T: READY.
3. U: -DISFTN(F=TOXDISP) (cr)
4. T: WHAT IS THE PLOTTING FILE NAME:
U: AVDOAYO (cr)
5. T: ENTER THE PLOT TITLE (<21 CHARS.)--
U: CLX SPILL /RUN 25 (cr)
6. T: DO YOU WANT TO CHANGE THE SPILL LOCATION?
ANSWER 1 FOR YES, 0 FOR NO
U: 1 (cr)
7. T: WRITE THE CELL NUMBER WHERE THE SPILL WILL OCCUR
U: 35 (cr)
8. T: DO YOU WANT TO CHANGE THE WIND DIRECTION FROM THE ONE
WHICH YOU USED TO CALCULATE THE PLOTTING DATA?
ANSWER 1 FOR YES, 0 FOR NO
U: 1 (cr)
9. T: WRITE THE WIND DIRECTION IN DEGREES: COUNTERCLOCKWISE
IS POSITIVE; CLOCKWISE IS NEGATIVE
U: -15.0 (cr)

With these data entries, the computer starts to execute and display automatically. A typical 3-frame run requires about 10-20 minutes of time at 300 BAUD (about 4-10 minutes at 1200 BAUD) and generally "costs" about 80 SBU's.

The user may obtain hard copies of the displays by (1) Polaroid photography of the finished frame on the CRT terminal (each frame generally is held for about 20 seconds by the computer before erasure) or by (2) saving the display program-created intermediate plotting data file, named NPFIL, and processing it for a CALCOMP batch job to produce India-ink-on-paper reproductions of the image frames. For purpose (2), a special submission jobstream, CALPLOT, has been created and is described next.

If the user is satisfied with the plot frames, immediately after the system returns control of the CRT terminal to him, he should proceed to reprocess the intermediate, temporary plotting file named NPFILE (for "Neutral-Picture FILE") into a CALCOMP-compatible data file named PLOTf. This is done using the following commands:

```
U: NULL      (cr)
T: READY.

U: REWIND,NPFILE      (cr)
T: READY.

U: CALL(UNIPROC,S=2POST(DEVI=ROCKVIL)      (cr)
T: (after a short delay)
  1 UNIPOST V2.1 INPUT DIRECTIVES
  ?
U: $      (cr)
```

The computer will then take a few seconds to process the NPFILE and will return with:

```
T: READY.

U: GET,CALPLOT      (cr)
T: READY.

U: SUBMIT,CALPLOT,ST=stationid,T      (cr)
T: hh,mm,ss,jobname
```

The listing of CALPLOT and its associated information file, PLTINFO, is presented in Appendix B.

To pick up the CALCOMP plots, the user needs to have placed his phone number and name in PLTINFO so that the local CDC cluster center can notify him when they are ready for pickup (generally, allow one full day).

Example CALCOMP plots are presented as Figures 3-2 through 3-21 on the following pages and illustrate the outputs from the various display programs.

E. FLOW DIAGRAMS

Figures 3-22 through 3-30 (pp. 3-36 through 3-48) depict the revised and appended flowcharts illustrating the changes made in incorporating the display plot file producing code. Figure 3-30 shows the flowchart for program TOXDISP; since FIRDISP and EXPDISP are similarly configured, they are not shown.

Chapter 4

GEOGRAPHICAL/DEMOGRAPHIC FILE GENERATION FOR NEW YORK AND LOS ANGELES HARBORS

A. INTRODUCTION

Under Task 3 of this study to prepare the Vulnerability Model (VM) for operational use, two Geographical/Demographic files were generated for the New York Harbor and one file was generated for the Los Angeles Harbor area. Together with the previously created New Orleans file (GEONOL), there are now four files of several hundred cells each which can be accessed through the User Interface Module (UIM) or directly read into the VM.

The remainder of this chapter is devoted to descriptions of these files and discussion of how they were created.

B. APPROACH

The Geographical/Demographic files were generated by selective searches of census data contained within the U.S. Department of Commerce's Master Enumeration District List (MEDList). The data were provided on magnetic tapes arranged by census region, generally with two regions' data files per reel of tape.

The MEDList tapes contain census data arranged by state, then by county, then by census tract, and finally by enumeration district plus block group (if any). Our searches concentrated on extracting appropriate census tracts plus enumeration districts for targeting as cells in the Geographical/Demographic files. There is a great deal of other data available on these tapes concerning alternative code identifications for each tract. We selected the housing counts and population counts, and the latitude and longitude as well as the tract identification (tract number plus enumeration district number) for the Geographical files; and added to each line of extracted data an assumed ignition code of +3* (capable of igniting any material with flashpoint less than 200°F) and an assumed dollar value of \$60,000 per structure per tract.

The latitudinal/longitudinal positions of each tract were used as keys for selection or rejection in making the searches. The objective of each search was to produce a file of 350 to 390 land area cells based on a presumed likely spill location, and then water area cells were added nearby the putative spill location to complete the file. Since the water cells are critical in establishing whether or not the program will even compute the cause of a spill, a fairly wide expanse of water was used to locate these cells so as to provide the VM user with flexibility in selecting

*Except for the water cells of the Los Angeles and two New York area files, to which were assigned ignition codes of zero (no potential to ignite).

spill locations. (The criterion used in the VM for going ahead with computations is that the selected spill location must be within 20 seconds of latitude or longitude of a cell—20 seconds is about one-third of a mile or about 0.53 kilometers.)

Each generated Geographical file was then given a systematically determined name and UIM code. The names are based on the abbreviation of the port city that was the basis for selecting the tract cells, prefixed by the syllable GEO and suffixed by an identifying digit which corresponded to the sequential order in which the file was made. The files generated were:

- GEOLAL
- GEONY4
- GEONY6

C. DESCRIPTIONS OF FILES

The GEOLAL file was produced for the Long Beach area of Los Angeles, California. There are 361 land area cells and 6 water area cells, for a total of 367 cells. The file covers an area 9 miles north, 2 miles west, and 8 miles east of a putative spill site in the San Pedro Harbor, with coordinates of 33°42'34" N. and 118°16'19" W. On land, it extends northward to Lakewood, eastward to the Long Beach Airport, and westward to the Torrance Municipal Airport. The resulting area of coverage resembles a square. Figure 4-1 is a map of the Los Angeles area showing the boundaries of this file. Figure 4-2 is a map of the harbor area showing the location of the census tracts contained in the file. In general, each tract contains several block groups which constitute the individual cells in the file.

Figure 4-3 is a map of the New York Harbor area showing the location of the two Geographical files created for that area. Figures 4-4 and 4-5 are large-scale maps showing the location of the census tracts that make up the GEONY4 and GEONY6 files, respectively. Again, each census tract is composed of several cells (block groups).

The GEONY4 file was produced for the Perth Amboy, New Jersey/New York area. There are 358 land area cells and 6 water area cells, for a total of 364 cells, in this file. The area of coverage is a cut square, of side and length equal to 16 miles, centered about a hypothetical spill site located at 40°30'40" N. and 74°15'35" W. On land, it extends northward to an imaginary line connecting Plainfield and Linden, N.J., westward to Edison, N.J., and southward to Browntown, N.J.; the eastern boundary varies—it is approximately at Grasmere in New York and at the Middlesex-Monmouth County lines in New Jersey.

