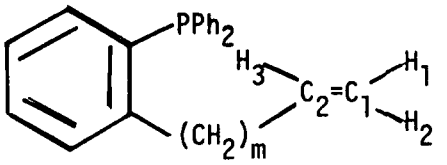
## ABSTRACT

Reactions of [hyper-closo-2-$R^1$-3-$R^2$-6,6-$(PPh_3)_2$-6,2,3-$RuC_2B_7H_7$](I) with (o-styryl)diphenylphosphine ($R^{1,2}$=H,$CH_3$; $R^1$=H,$R^2$=Ph), (o-allylphenyl)diphenylphosphine($R^{1,2}$=H,$CH_3$) and $Ph_{3-n}P(CH_2CH_2CH=CH_2)_n$(n=1,2; $R^{1,2}$=$CH_3$) afforded the 16e$^-$ ruthenacarborane complexes [hyper-closo-RuL($C_2B_7H_7R^1R^2$)] (IIa-g), in which the alkenyl phosphine (L) functions as a bidentate ligand. The crystal structure of [2,3-$(CH_3)_2$-6-$(CH_2$=$CHCH_2C_6H_4Ph_2P)$-6,2,3-$RuC_2B_7H_7$](IId) was determined from three-dimensional X-ray counter data. The complex crystallizes in the monoclinic system, space group $P2_1/c$ with a=11.740(3) Å, b=15.185(5) Å, c=21.748(7) Å, $\beta$=137.43(2)$^o$ and Z=4. Refinement of 4168 independent reflections with $I>3\sigma(I)$ led to a final value of R=4.0%. The structure of this complex may best be described in terms of a $C_2B_7$ fragment of arachno-geometry which occupies nine vertices of an eleven-vertex octadecahedron with a ruthenium atom in a "non-vertex" position and within bonding distance of six atoms in the open face. The observed distortion from the common ten-vertex bicapped square antiprismatic structure is thought to be a result of the perturbation of the polyhedral skeletal bonding induced by the sixteen-electron $Ru^{II}$ center. Reaction of (IIb) with carbon monoxide displaced the coordinated alkenyl side-chain to yield the 18e$^-$ $Ru^{II}$ complex [closo-6,6-$(CO)_2$-6-L-6,2,3-$RuC_2B_7H_9$](IIIa){L=(o-allyphenyl)-diphenylphosphine}.

Reactions of $Ph_{3-n}P(CH_2CH_2CH=CH_2)_n$(n=1,2) with [hyper-closo-6,6-$(PPh_3)_2$-6,2,3-$RuC_2B_7H_9$] produced the fluxional complexes [closo-6,6-$L_2$-6,2,3-$RuC_2B_7H_9$] (IVa-b) which exhibit butenyl side-chain exchange and undergo closo-hyper-closo equilibria as evidenced by variable temperature multinuclear FTNMR spectroscopy. The reactions of (IVa-b) with carbon monoxide are also discussed.

As part of our study of metallocarborane-catalyzed homogeneous hydrogenation and isomerization of alkenes,[1,2] we have attempted to isolate or detect possible intermediates in the catalytic cycle.[3] Although we have previously noted that the unsaturated ruthenacarboranes $[Ru(PPh_3)_2(C_2B_nH_{n+2})]$ (n=7[4],9[2]) react with electron-deficient alkenes we were unable to isolate alkene-metallocarborane complexes because of their instability. To overcome this difficulty, the potentially chelating alkenyl phosphines[5] (o-styryl)-diphenylphosphine (SP),[6] (o-allylphenyl)diphenylphosphine (AP)[7] and $Ph_{3-n}P-(CH_2CH_2CH{=}CH_2)_n$ (n=1, but-3-enyldiphenylphosphine {MBP}; n=2, di(but-3-enyl)phenylphosphine {DBP})[8] were used to prepare derivatives of the above ruthenacarboranes. This paper describes the synthesis and properties of such alkenyl phosphine complexes prepared from $[2\text{-}R^1\text{-}3\text{-}R^2\text{-}6,6\text{-}(PPh_3)\text{-}6,2,3\text{-}RuC_2B_7H_7]$ (Ia-c; $R^{1,2}$=H or Me; $R^1$=H, $R^2$=Ph).



m = 0, SP
m = 1, AP

The complex $[2,3\text{-}(CH_3)_2\text{-}6\text{-}(CH_2{=}CHCH_2C_6H_4Ph_2P)\text{-}6,2,3\text{-}RuC_2B_7H_7]$ was the subject of a single crystal X-ray diffraction study, which revealed several interesting structural features. Unlike previously isolated metal complexes derived from the 1,3-dicarba-arachno-nonaborane(13) cage system,[9] this complex has the metal within bonding distance of all six atoms in the open face. Distortion from the standard closo-structure was anticipated as this n-vertex polyhedron contains only 2n skeletal bonding electrons, as does [hyper-closo-$\{(\eta^5\text{-}C_5H_5)Fe\}_2C_2B_6H_8$].[10]

The complexes [closo-6,6-$L_2$-6,2,3-$RuC_2B_7H_9$] (L=MBP or DBP) were the subject of a variable temperature multinuclear FTNMR study wich demonstrated the existence of two types of exchange processes. The first involves exchange of metal-coordinated and uncoordinated butenyl side-chains, while the second involves phosphine ligand dissociation with concomitant polyhedral rearrangement (closo-hyper-closo equilibrium).

