1.0 INTRODUCTION

This progress report covers the period 1 March to 28 September, under contract no. DAAK10-79-C-0040. This program is for the Design and Development of the XM746 Practice Fuze Spotting Charge.

1.1 Background

In March the requirements for a settable ogive were dropped, which allowed the use of the standard PDM 739 Fuze, modified to the XM747 Fuze. Also, the visible range for the spotting charge was increased 2000m - from 2000m to 4000m.

Tests of 3 candidate spotting charges were conducted at Yuma Proving Grounds (YPG) in April and at Ft. Sill in June to select the most suitable charge for the XM747 Fuze; however, due to dust clouds created on impact at YPG, the signature tended to be obscured. At Ft. Sill, 2.6 inches of rain fell on the impact area the day before, resulting in an extremely soft and muddy impact area. The smoke signal from the fuze impact was smothered by the impact medium and the signal was either minimal or not visible. Due to the above, a full determination could not be made but the results indicated additional development was necessary.

1.2 Design Modifications

As a result of the YPG and Ft. Sill tests, two design modifications to improve the spotting charge display were decided to be worth development and evaluation:

- Drilling of four 1/2 inch holes toward the rear of the projectile to allow smoke exit ports to be exposed to the atmosphere for a longer period of time (about 2-milliseconds) before being buried in the impact medium.

- Modify the granulation and ignition systems of the candidate pyrotechnic compositions to reduce functioning times.

1.3 Static Testing at MBA

Static testing of a matrix of the modified designs was conducted over an 8 day period starting on 9 September.

1.3.1 Object of Test

7:1141 → The primary object of the test was to determine function time, smoke cloud size and duration of Ordnance Research Inc. (ORI) type B & type C charges, ARRADCOM MOD E and MOD E1 charges and the MBA improved ~~TiCl₄~~ ARRADCOM MOD E charge. See Table 1 for compositions. Based on the test results, the best performing ORI and ARRADCOM configuration was to be carried forward for ballistic range testing at Ft. Lewis. In the case of the MBA design, it would be carried forward only if the function time was fast enough to indicate a reasonable probability of success. As discussed below, the function time was adequate to justify continued development.

1.3.2 Hardware

The hardware used in the testing was the M107 (155mm) Projectile and XM747 Fuze. The GFE fuzes were received with six .437 dia. holes. The holes were taped 1/2-20 and screws were used as necessary, see Figure 1, to meet the test plan for 0, 3 & 6 holes in the fuze. The projectile had four .500 holes drilled radial into the body 7.500 in. from the base, see Figure 2.

MBA blended the ARRADCOM composition MOD E and E1 and loaded the composition into GFE plastic containers, see Figure 3, to ARRADCOM specifications. See Table 2 and attachments A & B for blending and loading records.

Two TiCl₄ container designs were considered and identified as configuration A & B. The A configuration was rejected due to the fact it projected beyond the rear of the fuze, see Figure 4, which would cause packaging problems in the event of a future production program. The B configuration is contained within the fuze body, see Figure 5. To accomplish this, it was necessary to reduce the TiCl₄ charge from 22cc to 18cc and reduce the expulsion charge from 47 to 27 grams relative to the A configuration. The charge container length was also reduced by 3/4 in.

ORI supplied their spotting charge ORI "B" and "C" in sealed containers for the test.

Copper (Cu)	5 max.		

SAFETY AND HANDLING

Titanium tetrachloride must be maintained under inert atmosphere. Nitrogen containing less than 10 ppm oxygen is recommended. Exposure to moisture in the air generates hydrochloric acid and titanium dioxide. Refer to the titanium tetrachloride "Product Safety Information" sheet for safety information, and to the Stauffer brochure "A Guide to Cylinder Unloading."

1.3.3 Testing

A total of 54 tests of the various spotting charges and smoke port configurations were conducted, see Table 3 for Test Plan. The fuzes were assembled to the M107 projectile, placed in a test fixture and fired with an electric squib, see Figure 6.

ARRADCOM and Ft. Sill representatives witnessed the test series and evaluated the spotting charges and hardware configurations.

1.3.4 Instrumentation and Equipment

- a. Molelectron Model PR-100 electric radioment, amplifier and a CIC Model 5-124 recording oscillograph for energy output of the spotting charge.
- b. Hy Cam Hi Speed 16mm camera to record function times.
- c. Scoopic 16mm camera for film coverage of the testing.
- d. Velocity screens to a digital counter for instantaneous function time read out, see Figure 7 for typical hook-up.
- e. Agastat step timer to control function times between cameras and fuze detonation. See Figure 8.
- f. Walk-in oven for temperature conditioning of fuzes to -30°F and $+130^{\circ}\text{F}$ for 12 hours, see Figure 9.