The GEONY6 file was produced for the South Brooklyn-Coney Island/New York area. There are 380 land area cells and 6 water area cells, for a total of 386 cells, in this file. The area of coverage is a rectangle

FIGURE 4-4. GEONY4

FIGURE 4-5. GEONY6

with long sides equal to 7 miles and short sides equal to 4 miles. The southern base of the square has a midpoint at 40°31'24" N. and 74°00'00" W. It extends northward to the center of Prospect Park, eastward to Brooklyn College (CUNY), and westward to Owl's Head Park. The southern terminus is at an imaginary line approximately 3 miles south of the Coney Island shoreline.

A previously created file, GEON01, exists for New Orleans, Louisiana. There are 252 land area cells and 84 water area* cells, for a total of 336 cells, in this file. The reason for the great number of water area cells is the fact that the water body of interest, the Mississippi River, cross-cuts the city; thus, this is a case where numerous water cells are needed to provide the user with flexibility in selecting potential spill sites for modeling (whereas in New York and Los Angeles, the geographical areas primarily cover short strips of shoreline, for which only a few possible spill sites exist). The area of coverage is approximately 9 miles square and is bounded to the north by Lake Pontchartrain's southern shoreline, to the east by Arabi, to the west by Metairie, and to the south by a line extending approximately parallel with the Mayonne Canal. A map of GEON01 is presented as Figure 4-6.

Since the user of any of these files is bound to the criterion that the selected spill site must be within 20 seconds of latitude or longitude of any (water) cell, Table 4-1 presents the coordinates of the water cells developed for these files.

For linkage to the UIM, four-digit codes have been assigned to each file. The codes were assigned on the basis of state numbers as they occur in the MEDList tapes, the port city number associated with each state, and the sequential number of the file belonging to each port city. The table of codes is displayed below:

TABLE OF UIM CODES

Port City	File Name	UIM Code
New York	GEONY4	3611
New York	GEONY6	3612
New Orleans	GEON01	2211
Los Angeles	GEOLA1	1611

*All of which have ignition codes of +3.

D. PROBLEMS ENCOUNTERED

The tapes were searched on the basis of state and county codes as well as latitude/longitude boundaries to produce the Geographical/Demographic files. Although no major computer-related problems were encountered, there were some intersystem incompatibilities that had to be dealt with.

In particular, the tapes were originally made on IBM equipment. Since four of the five tapes contained two-region files, it was necessary to "read" past tape-file markers placed on these tapes to serve as separators. On IBM systems, a double tape mark is placed between files to act as the separator; on CDC systems, only single marks are used in this case, and a double mark signals "end of information" on a tape and cannot be read past by the software. Thus, in order to read the second file on each of the IBM MEDList tapes, they had to be physically recopied as the first (and only) file on separate blank tapes and then read into the CDC system. Also, they had to be converted into CDC-readable record format using the RCOPY utility.

The computer programs that extracted the sets of census tracts for the Geographical/Demographic files were designed to sort through the master tapes and then to reformat the data into VM-acceptable arrangements. In particular, this involved picking out the relevant data from a format in which they were represented as degrees and fractions of a degree into integer degrees, minutes, seconds (DDMMSS) format. The conversion program, ICON, and a sample sort program for the New York area, CENSRCN, are presented as Figures 4-7 and 4-8.

E. USAGE OF THE FILES

These files are accessible either by referencing their names in a VM submission jobstream or by referencing their four-digit codes in a UIN-assisted VM run.

The VM will read in a selected file as it stands, sequentially assign cell numbers to each cell-tract ID, and then compute the relative distance in an x-y Cartesian plane from the selected spill site. These data that are printed are in the Geographical Data section of the VM results print-out. It is important for the user to keep in mind that all subsequent cell number references are to the VM-assigned sequential cell numbers and not to the cell ID's that appear on the Geographical file maps. To track back a cell, the user must refer back to the aforementioned Geographical Data Table to get the correspondences.

Briefly, to use these files in a VM simulation through execution of the UIN, the user prepares a data file as he/she normally would through the UIN, using the Geographical file maps to produce the appropriate code and to aid in selection of a reasonable spill site. The latitude and longitude "20-second" criterion must be kept in mind in choosing a spill site. After a successful VM run, the user then refers to the Geographical

CENSrch, Program To Sort Through
the New York/New Jersey Census File

Data Table in the printout to make the conversion between the cell numbers identified in the simulation to be affected (or not affected) by the spill of hazardous cargo and the cell ID's (tract codes) listed on the appropriate map. Not all of the cells listed in the Geographical files will be found on any one map, because some are resolved down to enumeration districts and block groups that are too small in one area to be noted on the maps; in this case, the user must refer to the integer part of the ID to locate the area of concern.

Chapter 5

SPILL SIMULATIONS

A. OBJECTIVES

Using the UIM/VM system, spill simulations were performed for a number of chemical cargoes selected by the USCG. The objectives of the simulations were threefold:

- To test and check out the utility and effectiveness of the UIM using untrained operating personnel.
- To validate the UIM/VM system for specific chemicals of interest to the USCG.
- To determine the relative hazard ranking of the chemicals selected for simulation.

B. APPROACH

Initially, 27 chemicals were selected as candidates for simulation. The selection was based on their hazard potential as estimated by their chemical properties (chiefly toxicity or flammability) and their shipment characteristics. The various properties of these chemicals needed for the UIM, including the probit coefficients for the toxic chemicals, were developed and inserted in the UIM as discussed in Chapter 2. Then from this list of 27 candidate chemicals, USCG personnel selected 15 chemicals for spill simulation.

Since one of the objectives of the spill simulations was to perform a hazard ranking of the chemicals based on the VM results, canonical spill scenarios were devised which all 15 chemicals could be subjected to. Three standard scenarios were developed, and simulations were run for all 15 chemicals for each of the scenarios.

The simulations were run using the UIM and, for two of the three scenarios, the simulations were performed by personnel with no prior computer experience. These simulations provided proof testing of the utility of the UIM operational manual as well as that of the UIM itself.

The results of the simulations were analyzed in three ways. First, they were examined from the standpoint of UIM effectiveness and utility, with particular attention given to the comments and recommendations of the novice users. Based on recommendations produced by this analysis, appropriate modifications were made to the UIM to improve its ease of use and value. Secondly, the simulation results were examined from the standpoint of compatibility of the UIM with the VM and validity of the VM results. Any inconsistencies or errors found in the VM program as a result of this analysis were corrected and the affected simulations were rerun. Lastly,

the simulation results were analyzed for the purpose of ranking the 15 chemicals according to their casualty-producing potential. Based on a careful scrutiny of the results for all three scenarios, a hazard ranking of the chemicals was produced.

C. CHEMICALS SELECTED FOR SIMULATION

Table 5-1 presents the hazard properties of the chemicals selected as candidates for spill simulation. The table gives the type of hazard (flammable or toxic), the lower flammable limit or threshold limit value,* the fire hazard rating given by Sax,** and the toxic hazard rating given by USCG-388.***

Fifteen chemicals were selected for spill simulation from the list of candidate chemicals. The selection was made by USCG personnel based on their interest in particular chemical cargoes. Table 5-2 lists the 15 chemicals and enumerates for each the type of hazard to be simulated and the cargo characteristics, including tank capacity, cargo temperature, and cargo pressure. The tank capacity represents the maximum size of a single tank that is customarily used for that chemical in U.S. marine transportation.

D. SCENARIO CHARACTERISTICS

The spill locations and the wind directions specified for the three canonical spill scenarios at Perth Amboy, Coney Island, and Los Angeles are depicted in Figures 5-1, 5-2, and 5-3, respectively. Also noted are the assumed water and air temperatures.