## RESULTS AND DISCUSSION

### Synthesis, Reactivity and Spectral Data for Hyper-closo Ruthenacarboranes

The reactions of $[Ru(PPh_3)_2(C_2B_7H_7R^1R^2)]$ with SP or AP ($R^{1,2}$=H or Me; $R^1$=H , $R^2$=Ph SP only) and MBP or DBP ($R^{1,2}$=Me) afforded the deep-red crystalline compounds $[RuL(C_2B_7H_7R^1R^2)]$(IIa-g; L = alkenyl tertiary phosphine; See Table 1). Elemental analyses and mass spectral data agreed with the proposed empirical formulae for IIa-g. Except for L=DBP(IIg), the infrared spectra of IIa-g contained no bands near 1630 $cm^{-1}$ due to $\nu_{C=C}$for a free alkene group. Instead, medium to weak bands at 1470 and 1260 $cm^{-1}$ assignable to a coordinated alkene were observed.[11,12]

The NMR spectra of complexes IIa-g were also consistent with coordination of the alkene side-chain to the ruthenium atom. The alkenyl proton resonances were shifted 1.4 to 3.7 ppm upfield from the corresponding resonances of the free ligand. With $^{31}P$-decoupling, the alkenyl proton resonances of $[Ru(SP)(C_2B_7H_9)]$ (IIa) appeared as a first-order AMX spin system with no detectable geminal coupling between $H_1$ and $H_2$ (Figure 1). These alkenyl signals were assigned by assuming that the magnitudes of trans-

Figure 1

vicinal couplings ($J_{2-3}$) remain larger than the corresponding cis-couplings ($J_{1-3}$) upon complexation of the alkenyl group to ruthenium. The alkenyl coupling constants of IIa-g were smaller than those in the free ligands[8,13,14] and similar to those found in other transition metal complexes containing chelating alkenyl phosphines or arsines.[13-16] In the $^{13}C\{^1H\}$ NMR spectra, the alkenyl carbons of IIa-g appeared approximately 42 to 60 ppm upfield from those of the free phosphine.[17] Off-resonance decoupled and proton-coupled spectra (for sufficiently soluble compounds) were used to assign these resonances.

The $^{11}B$ NMR spectra of compounds IIa-g were consistent with the presence of an asymmetric carboranyl ligand (see Figure 2). Those of IIf-g

Figure 2

contained seven doublets ($J_{B-H} \tilde{=} 120$ Hz) of roughly equal areas and the spectra of IIa-e were similar, but not as well resolved. As in the parent, $[Ru(PPh_3)_2(C_2B_7H_7R^1R^2)]$,[4] the complexes IIa-g exhibited resonances at about

107 ppm (relative to external $BF_3 \cdot OEt_2$) suggesting that the basic closed polyhedral ruthenacarborane structure was retained in the phosphine metathesis reaction. The $^1H$ NMR spectra of IIc-d showed two singlets due to two non-equivalent cage-methyl groups, while those of IIa-b contained only one carboranyl C-H singlet, the other carboranyl C-H signal presumably being obscured by the aromatic resonances in the 2.7-3.2 $\tau$ range. This notion is supported by the $^{13}C\{^1H\}$ NMR spectrum of IIb which exhibited two broad singlets (ca. 50 Hz halfwidths) at 106.3 and 122.2 ppm due to the two carboranyl carbon atoms. The other complexes either showed only one cage-carbon resonance (the second resonance is presumably buried under the aromatic carbon peaks), or were not sufficiently soluble to yield observable cage-carbon peaks. Cage-bonded methyl signals were not observed in the $^{13}C$ NMR spectra of IIc-d and may be too broad to detect at ambient temperature.[18,19]

The spectral data presented for IIa-g are consistent with the alkenyl phosphines acting as bidentate ligands. Since complexes IIa-g are electronically and somewhat coordinatively unsaturated, the two alkenyl groups of the ligand di(but-3-enyl)phenylphosphine could conceivably coordinate to the ruthenium atom.[20] However, the infrared, $^1H$ and $^{13}C$ NMR spectra of IIg showed the presence of both free and coordinated butenyl side-chains. The $^1H$ NMR spectrum was essentially temperature-invariant over the range -50 to 40°C, ruling out an equilibrium between free and coordinated alkene.[21] Steric hindrance and/or the additional metal-cage bonding interactions may prevent both butenyl side-chains from bonding to the ruthenium atom simultaneously.

Complexes IIa-g were air-stable in the solid state, but decomposed slowly in air-saturated solutions. They did not react with hydrogen (1 atm) or dry hydrogen chloride and complex IIa was an ineffective catalyst for alkene hydrogenation under mild conditions. No reduction of the alkenyl side-chain[21,22] of IIa was discernible even after several days in benzene solution under 1 at-

mosphere pressure of hydrogen.

Treatment of IIb with carbon monoxide rapidly produced a yellow complex with empirical formula $[Ru(CO)_2(L)(C_2B_7H_9)]$(IIIa; L=AP). The $^1H$ NMR spectrum of IIIa indicated that the allyl moiety is not coordinated to the metal atom. The carboranyl C-H resonances were not located, but the $^{11}B$ NMR spectrum of IIIa was almost identical to that of the complex [closo-6,6-$(CO)_2$-6-$PPh_3$-6,2,3-$RuC_2B_7H_9$][4] suggesting that the two $Ru^{II}$complexes are isostructural.

