ABSTRACT

The procedure for solving large-scale, nonlinear multiobjective optimization problems requires the use of a computer coded algorithm which is both computationally efficient and mathematically valid. The multicriteria methodology, Goal Programming, has proven to be an effective technique for the solution of such problems.

The problem of this study was the synthesis of the goal programming methodology into an efficient computer algorithm which could be used by the problem solver to solve a general class of nonlinear, multiobjective (NLGP) engineering design problems. Three such codes were developed into a computer package. Each code is capable of solving an NLGP problem. Each code has modifications which make it more attractive than the others for application to particular types of NLGP problems. The results show that these codes are effective tools for solving nonlinear goal programming design problems.

CHAPTER I

INTRODUCTION

1.1 Problem Statement

The design of the majority of large-scale, complex engineering systems requires the specification of parameters which will best achieve a system of multiple and conflicting design objectives. These objectives may be linear and nonlinear in nature. Real systems can often contain hundreds and often thousands of specific design objectives. The design parameters which optimize the performance of these objectives can number in the thousands. Unfortunately, traditional methods of modeling and optimizing such systems are restricted to problems encompassing a single design goal. Computational techniques for these methods are quite often further restricted to either small problems or uncomplicated objectives, or both.

A satisfactory technique for the solution of large-scale engineering design problems with multiple, conflicting objectives is contained within the multicriteria tool of goal programming [18]. This computational technique has been applied to a wide variety of problems. The computer code presented in [18] is intended for very small problems, while those in [2] and [14] have been adapted to meet the design requirements of very specific problems. There is a need for an improved nonlinear goal programming (NLGP) computer code which can be used without modification to solve a wide variety of general large-scale nonlinear, multiobjective design problems. The purpose of this study is to develop such a computer code.

1.2 Specific Objectives

The specific objectives of this study are:

1. To develop a computer code (or codes) which can solve NLGP problems with up to thousands of objectives and thousands of variables,

2. To test and validate the code(s) for computational efficiency,
3. To supply a User's Manual describing in detail the use of the code(s).

1.3 Summary of Results

The research work resulted in the development of three computer codes. All three are similar in technique. Each code has minor modifications from the others which makes it more suitable for application to particular NLGP problems.

The codes were tested on a variety of problems varying in the complexity of the nonlinear objectives and problem size (the number of variables and objectives). The results obtained indicate that each code is computationally correct and yielding satisfactory results.

This report contains information about the development of the computer codes with details about their structure and performance. A User's Manual has been written which details specifically how to use the three computer codes.

1.4 Overview of Following Chapters

An analysis of the results of this research are contained in the following chapters.

Chapter II contains a background sketch of the general nonlinear goal programming model. It lists advantages and limitations of the technique in solving design problems. The third chapter then provides a description of the computer codes, their limitations and modifications. Some examples are presented in Chapter IV, along with the empirical results from the testing of the codes. Finally, some conclusions about this study and recommendations for further research are provided in Chapter V.

CHAPTER II

THE MATHEMATICAL PROGRAMMING PROBLEM

2.1 The General Nonlinear Goal Programming Model

The primary emphasis of this research has been directed towards the area of multicriteria decision analysis, and in particular, nonlinear goal programming. For this reason, a discussion of the considerable number of other mathematical programming optimization techniques will not be presented. The entire focus of discussion will be on multicriteria techniques.

The multicriteria technique called Goal Programming was first presented by Charnes and Cooper [1] in the 1950's. Ignizio [18] later expanded the method to solve nonlinear as well as linear models. More recently, this technique has found a broad range of applications to solving design problems in many areas [3,13,14,15,16,17,19,20,21,22,23,24].

The general nonlinear goal programming model can be described by the following [18].

A set of mathematical equations are established by the analyst or design engineer which describe the problem as functions of the design parameters. These design equations are the objectives, some or all of which may be nonlinear in nature. The design parameters are the decision variables. Associated with the objectives are desired aspiration levels. They represent the performance of the system at the optimal design parameters.

Define the following:

- (1) $\{f_1(\bar{x}), f_2(\bar{x}), \dots, f_i(\bar{x})\}$ is the set of objectives
- (2) $\bar{x} = (x_1, x_2, \dots, x_j)$ is the vector of decision variables
- (3) $\{b_1, b_2, \dots, b_i\}$ is the set of aspiration levels for the objectives.

Then,

$$f_i(\bar{x}) \begin{matrix} > \\ = \\ < \end{matrix} b_i, \quad i = 1, 2, \dots, m$$

represent the objectives or goals for the system.

It is desired to find the values of the decision variables such that the objectives meet the specified aspiration levels. Since this is not always possible due to the conflicting nature of many objectives, deviation variables are added to the design objectives. These variables measure the difference between the desired and the actual aspiration levels.