The spill for each scenario was assumed to be caused by a 2-meter-diameter rupture in the cargo tank just above the waterline. The rupture characteristics and tank position with respect to the waterline are depicted in Figure 5-4. The actual amount spilled was computed by the VM (Model A) and was dependent on the size of the tank which was, in general, different for each chemical. Since tanks were assumed to be situated for the most part above the waterline, almost the entire content of each tank was spilled and the computed amount turned out to be roughly 98% of the tank capacity.

 $c = 1$ meter

FIGURE 5-4. Rupture Characteristics

From the standpoint of hazard ranking, the use of spill sizes which are dependent on the maximum tank capacities for the chemicals is considered to be a valid analytical technique even though it results in different spill sizes for the different chemicals. The magnitude of the hazard is to a large extent dependent upon the amount spilled, which in turn is dependent on the size of the tank. Thus, the size of the tank should play a part in the ranking of the hazards, which it does in the method of analysis used here.

E. CHECKOUT OF UIM/VM SYSTEM AND SPILL SIMULATION PRODUCTION

1. Initial System Test

To check out the UIM/VM system, spill simulations were run first for the Perth Amboy scenario for all 15 chemicals. VM results were carefully examined for errors and inconsistencies. This exercise yielded several logic errors that needed to be corrected. Also, several cosmetic improvements were made to the VM output tables to enhance their ease of use. Once these modifications were made, the spill simulations were run for all three scenarios (including a rerun of the simulations for Perth Amboy).

2. Production Runs

The production runs of the spill simulations were performed for the most part by non-computer-oriented personnel. Two methods were used to train the operators. For the operators who had some prior knowledge of the VM (but no computer experience), training was provided in a short orientation session of about one-half hour in duration. Then, during their first UIM session an experienced operator stood by to assist the novice operators when necessary. After the UIM initial session, the novice was generally on his own.

The second type of training was attempted for those personnel who were totally unfamiliar with the VM. These persons were asked to study the UIM manual for several hours. Then the trainee was given a spill scenario to run and, as before, the experienced operator was available to assist the novice during his first UIM session.

Both methods of training the novice operators were found to be effective. After the first session, the first-time users could set up and run VM simulations completely on their own. The only assistance needed was for unusual computer system problems or for interpreting the VM output.

3. VM Modifications

As previously discussed, the initial checkout simulations at Perth Amboy identified several VM program errors and inefficiencies. Likewise, the production runs resulted in several recommendations for simplifying and clarifying the VM output tables. The modifications made to the VM program as a result of these findings are described below.

The time-incremented radiation flux tables, which have no utility since the revision of the flash fire model, were removed from the VM output.

An unused variable, field ID 4012, was reactivated as a flag to suppress printout of the ppm concentrations table, since this could be redundant in light of the fact that a concentrations table in units of kg/m^3 is also printed. If the new variable PPMSUP is set to 1, the table is not printed; if set to any other value or not set at all, the table is printed. The kg/m^3 concentrations table is printed regardless of the value of PPMSUP.

In subroutine DOSAGE, the time-concentration product computation routine for toxic chemicals, it was discovered that the interior dosage was being incorrectly computed due to a units error; this has been rectified. Also, a mistyping of the air temperature variable, AIRTEM, leading to a misassignment of zero for this variable in this subroutine has been corrected. Further, if a toxic spill run is requested, the Ignition Output Table will no longer be printed. This has been implemented since in the case of a toxic spill, very few of the entries in this table are applicable, and those that are applicable are of minor importance to the analyst.

In the flash fire subroutine, FLFIRE, it was discovered that the formula used for computing fireball size was incorrect, and has been amended to reflect the change. In particular, the density of the fuel vapor is now being used rather than that of the combustion products. Also in this subroutine, due to an earlier VM change, the value of the secondary fires flag, NSF, was being incorrectly assigned and was causing a fatal FORTRAN error to occur in VMEKEC when no request for secondary fires analysis (3004=0) and ignition occurred. This has been corrected both here and in main routine VMEKEC.

In MODZ, the values for sigma-y and sigma-z at time of ignition were not being printed when the plume submodel was in effect. This led to misleading default values of zero being printed in the Ignition Output Table for these variables. This has been reprogrammed to be consistent with the puff submodel printout format.

In subroutine PATH, a logic error was causing execution of Model F, which determines the amount of time needed to dissolve a water-soluble chemical, to be executed for certain immiscible liquids. This was corrected by deleting the setting of the model number corresponding to F to a non-zero number (5) if such chemicals were being considered.

In the spillage rate determination section of the VM, certain combinations of tank geometry and insulative type were causing floating point overflows in subroutine RLJTC. This only occurred if adiabatic tank conditions (2006=1) were specified, and has been corrected by including impending overflow-sensing lines of code to protect against this condition by flagging for termination of the particular loop sequence where this may occur, and continuance of normal flow.

In Phase II, the blast damage tables were often printed out with many subtables showing no apparent damage for some cells. The threshold level for the selection of blast damage printout or nonprintout has been reset, and very few "zero subtables" are now being observed, thus reducing a potential source of confusion.

Finally, for test purposes, it is now possible to bypass the PATH subroutine and the escape-, spreading-, and evaporation-rate determining subroutines entirely, and to go directly to MODC by setting reactivated field ID 4013, BYP, to 1 in the input file (default is zero). This forces the VM to use the user's input file values for total mass liberated (TMV, 4023) in lieu of the calculated values; and in the case of the plume (continuous spill) submodel, the minimum of either time to effect complete evaporation (TEVAP, 4016) or the value of the first time in the first-specified time sequence* (TLAST, 5050, which is derived from field ID's 6001, 6004 or 6007) for determining the value of Q_B , the source strength item. Therefore, when using this option for a plume simulation (5010=1), the user must specify a value for field ID's 4023, 4016 and either 6001, 6004 or 6007, or else execution-time errors will occur.

*When specifying the time sequence for a toxic chemical, a time progression should not be used since the VM will select the first time specified in the progression, perform a computation set based on it, and then will directly proceed to Phase II, ignoring any remaining time increments.

F. SIMULATION RESULTS

The principal results of the spill simulations for the 15 chemicals at Perth Amboy, Coney Island, and Los Angeles are presented in Table 5-3. Given are the number of deaths, injuries and, in the case of flammable chemical spills, the number of buildings destroyed. The figures for deaths and injuries are the total casualties for both outdoors and indoors personnel. The parenthetical values show the portion of the total occurring indoors. For some of the toxic chemicals, injury probits have not been developed (for lack of data) and, thus, injuries were not computed. Comments are given in the last column of Table 5-3 regarding the nature of the cloud simulated (puff or plume) and the solubility and volatility of the chemical. These comments are useful in explaining and interpreting the results.

For ethyl ether a spill from two tanks was simulated (i.e., 6,000 m³ rather than 3,000 m³). A spill from a single tank resulted in zero casualties for ether, but an examination of the results disclosed that the vapor concentrations at the closest cells were very close to the lower flammable limits. Consequently, a double size spill was simulated to provide a means of differentiating between this marginally hazardous chemical and the other zero casualty chemicals which produced downwind concentrations far below hazardous levels.

Acetaldehyde, acrylonitrile, dimethylamine, and propylene oxide produced no damage due to their high solubility. As evident from the following table, only a very small percentage of the spilled material vaporized and the rest went into solution. Due to the small amount of vapor, the highest concentration at the nearest cell was orders of magnitude below the lower flammable limit, as noted for acetaldehyde and propylene oxide.