Complex IIIa and its $PPh_3$ analog are isoelectronic with $[H(PPh_3)_2MC_2B_7H_9]$ (M=Rh,Ir)[4] and $[\{(\eta^5\text{-}C_5H_5)Co\}_2C_2B_6H_8]$,[23] and they presumably possess bicapped square antiprismatic structures, consistent with their formulation as saturated, ten-vertex closo polyhedra.[24] Complexes IIa-g and $[(PPh_3)_2RuC_2B_7H_9]$,[4] however, are unsaturated complexes, all of which exhibit a low-field $^{11}B$ NMR resonance at about 105 ppm and are isoelectronic with $[\{(\eta^5\text{-}C_5H_5)Fe\}_2C_2B_6H_8]$, the structure of which has been determined.[10] Nishimura has recently proposed[25] that the structure of $[\{(\eta^5\text{-}C_5H_5)Fe\}_2C_2B_6H_8]$ can be rationalized in terms of a "hyperpolyhedral" metal-metal bond between the two $17e^-Fe^{III}$ centers of the cluster. In order to resolve this question by determining if an isoelectronic, unsaturated, monometallic ten-vertex cluster is, in fact, isostructural, an X-ray diffraction study of IId was undertaken.

The Molecular Structure of [Hyper-closo-2,3-$(CH_3)_2$-6-$(CH_2\overset{\downarrow}{=}CHCH_2C_6H_4Ph_2P)$-6,2,3-Ru-$C_2B_7H_7$], IId.

Intramolecular distances and their estimated standard deviations are listed in Table VI. Average bond lengths are collected in Table VII. Bond angles and their associated estimated standard deviations are listed in Table VIII. The structure of [2,3-$(CH_3)_2$-6-$(CH_2\overset{\downarrow}{=}CHCH_2C_6H_4Ph_2P)$-6,2,3-$RuC_2B_7H_7$] is shown in Figure 2, together with the numbering system employed.

The structure of this compound may be described in terms of a $C_2B_7H_7Me_2$ fragment of arachno geometry which occupies 9 vertices of an 11-vertex octadecahedron. The ruthenium atom occupies a position between the two empty vertices and is bound to the four boron atoms and two carbon atoms of the chair-shaped six-atom open face.

The ruthenium atom is thus bound to B(10), B(9), B(7), C(2), C(3), and B(1) of the carborane cage and to P, C(28) and C(29) of the (o-allyphenyl)diphenylphosphine ligand. The polyhedral carbon atoms occupy positions 2 and 3 in the fragment and are formally five coordinate. The structure of $[6,6\text{-}(PPh_3)_2\text{-}6,2,3\text{-}RuC_2B_7H_9]$[4] is probably similar with the ruthenium atom bonded to all six atoms in the open face (vide infra).

The ruthenium to cage distances can be compared to those in $[2,2\text{-}(PPh_3)_2\text{-}2,2\text{-}H_2\text{-}2,1,7\text{-}RuC_2B_9H_{11}]$ which range from 2.22(2) Å to 2.32 (2) Å for the five atoms of the carborane open face.[2] However, in the title compound, Ru-B distances involve bonds to boron atoms of different coordination numbers; Ru to 6-coordinate boron B(7), B(9), and B(1) are 2.466(5), 2.340(5), and 2.488(5) Å, respectively, and Ru to 5-coordinate B(10) is 2.023(5) Å. A similar change in Fe-B bond lengths is noted in a compound with comparable cage geometry, [hyper-closo-1,6-$(\eta^5\text{-}C_5H_5)_2$-1,6,2,3-$Fe_2C_2B_6H_8$].[10]

As expected, the polyhedral carbon atoms occupy nonadjacent positions in this compound; they occupy two of the three low-coordinate positions and are related by a noncrystallographic mirror plane through Ru, B(10), B(8) and B(1). Variations from mirror symmetry are within three standard deviations in related bond distances with the exception of B(1)-C(3) and B(1)-C(2), Ru(6)-C(2) and Ru(6)-C(3), and Ru(6)-B(7) and Ru(6)-B(9). Two of these exceptions can be explained by trans-influence.[26] The phosphorous atom is trans- to B(9) and C(28)=C(29) is trans-to C(3). Ru-C(3) is significantly longer than Ru-C(2) and Ru-B(9)is significantly shorter than Ru-B(7).

Unlike [1,6-$(\eta^5\text{-}C_5H_5)_2$-1,6,2,3-$Fe_2C_2B_6H_8$], boron-boron distances and carbon-boron distances within the polyhedron do not reflect the coordination of the various atoms; the shortest boron-boron distance,B(4)-B(5)=1.743 Å, is between two 6-coordinate boron atoms, and the longest distances,B(1)-B(4),B(1)-B(5) and B(8)-B(9),1.814, 1.820, and 1.814 Å, respectively, are also between two 6-coordinate boron atoms.

In general, the bond lengths and angles within the $C_2B_7$ fragment correlate well with the analogous bonds in arachno-$C_2B_7H_{11}Me_2$.[27] The largest deviation is found for B(7)-C(3) and B(9)-C(2). The corresponding distances in the arachno compound are 0.13 Å longer than those in the metallocarborane.

B(9), C(3), P, and the midpoint of C(28)=C(29) are in a square planar conformation about Ru and C(28)=C(29) is nearly perpendicular to this plane. The Ru-P distance of 2.418(1) Å is within the range of distances found for ruthenium bonded to phosphines, but is longer than those found in [2,2-$(PPh_3)_2$-2,2-$(H_2)$-2,1,7-$RuC_2B_9H_{11}$] (2.342(4) and 2.301(4) Å).[2] The longer bond in the title compound may be due to the bulky phosphine ligand with its allyl group. The Ru-C distances of 2.167(4) and 2.191(4) Å are well within the range of distances for Ru π-bonded to an alkene.

Angles and distances involving the phosphorus atom are unexceptional. Although the phenyl ring of the o-allylphenyl moiety is planar, the dihedral angle C(27)-C(26)-C(21)-P is 4.4° and C(27), C(28), H(28), C(29), H(291) and H(292) are not coplanar. The linkage C(27)-C(28) is a normal single bond (1.5306(6) Å) and the distance C(28)-C(29) (1.406(7) Å) is within the range for π-bonded C=C distances. The distance of 1.498(6) Å for C(26)-C(27) and distances and angles in the phenyl ring are not unusual.