1.3.5 Test Summary

The first 11 tests were devoted primarily to selecting the best ARRADCOM and ORI spotting charge configuration.

The fuzes were assembled as shown in Figure 1 except the 6 holes were not plugged. Based on previous designs, 2-.050 steel spacers were placed between the booster cup and the spotting charge to prevent rupturing the booster cup base. This was done to insure expelling the total charge out of the fuze ports.

NOTE: ORI "C" & MOD "E" ALL DISPLAYED GOOD SMOKE AND FLASH.
TICL4/MOD "E" EXCELLENT SMOKE FOR LONGER DURATION. GOOD FLASH.

Based on visual observations, review of the 16mm film and examination of function time data, see Table 4, ARRADCOM's MOD E was selected over the MOD E1. It was apparent the mild detonating fuze (MDF) did not improve function time. ORI "C" was selected primarily on the basis of more smoke than ORI "B" composition.

A series of tests were conducted to verify the distribution of the spotting charge output between the fuze and projectile ports (see Tables 3 and 4). It was also necessary during this test series to determine the need, if any, for a .050 steel spacer to slightly delay the rupturing of the booster cup and distribute the spotting charge between the fuze and projectile ports. During tests 12, 13, 15 & 17, see Table 4, the booster cup did not rupture as planned. Based on these results, it was concluded that the .050 spacer be removed for all future tests.

Tests no. 18 thru 24 with the 6 fuze ports blocked off, 5 of the cups ruptured, see Figure 9, and 2 of the fuze bodies (tests 22 and 24) had tensile failure in the area of smoke port, see Figure 10. The failure was attributed to the modification of the fuze (the addition of 6 smoke ports) which removed about 70% of the material in the area of the failure.

As a result of the above test failures it was decided that the balance of testing be conducted with unmodified PDM739 fuzes (without six .437 dia. holes).

The balance of the testing went relatively problem free with only minor instrument problems.

In comparing ORI "C" and MOD "E" cloud size and duration, no major difference could be seen; however, the flash seemed to be more intense coming from the ORI "C" charge. The MBA $TiCl_4$ /MOD "E" cloud, when compared to OR "C" and MOD "E", was much more intense and its duration considerably longer, in the order of 15-20 sec. compared to about 5-10 sec. The film clips in Figure 11, A, B & C, show the typical spotting charge of the MOD "E", ORI "C" and MBA $TiCl_4$ exiting from the rear of the projectile shortly after fuze function (MOD "E" at 10.0 MS, ORI "C" 14.0 MS and MBA $TiCl_4$ 11.0 MS).

Figure 12 presents ARRADCOM's estimate of the worst case, most rapid burial condition for the 155mm projectile in question. This condition exists in deeply saturated light sand soils. The ARRADCOM model predicts coverage of the smoke ports located 19 inches back on the projectile, 1.8 milliseconds after impact.

MBA has performed a similar, though less detailed, analysis using data from Lawrence Livermore Labs. which predicts a worst case burial time on the order of 2.2 milliseconds. One sigma error band on the MBA model is on the order of 0.5 milliseconds.

$$1.7 \text{ ms} \ll \text{Burial Time} \ll 2.7 \text{ ms}$$

There is probably a similar, though unknown to MBA, error band on the ARRADCOM model and in any event, the predictions from both models agree reasonably well. They both indicate that for worst case impact conditions, a design that produces significant quantities of smoke in approximately 1.7 to 1.8 milliseconds should be very effective when functioned on soft impact medias.

Unfortunately, this is not the case. The fastest mix, ARRADCOM MOD E, per Table 4, begins visible generation in approximately 2.0 ms and the MBA TiCl_4 configuration using the ARRADCOM MOD E mix as an expulsion charge plus flash and smoke enhancer has an equivalent time of approximately 2.5 ms. The ORC "C" configuration is very slow relative to the other two candidates with a smoke on-set time in the 6.0 millisecond range.

If the mathematical models are approximately correct, the ORC configuration will prove to be unacceptably slow. Hope can be held out for the other two configurations because their function times are within the error band. The ARRADCOM version has a function time very close to the ARRADCOM model mean time and faster than the equivalent MBA model time.

Expulsion port geometry can further improve the probability of achieving a visible cloud on soft media impact. The ports can be canted back at 45 degrees. With the choked flow gases exiting at Mach 1 from the canted ports, the gases will have a net forward velocity component approximately 1/3 that of the shell at the critical period when they flow into the circular cavity between the shell and ejected from impact.