Chemical	Mass Vaporized (kg)	Mass Vaporized Mass Spilled (%)	Concentration at Nearest Cell (kg/m ³)	Lower Flammable Limit (kg/m ³)
Acetaldehyde	1,890	0.008	8.2×10^{-6}	7.6×10^{-2}
Acrylonitrile	240	0.010	Not recorded in VM output	Non-flammable
Dimethylamine	401	0.002	-	-
Propylene Oxide	1,300	0.005	5.0×10^{-6}	5.0×10^{-2}

TABLE 5-3. Results of Spill Simulations

CHEMICAL NAME (CODE)	PRINCIPAL HAZARD	TANK SIZE (m ³)	DEATHS			INJURIES			BUILDINGS DESTROYED			REMARKS

Notes: Perth Amboy: stability class F, closest downwind cell at 0.4 km.
 Coney Island: stability class D, closest downwind cell at 5.4 km.
 Los Angeles: stability class D, closest downwind cell at 1 km.
 Highly volatile: boiling point less than sea temperature (68°F).
 Moderately volatile: boiling point between sea temperature
 and 190°F.
 Low volatility: boiling point greater than 190°F.

-- = no injury computations made due to lack of
 injury prohibits in VM.
 NA = not applicable.
 () = casualties to personnel indoors.
 *Two tanks assumed spilled; simulation for a
 single tank resulted in no casualties.

The only other chemical that resulted in no damage for all three scenarios was octane. This was due to its relatively low volatility. The data below compares the source strength of octane to the other flammable chemicals which formed a plume of sufficient concentration to ignite at Perth Amboy. The source strength of octane is much less than that of the four chemicals which ignited. Note that the time of evaporation for octane is roughly an order of magnitude greater than the others.

Chemical	Time of Evaporation (min)	Plume Source Strength (kg/sec)	Result at Perth Amboy
Ethyl Ether	33	485	Ignition
Methyl Chloride	.27	215	Ignition
Octane	200	52	No ignition
Pentane	25	426	Ignition
Vinyl Chloride	18	342	Ignition

The maximum vapor concentration of octane at the closest cell at Perth Amboy was 3.5×10^{-3} kg/m³ and the lower flammable limit is 4.9×10^{-2} , thus no ignition occurred.

Six chemicals produced casualties at Perth Amboy, but not at the other two spill sites. These were the four flammable chemicals that ignited in the above table plus the two toxic chemicals, toluene and ammonia. All six of these chemicals exhibited evaporation times more appropriate to plume formation than puff. Absence of casualties at Coney Island and Los Angeles was due to the greater distances between spill site and nearest downwind cell and to the less stable atmospheric conditions that existed at these sites compared to Perth Amboy. The nearest cell distances at Coney Island and Los Angeles were 5.4 km and 1 km, respectively, compared to 0.4 km at Perth Amboy. Thus, because of the near-in spill site and the very stable air assumed at Perth Amboy, the concentrations in the plumes were sufficiently high to cause damage at the near-in cells. But at Coney Island and Los Angeles, the lowering of the stability and the increase in distance were sufficient to reduce the plume concentrations to below hazardous levels. Thus, the six chemicals can be considered to be marginally hazardous; that is, hazardous only under a fairly narrow set of conditions.

Four chemicals resulted in casualties at all three spill sites. These were chlorine, LNG, LPG, and methyl bromide. All four of these chemicals were both highly volatile and immiscible, and the evaporation times were sufficiently low to cause the vapor cloud to exhibit puff-like behavior with concomitant high concentrations. The table below shows the evaporation times computed by the VM for each of the four chemicals.

Chemical	Evaporation Time (min)	Boiling Point (°F)
Chlorine	0.3	-29
LNG	4.1	-258
LPG	6.5	-40
Methyl Bromide	0.6	+40

Chlorine's evaporation time was shorter than the others, due principally to the relatively small size of spill. Because liquid methyl bromide is heavier than seawater, the VM selected a different vapor formation model for methyl bromide than for the others: the sinking and boiling model rather than the floating cryogen model. The sinking and boiling model simulated very rapid evaporation, presumably enhanced by boiling turbulence and the concomitant rapid heat transfer.

Because of the rapid cloud formation, the vapor concentrations of chlorine, LNG, LPG, and methyl bromide were sufficiently high to remain hazardous for long distances under class D stabilities. For chlorine, LNG and LPG, the casualties were greater at Coney Island than at Perth Amboy or Los Angeles because of two effects:

- higher population density
- larger vapor cloud area due to lower stability and greater distance to vulnerable resources.

The amounts spilled and the hazard properties of these three chemicals were sufficient to cause the chemicals to remain extremely hazardous even with the dilution resulting from larger distances and lowering stabilities.

In the case of methyl bromide, the dilution due to greater distance and less stability was sufficient to greatly reduce the casualties at Coney Island and Los Angeles, relative to the casualties at Perth Amboy.

For LNG and LPG spills, the vapor clouds were ignited by the geographic cells first encountered, when most of the cloud was over the water and only a small portion intersected the land. This had the effect

of minimizing the casualties, especially at Los Angeles where the geographical cells that bordered the harbor were not heavily populated. The reason the LNG spill resulted in less fatalities than the LPG spill at Los Angeles was due to the greater penetration of the smaller LPG vapor cloud before ignition. This is purely a chance result having little bearing on relative hazard potential of the two chemicals.

G. HAZARD RANKING

The results of the simulations have been analyzed for the purpose of ranking the chemicals according to their relative hazard potential. The principal measure of hazard potential used in the analysis is the number of fatalities, since it is the most consistent and accurate measure produced by the VM. Some consideration is given to number of injuries and buildings destroyed; however, injuries are not computed for some toxic chemicals (insufficient medical data for estimating injuries) and structural damage of course is not computed for toxic chemicals. Thus, injuries and structural damage are useful only for ranking between chemicals for which the calculations were made.

A second hazard factor used in the hazard ranking is specific lethality. Specific lethality is defined as the deaths per cubic meter of material spilled. This hazard measure normalizes the effects of all chemicals for a given quantity of chemical spilled and provides a measure of the relative hazards of the chemicals for the same size of spill.

Table 5-4 is a tabulation of the hazard factors (total deaths and specific lethality) derived from the VM simulations for the 15 chemicals and the three scenarios. The chemicals are grouped according to solubility and volatility. The most hazardous category is presented at the top of the list (insoluble and highly volatile) and the least hazardous at the bottom (soluble, low volatility).

Based on an examination of the hazard factors, the 15 chemicals are grouped into four hazard categories and ranked according to hazard potential. This categorization and ranking is presented in Table 5-5. Chlorine is by far the most hazardous chemical. It not only produced the most casualties at all three spill sites but accomplished this with a relatively small spill, thereby exhibiting a very large specific lethality compared to the other chemicals.

LNG, LPG, and methyl bromide were ranked in the next most hazardous category. They produced significant casualties for all three spill scenarios. Although LNG generally produced more casualties and structural damage than LPG, it did it with a much larger spill (25,000 vs. 10,000 m³). At Perth Amboy the specific lethalties were approximately equal for LNG and LPG, and at Coney Island and Los Angeles the specific lethality for LPG was greater than that for LNG. Because each is ranked higher than the other for one of the two hazard factors, it was felt that a differentiation between the hazard potential of the two chemicals could not be made and they were ranked equally.