The only intermolecular distance less than 2.5 Å is between H(292) and H(513) and is 2.44 Å. Only two nonhydrogen-hydrogen intermolecular distances are less than 3.0 Å and they are between phenyl carbon atoms and a phenyl hydrogen atom and a methyl hydrogen atom, respectively; each distance is 2.96 Å.

The polyhedral geometry of the title compound is significantly different from the bicapped square antiprism found for ten-vertex closo-borane species such as $(B_{10}H_{10})^{2-}$ [28] and $[(C_5H_5)_2Co_2C_2B_6H_8]$ [23] but is very similar to $[(C_5H_5)_2Fe_2C_2B_6H_8]$ [10] and does adopt a fully triangulated closed polyhedral structure. If the title compound was constrained to have the bicapped square antiprism form, a new bond would be needed between C(2) and C(3) and the Ru-B(1) bond would be broken. Then B(1) would be in a lower coordinate position and C(2) and C(3) would be located in 6-coordinate positions.

The structures of the two hyper-closo ten-vertex metallocarboranes mentioned above also do not correspond to the predicted capping of the closo nine-vertex tricapped trigonal prism[29-31] but are instead a result of completely capping the six-membered open-face of the arachno $C_2B_7$ fragment, presumably to compensate for the electronic unsaturation of the metal center.

## Synthesis, Reactivity and Variable Temperature Multinuclear FTNMR Studies of Closo-Ruthenacarboranes

Complex [6,6-$(PPh_3)_2$-6,2,3-$RuC_2B_7H_9$](Ia) reacted with MBP and DBP to produce yellow complexes with empirical formulae [$RuL_2C_2B_7H_9$] (IVa-b; L=MBP and DBP, respectively). The infrared spectra of IVa-b in the solid state contained both free and coordinated butenyl absorptions.[12] Solutions of IVa in toluene or dichloromethane were red at or above room temperature and the solution infrared spectrum in dichloromethane at 22°C exhibited two additional peaks assignable to a coordinated butenyl side-chain at 1325 and 1285 $cm^{-1}$ along with those at 1630(free), 1300 and 1250 $cm^{-1}$(coordinated) observed in the solid state spectrum.[35]

Complex IVb did not yield red solutions until the temperature was above about 60°C. As the ligand cone angle[36] of MBP (140°) is larger than that of DBP (135°) it was presumed that phosphine ligand dissociation occurs to yield the unsaturated, red [hyper-closo-$LRuC_2B_7H_9$] species. This proposal was supported by the observation of a low-field $^{11}B$ NMR resonance at 107.5 ppm in a $d_2$-dichloromethane solution of IVa at 44°C, which was absent at -40°C. In addition, while treatment of IVb with carbon monoxide yielded [closo-$(CO)L_2RuC_2B_7H_9$] in high yield, the yield of the analogous monocarbonyl complex of IVa decreased with increasing temperature due to the formation of the dicarbonyl complex [closo-$(CO)_2LRuC_2B_7H_9$] (vide infra).

The variable temperature $^{31}P\{^1H\}$ FTNMR spectrum of IVa in dichloromethane shown in Figure 3 indicated that the [closo-$L_2RuC_2B_7H_9$] species which predominates

Figure 3

at low temperatures is itself fluxional. At -73°C the spectrum consisted of a doublet for the chelated alkenyl phosphine ligand[12,37] at 68.5 ppm ($^2J_{P-P}$= 32 Hz) and a doublet for the unidentate phosphine ligand at 47.2 ppm. As the temperature was raised, these resonances broadened, but before coalescence was attained, phosphine dissociation started to occur, as evidenced by the change in chemical shift of the unidentate phosphine ligand towards the free ligand limit. The spectrum at 60°C in 10% $C_6D_6$-$C_6H_5CH_3$ represented the high-temperature limit and exhibited a singlet at 49.8 ppm for the [hyper-closo-L $RuC_2B_7H_9$] species and a singlet at 15 ppm for the free alkenyl phosphine ligand.[8] The presence of two exchange processes was more evident in the variable temperature $^{31}P\{^1H\}$-FTNMR spectra of IVb in dichloromethane, as the temperature domains for the two processes were not overlapping. Thus, at -8°C, coalescence of the two inequivalent phosphorus nuclei occurred cleanly and the change in chemical shift of the unidentate phosphine ligand did not begin until above 27°C. (Figure 4)

Figure 4

The variable temperature $^1H$ and $^{13}C\{^1H\}$ FTNMR spectra of IVa were also complicated due to the overlap of the temperature domains of the two dynamic processes. At -78°C the $^{13}C\{^1H\}$ FTNMR spectrum in dichloromethane exhibited free alkenyl carbons at 138.4 and 115.3 ppm, coordinated alkenyl carbons at 79.3 and 58.5 ppm and carboranyl carbons at 72.7 and 41.2 ppm.[38] Broad, free alkenyl carbon resonances were observed at -23°C and at 27°C the only resonances observed were due to exchange-averaged phenyl and methylene carbons of the alkenyl phosphine ligand. The $^1H$ FTNMR spectrum of IVa in $d_2$-dichloromethane at -68°C consisted of three broad resonances at 5.39, 5.78 and 6.11 τ, in addition to three resonances at 4.34, 5.09 and 5.16 τ which can be assigned to the coordinated and free alkenyl protons of

butenyl side-chains, respectively.[16] At -38°C these signals broadened and at 33°C only one set of three alkenyl protons was observed, suggesting that the low temperature exchange process is due to exchange of free and coordinated butenyl side-chains,[21] as depicted in Figure 5.