FIGURE 12

L. POST
NOV. 79

The temperature testing (-30°F and $+130^{\circ}\text{F}$) showed no real change in function time or cloud size compared to ambient temperature testing.

The TiCl_4 B configuration containers were used in Tests 52, 53 and 54 with no noticeable change in cloud size and function time.

Only a small number of tests were covered with the radiometer due to instrumentation problems.

The radiometer data sheet summary shows the peak intensity in each wavelength region, see Table 5. From the ratio of these intensities, an estimate of the maximum temperature (related to grey body temperature and atmospheric conditions) can be made.

The duration of time that the fuze was observed to burn, and the delay between initiating the fire control signal and the rise of fuze intensity was also recorded.

The measurement probes of the radiometers are spectrally filtered to separately measure intensity in the 1.7 - 2.8 micrometer range and the 3-5 micrometer range. Calibration was referenced to a Barnes Model 11-200T, 1060°C black body source for each set of measurements. See Figure 13.

Because of the low total power produced, the radiometers were moved as close as practical to the test fuze. The 7-1/2 degree field of view permitted measurements at 40 feet.

In its simplest form the radiometer equation is (1)

$$I = \text{CVR}^2$$

where

I = source intensity in w sr^{-1}

C = radiometer calibration in
 $\text{w sr}^{-1} \text{ v}^{-1} \text{ ft}^2$

V = radiometer output voltage

R = source to radiometer distance in feet

The I/R^2 dependence of voltage on intensity is a result of the fact that the radiometer has no imaging optics and thus simply measures irradiance (watts per square meter at the detector).

TABLE 5

FIGURE 13
RADIOMETER BLACK SOURCE AND CONTROL

The radiometer response is a function of the wavelength of the incident radiation. This is because the atmosphere between the source and the radiometer; as well as the window, filter and detector, have wavelength dependent responses.

The equation which describes the radiometer voltage output for an irradiance of the radiometer by a monochromatic source of wavelength λ is

$$V(\lambda) = E \cdot sV_d(\lambda) \cdot T_a(\lambda) \cdot T_w(\lambda) \cdot T_f(\lambda)$$

where

E = the irradiance in w m^{-2} in the plane of the detector in the absence of the radiometer or an atmosphere.

$sV_d(\lambda)$ = the spectral detector response in $\text{vm}^2 \text{w}^{-1}$ for a given level of irradiance at wavelength λ . The term $V_d(\lambda)$ is a relative response of the system while s is a parameter that reflects the radiometer sensitivity. It may change with time or environment and thus makes periodic calibration necessary.

$T_a(\lambda)$, $T_w(\lambda)$, and $T_f(\lambda)$ = respectively the spectral transmittance of the atmosphere between the source and the radiometer, the radiometer window, and the radiometer filter.

Analysis for Ballistic Testing

The stress analysis on the critical components, i.e., the booster cup base and the cup/body interface, shows adequate margins of safety for safe operation (see Appendix A). In lieu of actual data on internal pressure required to separate or fail the cup base during detonation, an expected bursting pressure was calculated.

Factor of safety used in the margin of safety calculations were 1.15 applied to the yield allowable and 1.5 applied to the ultimate allowable. These values are standard aerospace practice. Because of the extremely high acceleration forces or set-back loads, the actual margins of safety during normal handling operations are far in excess of hazardous material requirements.

The methods, referenced in the analysis, are standard practice and should not cause concern over their validity. As demonstrated in the analysis, the minimum margin of safety occurred at the cup base material thickness transition from 0.040 inches to 0.104 inches. This margin is 0.80 on yield which represents a stress level 80 percent below the material allowable when reduced by the yield factor of safety. The most critical area is therefore approximately twice as strong as required to support the worse case loading.

The analysis also predicts a bursting pressure of 10,500 psi which appears to be compatible with good performance during the detonation event. Although actual pressures are not known, they are anticipated to be in the order of 20,000 psi if totally contained. This two to one pressure ratio is comfortable for good reliable failure expectation.

1.4 Plans for Next Period

Fabricate, assemble and deliver hardware to Ft. Lewis for test on or about November 6th, 42 each MOD E charges; 26 each ORIC charges; 8 each 747 Fuzes with MOD E and ORIC charges; 26 each 747 Fuzes without charges; 34 each 747 Fuzes with MBA charges; and 16 each 747 Fuzes with 6 each .437 dia. holes.