TABLE 5-4. Hazard Factors Derived from Simulations

CHEMICAL CHARACTERISTICS	HAZARD TYPE	SPILL SIZE (m ³)	PERTH AMBOY		CONEY ISLAND		LOS ANGELES	
			Total Deaths	Specific Lethality ^a	Total Deaths	Specific Lethality ^a	Total Deaths	Specific Lethality ^a
Insoluble	Chlorine	182	9,350	51.4	75,040	412	18,740	103
	LNG	25,000	1,690	0.07	9,560	0.38	49	0.002
	LPG	10,000	590	0.06	7,640	0.76	175	0.02
	Methyl Bromide	3,000	7,950	2.65	1,090	0.36	48	0.02
	Methyl Chloride	3,000	47	0.016	0	0	0	0
	Vinyl Chloride	6,000	276	0.05	0	0	0	0
Soluble	Ethyl Ether	6,000*	188	0.03	0	0	0	0
	Pentane	4,000	164	0.04	0	0	0	0
	Octane	4,000	0	0	0	0	0	0
	Toluene	4,000	48	0.01	0	0	0	0
Moderate to Low	Ammonia	10,000	1,845	0.2	0	0	0	0
	Dimethylamine	3,000	0	0	0	0	0	0
	Acetaldehyde	3,000	0	0	0	0	0	0
	Acrylonitrile	3,000	0	0	0	0	0	0
High	Propylene Oxide	3,000	0	0	0	0	0	0

^aSpecific Lethality = deaths divided by spill size (fatalities per cubic meter).

*Double tank spill.

TABLE 5-5. Hazard Ranking

HAZARD CATEGORY	CHEMICAL	TYPE OF HAZARD	HAZARD RANK	MAXIMUM FATALITIES	MAXIMUM SPECIFIC LETHALITY	REMARKS
MOST HAZARDOUS (thousands of fatalities at all three scenarios)	Chlorine	T	1	75,040	412	
	LPG	F	2	9,560	0.38	
	LPG	F	2	7,640	0.76	
VERY HAZARDOUS (appreciable deaths under a variety of conditions)	Methyl Bromide	T	2	7,950	2.65	
	Ammonia	T	3	1,845	0.2	
	Vinyl Chloride	F	4	276	0.05	
HAZARDOUS (fatalities only under a narrow range of conditions)	Pentane	F	4	164	0.04	
	Methyl Chloride	F	5	47	0.016	
	Toluene	T	5	48	0.01	
	Ethyl Ether*	F	6	188	0.03	No fatalities with single tank spill
	Octane	F	7	0	0	Very low volatility
RELATIVELY NONHAZARDOUS	Dimethylamine	F	7	0	0	Soluble
	Acetaldehyde	F	7	0	0	Soluble
	Acrylonitrile	T	7	0	0	Soluble
	Propylene Oxide	T/F	7	0	0	Soluble

*Double tank.

Methyl bromide was also given the same ranking as LNG and LPG. It produced appreciably more casualties at Perth Amboy than did LNG or LPG, but the reverse was true for Coney Island. Although the specific lethality was about four times greater for methyl bromide at Perth Amboy than that of LNG and LPG, it was comparable at the other two sites. Considering the fact that LNG and LPG hazards were not maximized,* the larger specific lethality for methyl bromide was not considered significant and methyl bromide was given the same hazard potential ranking as LNG and LPG.

All of the chemicals that resulted in casualties only at Perth Amboy were placed in the next hazard category. Of these, ammonia was clearly the most hazardous due both to the large number of casualties and to the larger specific lethality. Vinyl chloride and pentane, with approximately the same specific lethality and comparable total deaths, were ranked next. Then followed methyl chloride and toluene, whose hazard factors were quite comparable. The last of the chemicals ranked as "hazardous" was ether which did not produce any casualties for a single tank spill, but did for a double tank.

The five chemicals that did not cause casualties for any of the scenarios were ranked as relatively nonhazardous. Since the Perth Amboy scenario was a rather extreme scenario in terms of population proximity and atmospheric stability, the lack of casualties at Perth Amboy indicates that these chemicals will probably not result in acute damage under most large-spill conditions.

In sum, the 15 chemicals were ranked in four major hazard categories and in seven subcategories. The only chemicals that were ranked in the most hazardous or very hazardous categories were insoluble, highly volatile chemicals. The only soluble chemical to be ranked as hazardous was ammonia, for which a large spill was simulated. All other hazardous chemicals were insoluble and moderately to highly volatile. All the relatively nonhazardous chemicals were either insoluble or involatile.

A final comment is made regarding the hazards of toxic versus flammable chemicals. The toxic chemicals in general exhibited the greatest hazard potential (for the insoluble, highly volatile chemicals). The reason for this is that the toxic puff or plume made a long swath through the populated area and many people within this area became fatalities. In the case of the flammable chemicals, only those exposed people in the vicinity of the vapor cloud at the time of ignition became casualties. When ignition occurred, it occurred soon after the vapor cloud reached the shore, and in general only a portion of the cloud was over land at the time. The casualties for LNG and LPG might have been appreciably greater if ignition had been delayed until the vapor cloud covered a more populated region, especially for the Los Angeles simulations where the cells near the shore were relatively unpopulated. However, the one-shot casualty-producing characteristics of the flammable vapor cloud versus the

*Delayed ignition could have produced greater casualties for LNG and LPG.

continuous casualty-producing effects of the toxic vapor cloud, together with the early ignition likelihood of flammable clouds, make the highly flammable chemicals less hazardous than the highly toxic ones. This conclusion is based on direct casualties only, and does not consider the fire damage to structures or the casualties that might occur if a fire storm occurred as a result of widespread ignition. Also, it does not consider evasive tactics which could reduce the toxic casualties significantly at far-field downwind distances. These latter considerations are functions of the effectiveness of civil emergency plans, time of day and day of week, local fire protection availability, and many other variables which are difficult to quantify.

Chapter 6

FILES AND TAPES CREATED UNDER THIS CONTRACT

Two new chemical properties tapes were created in SCOPE-internal (SI) format, in seven-track, 800 BPI, ANSI-labelled format. Their visual serial numbers (VSN's) are S3216 and S26506=KW4942, and they replace S3984 which wore out.

The updated VM was recompiled using the optimizing FORTRAN processor. Both the source code and Phase 1, Phase 2 object modules were written onto a new tape, OS1828. Also recorded on this tape was the entire Chemical Properties file, plus the Default and DPI Values files, to conserve system resources demand. The new tape is a public-access, nine-track, 1600 BPI, labelled tape, VSN=OS1828. A request card for this tape would look as follows:

REQUEST,TAPE,NT,PE,CT=PU,ID=USCG,VSN=OS1828.

The first file on this tape is the updated VM source code (VMSYM or OLDPL); then, in order of appearance, comes the entire Chemical Properties file, the Default Values file, the DPI Table file, the Phase 1 object module, and the Phase 2 object module.

As a backup to this tape, a new VM file set has been catalogued on SCOPE as Cycle 15. Cycle 15 stores USCGVULMODLGO, which contains both updated object modules (ID=USCG) and NEWVMSYM, which contains the updated VM source code (ID=USCG). Public-access tape OS7073* has been created to complement these files; it contains, in the following order, the entire Chemical Properties file, the Default Values file, and the DPI Table file. Jobstream DISPM (Figure 3-1 in Chapter 3) illustrates the tandem usage of OS7073 and USCGVULMODLGO. The total disk storage required for Cycle 15 is 659 SDB's (standard data blocks).** Standard VM run jobstream RUNVM2 (formerly, CHEAPVM) illustrates the usage of tape OS1828; it is listed in Chapter 2 as Figure 2-6. Note that in both jobstreams VM output is directed toward the printers at the Eastern Cybernet Center, 1151 Seven Locks Road, Rockville, Maryland 20854.

Tables 6-1 and 6-2 list the current SCOPE-resident tapes and files, respectively, available under Coast Guard account 57205.