Figure 5

The variable temperature $^{1}H$ and $^{13}C\{^{1}H\}$ FTNMR spectra of IVb in dichloromethane were more informative, although the presence of three inequivalent butenyl side-chains at the low temperature limit led to overlapping resonances and precluded complete spectral assignments. The $^{13}C\{^{1}H\}$ FTNMR spectra are shown in Figure 6.

Figure 6

At -83°C three sets of alkenyl carbons were observed at 142.3 and 119.2 ($C_2'$ and $C_1'$), 138.5 and 115.6 ($C_2$ and $C_1$) and 74.8 and 52.5 (coordinated $C_2'$ and $C_1'$), where the primed carbons refer to those butenyl side-chains attached to the chelating phosphine ligand. The carboranyl carbons were observed at 75.9 and 39.2 ppm.[38] At -23°C only the $C_1$ and $C_2$ alkenyl carbon resonances were observed and at 27°C, again, only the exchange-averaged phenyl and methylene carbon resonances of the alkenyl phosphine ligand were present. The $^{1}H$ FTNMR spectra of IVb in $d_2$-dichloromethane are presented in Figure 7.

Figure 7

At 88°C two sets of three free alkenyl proton resonances were observed

at 4.41, 4.60($H_3$ and $H_3'$), 5.15 and 5.31 $\tau$($H_1$,$H_2$,$H_1'$ and $H_2'$, overlapping), in addition to three coordinated alkenyl proton resonances at 6.00, 6.39 and 6.68. At 7°C two overlapping sets of three alkenyl proton resonances were present, while at 22°C only three alkenyl proton resonances were observed. It appears, then, from the $^{31}P\{^1H\}$, $^{13}C\{^1H\}$ and $^1H$ FTNMR spectral data, that there are, in fact, <u>two</u> low temperature exchange processes occurring for IVb in solution. The first involves exchange of one butenyl side-chain on each phosphine ligand between free and metal-coordinated sites, yielding equivalent phosphine ligands, one set of alkenyl carbon resonances due to the two non-fluxional butenyl side-chains and two sets of alkenyl proton resonances due to the two non-fluxional butenyl side-chains and the two exchange-averaged butenyl side-chains. The second process involves exchange of all four butenyl side-chains, yielding equivalent phosphine ligands, one set of exchange-averaged alkenyl protons and no observed alkenyl carbon resonances. The activation energy ($\Delta G^{\ddagger}$) for the exchange of the first two butenyl side-chains is easily obtained from the $^{31}P\{^1H\}$ FTNMR spectra and is found to be 10.0 $\pm$ 0.5 kcal/mol.[39] The second process may be due to the onset of rotation about the ruthenium-phosphorus bond which would interchange the two butenyl side-chains on each phosphine ligand, thus enabling all four butenyl side-chains to exchange between free and coordinated sites.

The $^{11}B\{^1H\}$ FTNMR of IVb in $d_2$-dichloromethane at -71°C resembled that of IVa at -40°C and illustrated the asymmetry induced in the carborane ligand when the phosphine ligands become inequivalent.

Complexes IVa-b reacted with carbon monoxide to form the yellow complexes [<u>closo</u>-6-CO-6,6-$L_2$-6,2,3-$RuC_2B_7H_9$](IVa-b; L=MBP or DBP). The infrared spectra of IVa-b included $\nu_{CO}$ absorptions at 1932 and 1930 $cm^{-1}$ and $\nu_{C=C}$(uncoordinated) at 1628 and 1632 $cm^{-1}$, respectively. The $^1H$ NMR spectra in $d_2$-dichloromethane contained alkenyl proton resonances due to uncoordinated butenyl side-chains and exhibited no temperature-dependent behavior.[40] The presence of a mirror-plane was

indicated by the $^{11}B\{^1H\}$ and $^{31}P\{^1H\}$ NMR spectral data suggesting that the carboranyl cage mirror plane bisects the P-Rh-P angle in a static structure or, alternatively, that the $\{RhP_2CO\}$ vertex is rapidly rotating about the five-membered face of the carboranyl ligand as has been proposed for [closo-$\{P(C_2H_5)_3\}_3RuC_2B_7H_9$] at -88°C.[4]

The carbonylation of IVa produced Va in quantitative yield when monitored by $^{31}P\{^1H\}$ FTNMR at -78°C. At temperatures above 25°C, however, the carbonylation of IVa produced two additional singlet resonances at -15.3 and 45.4 ppm which were assigned to free but-3-enyldiphenylphosphine and to [closo-6,6-$(CO)_2$-6-L-6,2,3-$RuC_2B_7H_9$] (IIIb;L=MPB), respectively. The infrared spectrum of IIIb in the 2100-1900 $cm^{-1}$ region was very similar to that of the analogous complex, IIIa.

## Conclusions

Reactions of [hyper-closo-2-$R^1$-3-$R^2$-6,6-$(PPh_3)_2$-6,2,3-$RuC_2B_7H_7$](I) with SP($R^{1,2}$=H,$CH_3$; $R^1$=H; $R^2$=Ph); AP($R^{1,2}$=H,$CH_3$), MBP and DBP($R^{1,2}$=$CH_3$) yielded the unsaturated ruthenacarborane complexes [hyper-closo-RuL($C_2B_7H_7R^1R^2$)](IIa-g), in which the alkenyl phosphine (L) functions as a bidentate ligand. The molecular structure of IId(L=AP, $R^{1,2}$=$CH_3$) was determined by X-ray diffraction to be similar to that of $[(\eta^5\text{-}C_5H_5Fe)_2C_2B_6H_8]$[10] and represents a new structural class of ten-vertex metallocarboranes containing ten skeletal electron pairs. The term "hyper-closo" has been adopted to describe this structural class of which $[(\eta^5\text{-}C_5H_5)_3Co_3B_4H_4]$,[31] $[(\eta^5\text{-}C_5H_5)CoFe(CH_3)_4C_4B_8H_8]$[41] and $[EFe(CH_3)_4\text{-}C_4B_8H_8]$[41] (E=Sn,Ge) are also members, in order to differentiate these species from undistorted, unsaturated metallocarboranes, in which the electronic unsaturation is presumably largely metal-based. Studies are now underway in this laboratory to isolate and determine the molecular structure of twelve and eleven-vertex hyper-closo metallocarboranes in order to elucidate the nature

of the polyhedral distortions induced by the unsaturated metal vertices.