1.5 Expenditures

Expenditures for January through September, \$77,500.

$$\therefore f_t = .3 \cdot f_r = 6600 \text{ PSI}$$

DETERMINE MAXIMUM OCTAHEDRAL STRESS

SEE "ANALYSIS AND DESIGN OF FLIGHT VEHICLE STRUCTURES," EF BRUNN, 1965, CHAPTER C1 p. C.17 FOR OCTAHEDRAL SHEAR STRESS THEORY.

$$f_{max} = \sqrt{f_r^2 + f_t^2 - f_r f_t}$$

$$f_{max} = \sqrt{(22)^2 + (6.6)^2 - (22)(6.6)} 10^3$$

$$= 19,500 \text{ PSI}$$

MARGINS OF SAFETY

$$MS = \frac{F_t}{F_S \cdot f_t} - 1$$

YIELD

$$MS = \frac{44 \times 10^3}{1.15(19.5 \times 10^3)} - 1 = \underline{\underline{0.96}}$$

ULTIMATE

$$MS = \frac{67 \times 10^3}{1.5(19.5 \times 10^3)} - 1 = \underline{\underline{1.29}}$$

SOLVE FOR STRESS AT $R=0.5$ (EDGE OF 0.040 THK DISC)

THE QWP BASE IS A REDUNDANT STRUCTURE & THE LOAD WILL DISTRIBUTE ON TO THE TWO BASE THICKNESS SUCH THAT THEIR INTERFACE WILL HAVE THE SAME DEFLECTION. THE DISTRIBUTION WILL BE INVERSELY PROPORTIONAL TO THEIR DEFLECTION. ASSUME THE PLATE STIFFNESS RATIO IS PROPORTIONAL TO t^3 AS FOR A BEAM IN BENDING THEN THE LOAD ON THE CENTER WILL BE

$$W_c = \frac{(0.04)^3}{(.104)^3 + (.04)^3} W$$

$$= 66 \text{ LB} \cdot 0.54$$

AGAIN FROM ROARK CASE 8 AT $r = 0.5$

$$f_r = \frac{3W}{2\pi m t^2} \left[(m+1) \log \frac{a}{r_0} + (m+1) \frac{r_0^2}{4a^2} - (3m+1) \frac{r^2}{4r_0^2} \right]$$

$$(m+1) \log \frac{a}{r_0} = \left(1 + \frac{1}{3}\right) \log \frac{.6475}{.5} = 0.486$$

$$(m+1) \frac{r_0^2}{4a^2} = \left(1 + \frac{1}{3}\right) \left(\frac{.5}{1.295}\right)^2 = 0.646$$

$$(3m+1) \frac{r^2}{4r_0^2} = \left(1 + \frac{3}{3}\right) \left(\frac{.375}{1.0}\right)^2 = 1.547$$

$$f_r = \frac{3(66)3}{2\pi (.04)^2} [.486 + .646 - 1.547]$$

$$= -24500 \text{ PSI}$$

(- SIGN DENOTES TENSION ON TOP SURFACE)

$$f_t = -\frac{3W}{2\pi m t^2} \left[(m+1) \log \frac{a}{r_0} + (m+1) \frac{r_0^2}{4a^2} - (m+3) \frac{r^2}{4r_0^2} \right]$$

$$(m+3) \frac{r^2}{4r_0^2} = \left(\frac{1}{3} + 3 \right) \left(\frac{.375}{1.0} \right)^2 = 0.890$$

$$f_t = -\frac{3(66)3}{2\pi(.04)^2} [.486 + .646 - .890]$$

$$= -14,300 \text{ PSI}$$

MAXIMUM STRESS AT $r = 0.375$

$$f_{max} = \sqrt{(24.5)^2 + (14.3)^2 - (24.5)(14.3)} \times 10^3$$

$$= 21,300 \text{ PSI}$$

MARGINS OF SAFETY

YIELD

$$MS = \frac{44 \times 10^3}{(1.15)(21.3)10^3} - 1 = \underline{\underline{0.796}}$$

ULTIMATE

$$MS = \frac{67 \times 10^3}{(1.5)(21.3)10^3} - 1 = \underline{\underline{1.097}}$$

THE MBA CONFIGURATION IS IDENTICAL TO MOD E FOR CJP BASE LOADING & THE MOD E STRESS ANALYSIS APPLIES.