*Nine-track, 1600 BPI, ANSI-labelled.

**There are 1280 characters (6-bit) per SDB.

DESCRIPTION OF THE VULNERABILITY MODEL

Appendix A

DESCRIPTION OF THE VULNERABILITY MODEL

The Vulnerability Model (VM) is a computer simulation which assesses the consequences of hazardous materials spills. When the user specifies the:

- characteristics of the cargo (e.g., chemical composition, size of tank, temperature of cargo),
- size and location of the rupture,
- characteristics of the spill environment (e.g., marine characteristics and weather conditions),
- geographical location of the spill, and
- location and characteristics of the vulnerable resources (people and property) in the vicinity of the spill;

the VM will compute the:

- size and characteristics of the spill,
- disposition of the hazardous material (e.g., mixing, sinking, dilution, vaporization, diffusion, dispersion),
- concentrations and hazardous effects of spilled material as a function of position and time (e.g., toxic concentration and dose, thermal intensity and dose, overpressure), and
- number of people killed and injured and amount and value of property damaged.

The VM simulates two basic types of hazardous chemicals: toxic and flammable. For toxic chemical spills, the VM simulates the development of the spill, the vaporization of the chemical and the formation of a toxic cloud or plume, the movement and dispersion of the cloud, and the acute toxic damage (deaths and injuries) occurring to people residing in the path of the cloud.

For flammable chemicals, the VM computes fire damage to people and property resulting from three types of fire hazards: pool burning, fireball, and flash fire. Pool burning occurs when an immiscible flammable liquid is spilled and catches on fire at the spill site while it is still in the form of a floating pool of liquid.

A fireball occurs when a pressurized gas or highly volatile liquid is ignited as it escapes, bursting the tank and generating a highly combustible mixture of material and air which burns very rapidly and forms a fireball. The fireball hazard is common for incidents involving propane.

Flash fire occurs for volatile chemical spills which do not catch fire at the spill site (due to lack of an ignition source) but form flammable vapor clouds which are blown downwind and are ignited at some distance from the spill site. The flash fire hazard can be the most serious, because it involves the transport of the hazardous material from the spill site to downwind areas that can be much more populated than the spill site. If, at the time of ignition, all of the spilled liquid has not been vaporized, then pool burning occurs in addition to flash fire. Also, the possibility exists that under certain conditions the highly combustible vapor cloud can explode rather than burn. Hence, the VM simulates the explosion of the vapor cloud in addition to flash fire and computes the explosion damage to people and property as well as flash fire damage. The user is cautioned that in all cases involving unconfined flammable vapor clouds, flash fire is much more likely to occur than explosion. However, explosion is included as a worst-case consideration, even though it is recognized to be a remote possibility in most spill situations.

The VM is designed to simulate the consequences of hazardous materials spills at specific ports, harbors, or other marine locations. To do this, the user must specify the location and characteristics of the vulnerable resources in the vicinity of the spill site. This is accomplished by means of a Geographical/Demographical file which divides the area of interest into cells and gives the location, number of people, and number and value of buildings for each cell. In simulating damage, the VM computes the damaging effects such as toxic dose or radiation dose occurring at each cell; converts this to the fraction of people and buildings damaged at each cell, multiplies by the number of people and buildings that exist in each cell; then adds up the damage for all cells.

The VM simulates spills in confined waters as well as open waters. It also considers the effects of tidal or river flows if specified by the user. The VM does not, however, simulate the effects of topography on vapor cloud dispersion; i.e., it assumes that the land, like the water, is flat. The key parameters that determine the vapor cloud dispersion are the wind direction, the wind speed, and the atmospheric stability coefficient.

In application, the VM is one of the key components of the U.S. Coast Guard Risk Management System, a system of analytical models for (1) identifying and assessing the principal spill risks associated with hazardous materials marine transportation and (2) determining the cost benefits of alternative safety regulations or actions which reduce the risks.

The VM is a planning tool and not a quick-reaction model to assist in the response to actual hazardous materials spills. It is to be used in regulatory or safety systems analysis to assist in the design and evaluation of alternative means to reduce the hazards of marine spills. In this type of application, the VM is used to determine the effect on consequences of alternative safety measures and actions. Typical applications are:

- *terminal or facility siting* (evaluation of the relative hazards of alternative sites),
- *facility design* (evaluation of the effect on consequences of alternative safety measures),
- *vessel safety analysis* (evaluation of the effect on consequences of alternative means to reduce spill potential),
- *traffic control systems analysis* (evaluation of the effect on consequences of alternative traffic control schemes),
- *spill response analysis* (evaluation of the effect on consequences of alternative means of spill containment).

Appendix C

DERIVATION OF PROBIT COEFFICIENTS

Appendix C

DERIVATION OF PROBIT COEFFICIENTS

Fourteen toxic chemicals are incorporated in the UIM. These consist of seven chemicals for which probits had been previously derived and seven new toxic chemicals for which probit equations had to be developed. For the previously derived chemicals, all probit equations were reviewed and changes were made where errors were found or where new data could be utilized. For the new chemicals, toxic effects literature was researched and probit coefficients were derived from available dose-response data, using logical extrapolations and inferences where necessary.

The probit methodology is discussed on pages 77 to 90 of Eisenberg et al. (1975) (reference [1] of this report) and can be found in numerous toxicology or mathematical textbooks.

Table C-1 presents the probit coefficients derived for the 14 chemicals. Presented are the concentration exponent (n), the constant (a), and the slope (b) of the probit equation:

$$Pr = a + b \ln \int_{t_e} C^n dt$$

where: Pr = probit value
C = concentration (function of time)
t_e = time of exposure

Also presented are the irritation thresholds.

The dose effects data on which each of the probit derivations is based are summarized in the following paragraphs. Much of the data represents expert judgment of specialists after review of the existing dose-response data for animals and humans.

TABLE C-1

Probit Coefficients for Toxic Chemical Lethality
(concentration in ppm, time in minutes)

Chemical	Exponent of Concentration (n)	Constant (a)	Slope (b)	Irritation Threshold (ppm)
Acrolein	1.00	-9.9315	2.0488	0.26
Acrylonitrile	1.43	-29.4224	3.008	None
Ammonia	1.36	-28.33	2.27	100
Carbon tetrachloride	2.50	-6.29	0.408	None
Chlorine*	2.64	-36.45	3.13	3.4
Hydrogen chloride	1.00	-16.85	2.00	10
Hydrogen cyanide	1.43	-29.4224	3.008	None
Hydrogen fluoride*	1.00	-25.8689	3.3545	32
Hydrogen sulfide	1.43	-31.42	3.008	70
Methyl bromide	1.00	-56.81	5.27	None
Phosgene	1.00	-19.2736	3.6861	5
Propylene oxide	2.00	-7.415	0.509	None
Sulfur dioxide	1.00	-15.670	2.10	5
Toluene	2.50	-6.794	0.408	None

*Injury probits are available for chlorine and hydrogen fluoride only.
The probit coefficients for injuries are as follows:

	<u>Exponent</u>	<u>Constant</u>	<u>Slope</u>
Chlorine	1.00	-2.40	2.90
Hydrogen fluoride	1.00	2.797	2.90

ACROLEIN

The dose-response data used for generating the probit coefficients are presented below. The data were extracted from the table for acrolein on page 88 of Raush et al. (1977) (reference [2] of this report).