Reactions of [hyper-closo-6,6-$(PPh_3)_2$-6,2,3-$RuC_2B_7H_9$] with MBP and DBP yielded the saturated ruthenacarborane complexes [closo-$RuL_2(C_2B_7H_9)$](IVa,b). A variable temperature multinuclear FTNMR study of IVa,b indicated that the complexes undergo butenyl side-chain exchange in solution at lower temperatures and undergo closo-hyper-closo equilibria with concomitant polyhedral rearrangement at higher temperatures. This facile rearrangement demonstrates the remarkable mobility of transition metal vertices in cluster complexes and the flexibility of carborane cages in accommodating both electronic and coordinative unsaturation in the transition metal vertex.

Several interesting metallocarboranes containing carboranyl cage-bonded alkenyl side-chains have recently been prepared in this laboratory and the chemistry of these catalytically active species is currently under investigation.[42]

## EXPERIMENTAL SECTION

### Crystal Structure

Crystals of IId suitable for X-ray studies were obtained as black needles from $CH_2Cl_2$/pentane. A preliminary examination of several crystals by means of oscillation and Weissenberg photographs showed them to have monoclinic symmetry and systematic absences 0k0, k = 2n + 1, and h0ℓ, ℓ = 2n + 1, space group $P2_1/c$.[43] The specimen selected for data collection was bounded by $\{\bar{1}02\}$, {010}, {110} and $\{1\bar{1}0\}$. Crystal dimensions normal to these faces were 0.20, 0.16, 0.19, and 0.075 mm, respectively. The crystal was mounted on a Syntex $P\bar{1}$ autodiffractometer equipped with a scintillation counter and a graphite monochromator. Lattice parameters, determined by a least-squares fit of 15 accurately centered high-angle reflections, were a = 11.740(3) Å, b = 15.185(5) Å, c = 21.748(7) Å, and $\beta = 137.43(2)^{\circ}$. The density measured by flotation in aqueous potassium iodide

was 1.36(1) g $cm^{-3}$, in good agreement with the calculated density of 1.368 g $cm^{-3}$ based on Z = 4.

Intensity measurements were made with MoKα radiation scan rate of 2.0°/min from 1.25° below the $K\alpha_1$ reflection to 1.25° above the $K\alpha_2$ reflection. The background was counted for one half of the scan time at each end of the scan range. Data were collected with a θ-2θ scan technique to a limit of 2θ = 55°. Three strong reflections were checked after each 97 intensity measurements and these showed only random variations consistent with their respective σ(I) values. Of the 6052 unique reflections not excluded by the space group, 1884 for which $I < 3\sigma(I)$ were considered unobserved. The remaining 4168 reflections were used in the structure determination and refinement. All measured reflections were corrected for Lorentz and polarization effects and processed to give $|Fo|$ values as previously reported.[44] An absorption correction was applied (μ = 6.60; maxium and minimum transmission factors were .9559 for $\overline{13}$ 0 18 and .9479 for $\overline{11}$ 0 28.

Determination and Refinement of the Structure

Trial positions for the ruthenium and phosphorus atoms were obtained from a three-dimensional Patterson summation. The other atoms, including hydrogen atoms, were located by means of difference Fourier maps. Refinement, without the contribution of hydrogen atoms to calculated structure factors, of positional and anisotropic thermal parameters of the ruthenium and phosphorus atoms and of positional and isotropic thermal parameters of all other nonhydrogen atoms, converged to a conventional R[45] index of 5.5% and a weighted index, $R_w$, of 7.5%. For reasons of economy, the two $C_6H_5$ moieties were then constrained to be rigid groups[46] containing $C_6$ hexagons of C-C = 1.39 Å and C-H = 1.0 Å. Maxima in the range of 0.5 ± 0.2 e $Å^{-3}$ at positions close to those calculated for the remaining hydrogen atoms were found on a difference Fourier map. The two methyl groups were also constrained to be rigid groups containing an $sp^3$ carbon atom and C-H =

1.0 Å. Positional and anisotropic thermal parameters of all nonhydrogen nongroup atoms, positional and isotropic thermal parameters of all carbon group atoms and positional parameters of all nongroup hydrogen atoms were refined. Isotropic thermal parameters for all hydrogen atoms were assigned as follows: for all nongroup hydrogen atoms B = 5.0, for all phenyl group hydrogen atoms B = 0.5 plus the B value on the adjacent carbon atom, and for all methyl group hydrogen atoms B = 1.0 plus the B value on the adjacent carbon atom. The refinement converged at R = 4.0% and $R_w$ = 4.8%. In the final least-squares cycle, the largest shift in a positional or thermal parameter for a nonhydrogen atom was 0.4σ. The final "goodness of fit" defined as $[\Sigma w(|Fo|-|Fc|)^2/(No-Nv)]^{1/2}$ was 1.47. In this expression No = 4168, the number of observed reflections, and Nv = 267, the number of variable parameters. No maxima > 0.75 e Å$^{-3}$ were found on a final difference Fourier map.