MBA CONFIGURATION - THREAD SHEAR

MATERIAL PROPERTIES

2024-T4 AL ALLOY

$$F_{tu} = 62 \times 10^3 \text{ PSI}$$

$$F_{ty} = 42 \times 10^3 \text{ PSI}$$

$$F_{su} = 37 \times 10^3 \text{ PSI}$$

THE ALUMINUM BODY WILL BE CRITICAL BECAUSE THE ALUMINUM ALLOWABLES ARE SLIGHTLY LOWER THAN THE A-109 STEEL VALUES

THE LOAD ON THE MBA CONFIGURATION IS ≈ 3 TIMES THAT ON THE MOD E FUZE $\therefore$ ONLY THE MBA CONFIGURATION WILL BE ANALYZED

$$\text{WGT(TICL4)} = 0.565 \text{ LB}$$

$$\text{WGT(CW+SMOKE)} = 0.220 \text{ LB}$$

$$F = (.565 + .220) 11,200 = 8800 \text{ LB}$$

AREA IN SHEAR

$$A = \pi D L N$$

$$= \pi (1.446) (0.0314) (17.5)$$

$$= 2.5 \text{ IN}^2$$

$$f_s = \frac{P}{A} = \frac{8800}{2.5} = 3520 \text{ PSI}$$

MS = HIGH

CHECK BODY TENSION

$$A = \pi D_m t$$

$$= \pi (1.6)(.105) = 0.528 \text{ IN}^2$$

$$f_t = \frac{P}{A} = \frac{8800}{.528} = 16,700 \text{ PSI}$$

YIELD..

$$MS = \frac{42 \times 10^3}{1.15(16.7)10^3} - 1 = \underline{\underline{1.18}}$$

ULTIMATE

$$MS = \frac{62 \times 10^3}{1.5(16.7)10^3} - 1 = \underline{\underline{1.47}}$$

EVALUATION OF RUPTURE PRESSURE

THE PRESSURE REQUIRED TO RUPTURE THE CWP BASE CAN BE ESTIMATED BY DETERMINING THE FORCE REQUIRED TO FAIL THE BASE & THE TRANSLATING THIS FORCE INTO A PRESSURE

THE MINIMUM MARGINS OF SAFETY OCCUR AT THE CHANGE IN BASE THICKNESS, WHERE

$$f_r = \frac{3W}{2\pi m t^2} \left[(m+1) \log \frac{a}{r_0} + (m+1) \frac{r_0^2}{4a^2} - (3m+1) \frac{r^2}{4r_0^2} \right]$$

$$f_t = \frac{3W}{2\pi m t^2} \left[(m+1) \log \frac{a}{r_0} + (m+1) \frac{r_0^2}{4a^2} - (m+3) \frac{r^2}{4r_0^2} \right]$$

BECAUSE ONLY W IS A VARIABLE THE RATIO f_r/f_t WILL BE A CONSTANT EQUATION f_{max} TO THE ULTIMATE ALLOWABLE

$$F_u = f_{max} = \sqrt{f_r^2 + f_t^2} - f_r f_t$$

$$f_r/f_t = \frac{24.5}{14.3} = 1.713$$

$$F_u = \sqrt{(1.713)^2 + 1} - 1.713 \quad f_t$$

$$= 1.5 f_t$$

$$f_t = \frac{67 \times 10^3}{1.5} = 44,700 \text{ PSI}$$

$$44,700 = \frac{3W3}{2\pi(.04)^2} [.486 + .646 - .890]$$

$$W = 206.3 \text{ LB}$$

AREA OF PRESSURE ACTION

$$A = \frac{\pi}{4} (.375)^2 = 0.1104 \text{ IN}^2$$

$$\begin{aligned} \text{PRESSURE} &= 206.3 / .11 \\ &= 1870 \text{ PSI} \end{aligned}$$

THIS PRESSURE APPEARS TO BE ON THE LOW SIDE. A BETTER APPROACH MAY BE TO USE ROARK CASE 6, EDGES FIXED, UNIFORM LOAD OVER ENTIRE SURFACE.

$$f_r = \frac{3W}{4\pi t^2} \quad f_t = \frac{3W}{4\pi m t^2}$$

$$\frac{f_t}{f_r} = .3$$

$$f_m = \sqrt{(.3)^2 + 1} \cdot .3 f_t = 0.90 f_t$$

$$f_t = \frac{67 \times 10^3}{0.9} = 75400 \text{ PSI}$$

$$75400 = \frac{3W}{4\pi (.105)^2} = 65.W$$

$$W = 1160$$

$$\text{PRESSURE} = \frac{1160}{.1104} = 10,507 \text{ PSI}$$

WHICH APPEARS TO BE A MORE MEANINGFUL VALUE.