% Deaths	Exposure (minutes)	Concentration (ppm)
3	45	14.76
	15	42.18
	5	126.53
50	90	14.76
	45	42.18
	10	126.53
97	90	42.18
	22.5	126.53

ACRYLONITRILE

Acrylonitrile is a liquid; boiling point, 77.3°C; % by weight in saturated air, 14.5; solubility in water, 7.3%.

An unsuccessful search for useful dose-response data was made, and it appears that even a substantial further effort is unlikely to pay off. However, we can make a reasonable estimate of human response to acute exposure at high concentrations because acrylonitrile is toxicologically similar to hydrogen cyanide (HCN), and a similar type of response can be expected. The problem then is to estimate relative numbers.

The complicating factors are:

- HCN gives far from constant effects for a given dose (Ct) over various exposure times; the reason is rapid detoxification to SCN⁻ and presumably acrylonitrile is the same. (See the table in the Hydrogen Cyanide section below, where the LCt_{50}^* for 30 minutes is 10 times that for 0.5 minute.)
- The CN of acrylonitrile may not be as immediately available in vivo (though the literature is unclear on this), and so the detoxification may have more opportunity to occur. (We propose to ignore this: we have no way to allow for it, and not doing so will avoid possible underestimation of casualties.)

* LCt_{50} is the dose (concentration times time) which results in 50% deaths.

Lethal exposures to acrylonitrile from Patty (1962) are:

Rat	1.38 mg/liter
Rabbit	0.56 mg/liter
Cat	0.46 mg/liter
Guinea pig	1.25 mg/liter
Dog	0.18 mg/liter

These are not to be regarded as LC_{50} * values and times are lacking or not explicit, so we have no LCT values. Note that the dog is most sensitive, as for HCN. Omitting the dog, we have a value of roughly 1 mg/liter or $1,000 \text{ mg m}^{-3}$. This is equivalent to about 500 mg/liter of HCN (on an equal CN basis). The concentration of HCN estimated for LCT_{50} in man is:

Time (minutes)	Concentration (mg m^{-3})
1	3,406
3	1,467
10	607
30	687

We don't know the times for acrylonitrile, but they are very probably more than a few minutes (and this is the true range of interest for the VM), so for the derivation of the probit coefficients for acrylonitrile we used the HCN dose-response data. (Acrylonitrile should, however, be significantly less of a hazard because its vapor pressure is lower.)

ANNEXIA

The best estimate of dose-response and its time dependence is presented in the following table which is extracted from Table 6-4 (page 86) of reference [1] of this report.

% Deaths	Exposure Time (minutes)	Concentration (ppm)
3	45	1,750
	15	3,250
50	90	1,750
	45	3,250
97	90	3,250

* LC_{50} is the concentration that results in 50% deaths. Usually a time is specified when LC_{50} is given.

CARBON TETRACHLORIDE

The probits for carbon tetrachloride are derived from dose-response data presented below and extracted from pages 81 and 82 of Rausch et al. (1977).

% Deaths	Exposure Time (minutes)	Concentration (ppm)
5	5	6.67×10^3
	15	4.45×10^3
	30	3.18×10^3
	60	2.54×10^3
50	5	33.4×10^3
	15	22.25×10^3
	30	15.9×10^3
	60	12.7×10^3

CHLORINE

This is definitely not a Haber's Law toxicant. As concentration increases, the LCt₅₀ decreases. Best estimates of time relationships are:

Time	LC50 (ppm)	LCt50 (ppm min)
Several hours	20	3,650
60 minutes	33	1,980
10 minutes		600

The dose-response would be more or less the same at the various exposure times. The best estimate of dose-response is:

% Lethality	Relative Dose
10	0.66
20	0.76
50	1.00
80	1.30
90	1.50

The basis for the injury probit coefficients is given on page 87 of Eisenberg et al. (1975).

HYDROGEN CHLORIDE

The probits for hydrogen chloride were derived from the dose-response data below extracted from Table 5-4 of Rausch et al. (1977).

% Fatalities	Exposure Time (minutes)	Concentration (ppm)
3	45	302
	15	906
	2.5	>1,342
50	90	302
	45	906
	10	>1,342
97	90	906

HYDROGEN CYANIDE

The following estimates of toxicity for man are from McNamara (1976), and may be confidently used as the best and most authoritative estimates available, and were used to derive the probit coefficients after conversion to ppm.*

Lethal Dosages for Man in mg min m^{-3}

Exposure Time (minutes)	% Deaths					
	1	16	30	50	84	99
0.5	1,177	1,606	1,791	2,032	2,552	3,480
1	1,930	2,632	2,937	3,404	4,183	5,705
3	2,546	3,473	3,874	4,400	5,519	7,526
10	3,888	5,302	5,916	6,072	8,426	11,491
30	11,992	16,355	18,247	20,632	25,991	35,443

McNamara arrived at these estimates by the same sort of method that we have used previously. Data for various animals (Barcroft, 1931) were analyzed to get dose-response regression lines, and the susceptibility of man (i.e., absolute value of LCt_{50}) was assumed to be similar to that of the resistant goat or monkey. (This was supported by, inter alia, Barcroft's

*To convert mg min m^{-3} to ppm min, multiply by 0.906.

exposure of himself and a dog in the same chamber.) Data for the mouse were used to estimate relative LC_{50} values for various times.

There is no basis for estimating incapacitating casualties, which are likely to be rare. A few might suffer serious brain damage or persistent mental impairment (there is some evidence that Barcroft was afflicted for about a year), but there is no quantitative information and they would certainly be a small minority at most. (Barcroft's self-exposure was probably between $825 \text{ mg min m}^{-3}$ and $1,032 \text{ mg min m}^{-3}$.)

HYDROGEN FLUORIDE

Response to this toxicant obeys Haber's Law, i.e., effect is a function of dosage only and not a function of time and concentration. The dose-response data upon which the prohibit coefficients are based are presented in the following table as extracted from data on page 37 of Rausch, Tsao and Rowley (1977) (reference [3] of this report).

Deaths	Dose (ppm min)
100	24,450
95	19,560
50	12,255
5	7,335

HYDROGEN SULFIDE

No data suitable for calculating dose-response regression for hydrogen sulfide (H_2S) has been found. However, it appears that the same dose-response as for hydrogen cyanide (HCN) is unlikely to be seriously in error. Evans (1967) stated:

"There is a close similarity between the actions of HCN and H_2S on enzyme systems; both act as inhibitors of catalases and peroxidases (which all contain iron), and of dopa oxidase, succinic dehydrogenase, carbonic anhydrase, dipeptidases and benzamidase. HCN is known to combine with the iron in cytochrome A; (Keilin and Hartree, 1939); H_2S probably acts similarly, and has also been shown to inhibit, and at about the same molar concentrations, other systems connected with tissue oxidations, such as the CoH_2 oxidase system (Slater, 1958)."

The most conspicuous effects of exposure to high concentrations are loss of consciousness and respiratory paralysis. Immediate first aid to restore respiration is effective. Victims who recover naturally or with medical aid seldom show any lasting harm unless hypoxia has damaged the

cerebral cortex. The gases are similar also in being quite rapidly detoxified in the body. For our purposes, this means that the simple dosage-response relation of Haber's Law does not apply. The gases differ in that H_2S has a stronger odor, particularly offensive at low concentrations (but at all concentrations, especially higher, olfactory fatigue is rapid), and it is also more irritant, so that its effect on the respiratory mucosa and eye dominates the picture at lower concentrations; eye effects may persist for some days.

The close similarity of the two toxicants, HCN and H_2S , suggests that the slope of the regression should be similar, and that the time-dependence of LCt should also be similar; the evidence is that detoxification occurs at a similar rate. We need therefore to check that lethal exposures are estimated to be of the same order.