The final positional and thermal parameters are listed in Tables I, II, and III. A listing of the root-mean-square amplitudes of vibration of the nonhydrogen nongroup atoms along the three principal axes of the vibrational ellipsoids, together with the corresponding B values, is given in Table IV.[47] A set of structure factors was calculated on the basis of the tabulated parameters and is available as Table V.[47] The atomic scattering factors were those given in Table 2.2A of ref. 48 and the real and imaginary components of anomalous dispersion from Table 2.3.1 of ref.43 were applied to the scattering factors of ruthenium and phosphorus.

Synthesis of Metallocarboranes

Unless indicated otherwise, all operations were conducted under purified nitrogen or argon using standard inert atmosphere techniques.[49]

Infrared spectra were determined as mineral oil mulls or KBr pellets on a Perkin-Elmer 421 dual-grating spectrometer. Proton NMR spectra were measured using Varian A60D and HA100D spectrometers. $^{13}C$ NMR spectra were recorded on

a Varian CFT-20 spectrometer. The 80.5 and 111.8 MHz $^{11}B$ FTNMR spectra were obtained with an instrument designed and constructed by Professor F. A. L. Anet of this department. All other FTNMR spectra were recorded on a Brüker WP-200 spectrometer equipped with a B-ST-100/700C variable temperature unit. $^{11}B$ and $^{31}P$ chemical shifts were referenced to external $BF{\cdot}OEt_2$ and $D_3PO_4$, respectively, with positive valves assigned to low-field shifts and all reported coupling constants are absolute values. All NMR solvents were vacuum distilled from $P_4O_{10}$ into the NMR sample tube prior to sealing under vacuum ($< 5 \times 10^{-5}$ torr). Mass spectra were obtained on an Associated Electrical Industries MS-9 spectrometer.

Melting points were determined in open capillaries and are uncorrected. Elemental analyses were performed by Schwarzkopf Microanalytical Laboratories, Woodside, N.Y.

The complex [hyper-closo-2-$R^1$-3-$R^2$-6,6-$(PPh_3)_2$-6,2,3-$RuC_2B_7H_7$] was prepared by a previously described procedure.[4] SP[6], AP[7], MBP[8] and DBP[8] were prepared by literature methods. Toluene, benzene and petroleum ether (30-60°C) were distilled from calcium hydride. Other solvents were reagent grade and deoxygenated with bubbling nitrogen or argon immediately before use. All other chemicals were reagent grade and used as supplied.

Preparation of [hyper-closo-6-(SP)-6,2,3-$RuC_2B_7H_9$](IIa)

A toluene (2 ml) solution of $[Ru(PPh_3)_2(C_2B_7H_9)]$ (0.101 g, 0.138 mmol) and SP (0.0875 g, 0.304 mmol) was stirred overnight at room temperature yielding a deep blood-red solution. Pentane (10 ml) was gently layered above the toluene solution and the mixture was cooled to -15°C for 3 d. The resulting red-brown crystals of $[Ru(SP)(C_2B_7H_9)]$(IIa) (0.049 g, 68%) were filtered off in air, washed with methanol and pentane and vacuum dried, m.p.: 193-197°C. Anal. At -71°C: 24.9(2), -3.4(2) and -19.9 ppm(3). Infrared spectrum (KBr): $\nu_{C=C}$ (uncoordinated) at 1633 $cm^{-1}$.

Preparation of [closo-6-CO-6,6-$(DBP)_2$-6,2,3-$RuC_2B_7H_9$](Vb)

Dry carbon monoxide was bubbled through a solution of [$Ru(DBP)_2C_2B_7H_9$] (IIIb) (0.150 g, 0.232 mmol) in toluene (5 ml) yielding a bright yellow solution. Upon addition of petroleum ether (10 ml) and cooling to -15°C for 1 d, yellow crystals of [closo-6-CO-6,6-$(DBP)_2$-6,2,3-$RuC_2B_7H_9$](Vb) (0.133 g, 87%) were obtained, m.p.: 121-123°C. Anal. Calcd for $C_{31}H_{47}B_7P_2ORu$: C, 55.21; H, 7.02; P, 9.18. Found: C, 54.78; H, 7.14; P, 9.66. $^1H$ FTNMR (200.133 MHz, $C_6D_6$):

2.40 (m,2H), 2.60 and 2.98 (m,4H)(phenyl protons), 4.52(m,4H,$H_3$), 5.11 (d, $J_{13}$=11 Hz, 4H,$H_1$), 5.17 (d, $J_{23}$=24 Hz, 4H,$H_2$), 6.59 (br,s,2H, carborane C-H), 8.11 and 8.60 τ(m,8H, methylene protons). $^{31}P\{^1H\}$ FTNMR (81.02 MHz, 20% $CD_2Cl_2$-$CH_2Cl_2$): 29.7 ppm(s). $^{11}B\{^1H\}$ FTNMR (80.5 MHz, $CD_2Cl_2$): 0.00(2), -9.13(1) and -23.4 ppm(4). Infrared spectrum (KBr): $\nu_{CO}$ at 1930(s,br), and $\nu_{C=C}$ (uncoordinated) at 1632 $cm^{-1}$(s).