Then,

$$f_i(\bar{x}) + n_i - p_i = b_i, \quad i = 1, 2, \dots, m$$

are the design objectives where n_i measures the negative deviation from the aspired level for objective i , and p_i measures the positive deviation for objective i .

A major assumption underlying many versions of goal programming is that the analyst can establish preemptive priorities for each objective or group of objectives. This implies that the objectives can be ordered such that achievement of the objectives at any one priority level is immeasurably preferred to the achievement of the objectives of any lower level.

Any objectives which are absolute (i.e., they must be satisfied) are assigned to priority level (P_1). The remaining objectives are then grouped and assigned priority levels (i.e., $P_2, P_3, \dots, P_j$).

The goal programming algorithm first satisfies, as nearly as possible, the objectives with the highest priority level. It then proceeds to satisfy the objectives of the next priority level, as nearly as is possible, without degrading the achievement of any objective in a higher priority level. This process continues until all priority levels have been considered.

The satisfaction of these various priority levels is measured by an achievement vector, $\bar{a}$. This vector has one component for each priority level. Each component, a_m , is a weighted linear function of the deviation variables which are contained in the objectives of that priority level m .

Let $\{g_1(\bar{n}, \bar{p}), g_2(\bar{n}, \bar{p}), \dots, g_k(\bar{n}, \bar{p})\}$ represent the set of these linear functions, one for each priority level. Each function can be represented as:

$$g_k(\bar{n}, \bar{p}) = \sum_{i \in P_k} (\mu_i n_i + w_i p_i),$$

the weighted sum of negative and positive deviation variables for all the objectives contained in priority level P_k , where μ_i and w_i are the weights.

Since both negative and positive deviation variables are required for each objective, minimization of these variables will attempt to achieve the aspiration levels of the objectives. The achievement vector $\bar{a}$ is structured as an ordered set such that the preemptive priority structure is maintained.

The standard form of the nonlinear goal programming model is as follows:

$$\begin{aligned} \text{Find } \bar{x} &= (x_1, x_2, \dots, x_j) \\ \text{to minimize } \bar{a} &= \{g_1(\bar{n}, \bar{p}), g_2(\bar{n}, \bar{p}), \dots, g_k(\bar{n}, \bar{p})\} \\ \text{subject to} \\ f_i(\bar{x}) + n_i - p_i &= b_i, \quad i = 1, 2, \dots, m \end{aligned}$$

are satisfied, $\bar{n}$ and $\bar{p}$ are both nonnegative,

- (1) $g_k(\bar{n}, \bar{p})$ is a weighted linear function of the deviation variables
- (2) k is the priority level associated with the objective
- (3) the dimension of $\bar{a}$ represents the number of preemptive priority levels, (k) ,

and

- (4) the number of preemptive priorities are equal to or less than the number of objectives.

The value of $\bar{a}$ will be equal to the zero vector if all the objectives meet their aspiration levels. The value of a_k will be a positive value if one or more objectives in priority level k are not met. The goal programming solution is considered optimal if it is the lexicographic minimum (i.e., the value of $\bar{a}$ is lexicographically the same as or less than the value of $\bar{a}$ for any other feasible solution). If a_1 is non-zero, an absolute objective cannot be met, and the solution is considered unimplementable.

To further clarify the general nonlinear goal programming model, an example problem is presented next.

2.2 A Target Allocation Example

The example problem selected to demonstrate the formulation of an NLGP model is a target allocation problem which was previously formulated and solved by Rice, Bracken, and Pennington [28] using a single objective optimization technique, the sequential unconstrained minimization technique [5,6].

This problem examines the allocation of weapon systems among targets with emphasis being placed on maximizing the amount of damage inflicted on enemy targets. The weapon systems in this problem are limited to two types of attack aircraft originating from two aircraft carriers, one conventional and one nuclear. Additionally, the number of each aircraft is considered fixed. This creates a scenario in which the primary objective of the problem is to allocate a fixed inventory of aircraft among carriers so as to maximize total damage on the enemy targets.

The following parameters and variables are introduced for this problem:

- x_{ij} = the number of aircraft of type j assigned to carrier i , $i = 1, 2$ and $j = 1, 2$
- a_{jk} = the fraction of target k (either in numbers of specific targets or target area) left undamaged following a mission by an aircraft of type j , $j = 1, 2$ and $k = 1, 2, \dots, 5$
- y_{ijk} = the number of missions flown against target k by an aircraft of type j from carrier i , $i = 1, 2$, $j = 1, 2$ and $k = 1, 2, \dots, 5$

Additional parameters are defined for the objectives with regards to the fixed supply of aircraft and carriers:

- b_j = total number of available aircraft of type j
- c_j = the carrier space required by each aircraft of type j
- d_i = total space available for plane storage on carrier i
- f_{ijk} = the fraction of total missions available in the planning period used in flying one sortie against target k by an aircraft of type j from carrier i .