Patty (1963) gives the "dangerous" exposure for 0.5 to 1 hour as 560 to 980 $mg\ m^{-3}$; i.e., a Ct of 34,650. RTECS (1977; apparently quoting Henderson and Haggard, but no reference is given) quotes an $LCLo$ (least lethal concentration found) of 860 $mg\ m^{-3}$ for 30 minutes ($CT = 25,200$). NIOSH (1977) gives a concentration of 1,400 $mg\ m^{-3}$ as "rapidly" fatal, which may be supposed to mean of the order of 15 minutes ($CT = 21,000$). An estimate can be made from the well-known Poza Rica disaster (quoted in NIOSH, 1977), in which exposure for less than 20 minutes to an estimated 1,400 to 2,800 $mg\ m^{-3}$ killed 22 and hospitalized an additional 307; residual nervous damage was reported in four. (The Ct , admittedly uncertain, may have been $2,100 \times 15 = 31,500\ mg\ min\ m^{-3}$.) Deaths were delayed in a few: four at 2 hours, four at 6 hours, one at 24 hours, one each on the 2nd, 5th, 6th, and 9th days. "About half the domestic animals...died", mostly during the acute phase. NIOSH (1977) also quotes data for monkeys, including one unconscious and needing artificial respiration after 25 minutes at 700 $mg\ m^{-3}$ ($Ct = 34,300$). Poda (1966) reported 123 cases of H_2S poisoning at an industrial plant. There were no fatalities but 25 became unconscious. Stay in hospital/infirmary was:

- 25: 1 hour
- 62: 1 to 4 hours
- 11: 4 to 12 hours
- 6: >12 hours.

The estimates of Ct for fatality, despite their unreliability, encourage the use of McNamara's HCN estimates for want of a better solution. Compare, for example, his LCt_{50} (30 minutes) of 20,632 $mg\ min\ m^{-3}$ with the H_2S estimates. It appears that H_2S is a little less toxic; thus, probit coefficients were derived by doubling the HCN figures and converting them to ppm.

METHYL BROMIDE

All the evidence points to the fact that this is a strict Haber's Law toxicant over quite a wide range of concentrations. On the basis of dose-response data for several species including man, the best estimate for lethal dose in man is:

$$LCt_{50} = 125 \times 10^3 \text{ ppm min.}$$

The slope of the dose-response relationship is based on the data developed in Rausch et al. (1977), page 89:

Lethality	Concentration (ppm)
99	184.3×10^3
90	164.4×10^3
50	125.8×10^3
10	98.4×10^3
1	77.2×10^3

PHOSGENE

The probit coefficients for phosgene were derived from the following data extracted from Rausch et al., page 89:

Lethality	Dose (ppm min)
95	1,052
50	765
15	526

PROPYLENE OXIDE

Propylene oxide is a liquid, with a boiling point of 34.2°C.

Epoxides of low molecular weight are primarily irritants with a mild depressant effect on the central nervous system. As alkylating agents, they have a radiomimetic effect.

Data in Patty show a considerable influence of time on effective concentration. An example from data on minimum intensity of exposure to

cause death in all animals:

Time (minutes)	Concentration (mg m ⁻³)	Dosage (mg min m ⁻³)
6	95,000	570,000
60	33,300	2,000,000
600	9,500	5,700,000

This time-dependence of dosage is not unlike HCN. These data were used to derive the exponent of the concentration.

The data also show that propylene oxide is not very toxic. With an LC₅₀ of the order of 1×10^5 mg min m⁻³, it is similar to carbon tetrachloride and methyl bromide. The type of dose-dependence is however much more like that of CTC than MeBr (which has a Haber-type dependence on dosage). Despite the considerable differences in toxicology, we think that the CTC dose-response data should serve adequately for derivation of propylene oxide probit coefficients.

SULFUR DIOXIDE

This gas has been studied very extensively in chronic, low-level exposure, because of its prominence in air pollution monitoring and control. (It is, however, probably a proxy for sulfates that are the actual etiologic agents in epidemiological studies.) Low-level human exposure shows it to be highly irritant. Henderson and Haggard (1943), for example, give:

ppm	mg m ⁻³	
8-12	21-31	Threshold for throat irritation
10	26	Maximum allowable for long exposure
20	52	Threshold for immediate eye irritation and coughing
50-100	130-260	Maximum for 1/2 to 1 hour
400-500	1040-1300	Dangerous for short exposure

Johnstone and Miller (1960) say that "intolerable irritation and laryngospasm" occur at 2,000 ppm (5,200 mg m⁻³) and laryngeal edema follows. NIOSH (1974) says that in catastrophic exposure, asphyxiation is probable; if the victim survives, chemical bronchopneumonia may develop and may be fatal after some days. (A man exposed for 15 to 20 minutes died 17 days later.) Cynomolgus monkeys exposed to 200 to 1,000 ppm (520 to 2,600 mg m⁻³) for one hour (Ct = 31,200 to 156,000 mg min m⁻³) suffered permanent deterioration of respiratory function; they had been under chronic, low-level exposure for 30 weeks.

We have here a case unlike any previous one studied for the VM and unfortunately insufficient data to support reliable estimates. The strongly irritant properties are not unlike those of NH_3 or HCl , or even of Cl_2 ; and the persistent, possibly fatal pneumonia reminds one of Cl_2 . But it is clearly not so dangerous as Cl_2 in doses below the asphyxiating level.

The best estimate for dose-response is that it is similar to HCl . Thus, the probits for sulfur dioxide were derived assuming dose-response is identical to HCl (in mg min m^{-3}).

TOLUENE

Toluene is a liquid; boiling point, 110.6°C ; ρ in "saturated" air, 3.94. It is a powerful narcotic and a central nervous system depressant.

Some data from Patty and other sources are shown below:

Minimum for given effect in animal experiment (mice)

Prostration	10,000 - 12,000 mg m^{-3}
Death	30,000 - 45,000 mg m^{-3} [No times given.]

Rats: 18 days of 4-hour exposure

4,700 mg m^{-3}	No deaths
15,000 mg m^{-3}	Deaths [No numbers of deaths.]

Volunteers: at 8 hours unless stated

750 mg m^{-3}	Mild weakness, paresthesia
1,500 mg m^{-3}	Same, plus mental confusion
2,250 mg m^{-3}	Nausea, dizziness, staggering; mental confusion in 3 hours
3,000 mg m^{-3}	Incoordination at 3 hours

These show incapacitation at $2,250 \times 8 \times 60 = 1,080,000 \text{ mg min m}^{-3}$ to $3,000 \times 8 \times 60 = 1,440,000 \text{ mg min m}^{-3}$.

Rats survived

37,600	20 min = 752,000 mg min m^{-3}
75,200	60 min = 4,512,000 mg min m^{-3}

Rats

18,750 $\times$ 150 min = 2,812,500 mg min m^{-3} were completely narcotized. Daily exposure (time?) to 3,760 - 7,520 mg m^{-3} caused incapacitation.

These observations can be compared with those used for CCl_4 in developing dose-response for carbon tetrachloride. Using the data from 10- to 30-minute exposures only, the earlier report shows:

Harassment (dizziness, etc.) at 39,000 to 150,000 mg min m^{-3} ;
 Dangerous at 438,000 to 8,190,000 mg min m^{-3} ;
 Lethal at 2,438,000 mg min m^{-3} and up.

These are in the same ballpark as the toluene data and the two chemicals are somewhat alike (as regards acute toxicity; not so alike for chronic exposure). We believe the CTC equation is adequate for toluene.