The complex [closo-6-CO-6,6-$(MBP)_2$-6,2,3-$RuC_2B_7H_9$)(Va)(70 mg, 77%) was similarly prepared from [$Ru(MBP)_2(C_2B_7H_9)$](93 mg, 0.13 mmol) at -78°C. m.p.: 174-176°C (melts to a red liquid, darkens at 165°C). Anal. Calcd for $C_{35}H_{43}$-$B_7P_2ORu$: C, 58.52; H, 6.03; P, 8.62. Found: C, 58.18; H, 6.15; P, 8.33. $^1H$ FTNMR (200.133 MHz, $C_6D_6$): 2.42 (m,4H), 2.89 and 3.08 (m,8H)(phenyl protons), 4.63 (m,2H,$H_3$), 5.18 (d, $J_{13}$=10 Hz, 2H, $H_1$), 5.25 (d, $J_{23}$=17 Hz, 2H, $H_2$), 6.70 (br,s,2H, carborane C-H), 7.79 and 8.04 τ(m,4H, methylene protons). $^{31}P\{^1H\}$ FTNMR (81.02 MHz, 20% $C_6D_6/C_6H_6$): 42.5(s). $^{11}B\{^1H\}$ FTNMR (80 MHz, $CD_2Cl_2$): 0.4(2), -8.2(1) and -22.0 ppm(4). Infrared spectrum (KBr): $\nu_{CO}$ at 1932 (s,br) and $\nu_{C=C}$ (uncoordinated) at 1628 $cm^{-1}$(w). The carbonylation of IVa was monitored by $^{31}P\{^1H\}$ FTNMR at several temperatures using rubber septa and a syringe needle. ([IVa] ≃ 0.03M). At -78°C in 10% $C_6D_6$-$C_6H_5CD_3$: 45.0 ppm(s). At 30°C in 10% $C_6D_6$-$C_6H_6$: 45.4 (s,1), 42.5 (s,5) and -15.3 ppm (s,1) (≈30% IIIb). At 60°C in 10% $C_6D_6$-$C_6H_5CD_3$: (The sample was carbonylated at 60°C and the spectrum recorded at 30°C) 45.5 (s,1), 42.5 (s,2) and -15.3 ppm (s,1) (≈50% IIIb). Infrared spectrum of IIIb (Nujol): $\nu_{CO}$ at 1970 and 2025 $cm^{-1}$.

[a]Atomic positional parameters for atoms which have been treated as members of rigid groups are listed in Table II.

[b]The numbers given in parentheses here and in succeeding tables are the estimated standard deviations in the least significant digits.

[c]Hydrogen atoms are numbered according to the number of the atom to which they are bonded.

Table III (cont'd)

[a]All values of β have been multiplied by $10^5$. The anisotropic temperature factor expression is of the form: $\exp[-(\beta_{11}h^2 + \beta_{22}k^2 + \beta_{33}\ell^2 + 2\beta_{12}hk + 2\beta_{13}h\ell + 2\beta_{23}k\ell)]$. The hydrogen atoms were assigned fixed isotropic thermal parameters: all cage hydrogen atoms had B values fixed at 5.0 $\text{Å}^2$, all other hydrogen atoms which are not members of rigid groups also were assigned B=5.0 $\text{Å}^2$, all methyl group hydrogen atoms were assigned B values 1.0 $\text{Å}^2$ greater than the B value on the adjacent carbon atom, and all phenyl group hydrogen atoms were assigned B values 0.5 $\text{Å}^2$ greater than those of the adjacent carbon atoms.

## ABSTRACT

Reactions of [hyper-closo-2-$R^1$-3-$R^2$-6,6-$(PPh_3)_2$-6,2,3-$RuC_2B_7H_7$](I) with (o-styryl)diphenylphosphine ($R^{1,2}$=H,$CH_3$; $R^1$=H,$R^2$=Ph), (o-allylphenyl)diphenylphosphine($R^{1,2}$=H,$CH_3$) and $Ph_{3-n}P(CH_2CH_2CH{=}CH_2)_n$(n=1,2; $R^{1,2}$=$CH_3$) afforded the 16e$^-$ ruthenacarborane complexes [hyper-closo-RuL($C_2B_7H_7R^1R^2$)] (IIa-g), in which the alkenyl phosphine (L) functions as a bidentate ligand. The crystal structure of [2,3-$(CH_3)_2$-6-($CH_2$=$CHCH_2C_6H_4Ph_2P$)-6,2,3-$RuC_2B_7H_7$](IId) was determined from three-dimensional X-ray counter data. The complex crystallizes in the monoclinic system, space group $P2_1/c$ with a=11.740(3) Å, b=15.185(5) Å, c=21.748(7) Å, $\beta$=137.43(2)$^o$ and Z=4. Refinement of 4168 independent reflections with I>3$\sigma$(I) led to a final value of R=4.0%. The structure of this complex may best be described in terms of a $C_2B_7$ fragment of arachno-geometry which occupies nine vertices of an eleven-vertex octadecahedron with a ruthenium atom in a "non-vertex" position and within bonding distance of six atoms in the open face. The observed distortion from the common ten-vertex bicapped square antiprismatic structure is thought to be a result of the perturbation of the polyhedral skeletal bonding induced by the sixteen-electron $Ru^{II}$ center. Reaction of (IIb) with carbon monoxide displaced the coordinated alkenyl side-chain to yield the 18e$^-$ $Ru^{II}$ complex [closo-6,6-$(CO)_2$-6-L-6,2,3-$RuC_2B_7H_9$](IIIa){L=(o-allyphenyl)-diphenylphosphine}.

Reactions of $Ph_{3-n}P(CH_2CH_2CH{=}CH_2)_n$(n=1,2) with [hyper-closo-6,6-$(PPh_3)_2$-6,2,3-$RuC_2B_7H_9$] produced the fluxional complexes [closo-6,6-$L_2$-6,2,3-$RuC_2B_7H_9$] (IVa-b) which exhibit butenyl side-chain exchange and undergo closo-hyper-closo equilibria as evidenced by variable temperature multinuclear FTNMR spectroscopy. The reactions of (IVa-b) with carbon monoxide are also discussed.