The objectives for this problem are formulated as follows:

Aircraft availability constraints

$$\sum_{i=1}^2 x_{ij} \leq b_j \quad \text{for } j = 1, 2$$

Carrier space constraints

$$\sum_{j=1}^2 c_j x_{ij} \leq d_i \quad \text{for } i = 1, 2$$

Limitations on missions due to aircraft availability

$$x_{ij} - \sum_{k=1}^5 f_{ijk} y_{ijk} \geq 0 \quad \text{for } \begin{matrix} i = 1, 2 \\ j = 1, 2 \end{matrix}$$

Damage inflicted on targets

The total damage inflicted is the sum of damages to all targets.

The damage to any individual target may be expressed in terms of the parameters, a_{jk} . The damage inflicted on target k by missions of all aircraft from all carriers may be formulated as:

$$l = \prod_{i=1}^2 \prod_{j=1}^2 a_{jk}^{y_{ijk}}.$$

The total damage inflicted to all targets is the sum of damages to each target given above. Each target can be given a military target value, μ_k , which weights that target in terms of its military importance. Military importance could be an estimate of value in terms of specific numbers (i.e., number of planes destroyed), a target area or fraction of area, dollars, or some other measure.

The damage function then is:

$$\sum_{k=1}^5 u_k \left(1 - \prod_{i=1}^2 \prod_{j=1}^2 \alpha_{ijk}^{y_{ijk}} \right).$$

Also note that the variable x_{ij} and y_{ijk} are restricted to non-negative values.

The problem to be solved is: given the parameters for the problem, determine the values of the variables x_{ij} and y_{ijk} such that the total damage function is maximized subject to the aircraft, carrier, and mission constraints.

This problem will now be converted into a standard NLGP formulation. The problem variables must be converted into a standard format for the NLGP model. These model variables are listed in Table 2.1. The parameters necessary to formulate the model objectives are listed in Tables 2.2 and 2.3 and Figure 2.1. Negative and positive deviation variables have been added to the objectives.

Aircraft availability objectives

$$\text{Goal 1: } x_1 + x_3 + n_1 - p_1 = 27$$

$$\text{Goal 2: } x_2 + x_4 + n_2 - p_2 = 102$$

Carrier space objectives

$$\text{Goal 3: } 2920 x_1 + 1770 x_2 + n_3 - p_3 = 112,300$$

$$\text{Goal 4: } 2920 x_3 + 1770 x_4 + n_4 - p_4 = 147,100$$

Limitations on missions due to aircraft availability

$$\begin{aligned} \text{Goal 5: } & x_1 - 0.06452 (x_5 + x_7 + x_9) - 0.06250 (x_6 + x_8) \\ & + n_5 - p_5 = 0 \end{aligned}$$

$$\begin{aligned} \text{Goal 6: } & x_2 - 0.05556 (x_{10} + x_{12} + x_{14}) - 0.05264 (x_{11} + x_{13}) \\ & + n_6 - p_6 = 0 \end{aligned}$$

$$\begin{aligned}\text{Goal 7: } x_3 - 0.06896 x_{15} &= 0.06452 (x_{16} + x_{19}) \\ &- 0.06250 (x_{17} + x_{19}) + n_7 - p_7 = 0\end{aligned}$$

$$\begin{aligned}\text{Goal 8: } x_4 - 0.05882 x_{20} - 0.05556 (x_{21} + x_{24}) \\ &- 0.05264 (x_{22} + x_{23}) + n_8 - p_8 = 0\end{aligned}$$

Damage objective

$$\begin{aligned}\text{Goal 9: } 40 (1 - 0.99978 (x_5 + x_{15}) 0.99953 (x_{10} + x_{20})) \\ &+ 10 (1 - 0.99978 (x_6 + x_{16}) 0.99953 (x_{11} + x_{21})) \\ &+ 50 (1 - 0.99978 (x_7 + x_{17}) 0.99953 (x_{12} + x_{22})) \\ &+ n_9 - p_9 = 0\end{aligned}$$

Non-negativity objectives

$$\bar{x}, \bar{n}, \bar{p} \geq \bar{0} \text{ (the zero vector).}$$

Note that only those terms with non-zero u_k values appear in the damage objective. Scenario 1 data were used.

All that remains to be done is to formulate the achievement vector. This problem has two priority levels. Goals one through eight compose priority level one. These are absolute objectives (i.e., limited resources) which cannot be violated. Goals one through four are resource objectives. These cannot be exceeded. Therefore, the positive deviation variables for these objectives ($p_1 - p_4$) are minimized at priority level one. This prohibits overachievement of these objectives. Goals five through eight relate aircraft to missions, where the total number sent on any mission can equal to or less than the total supply but can never exceed it. Hence, the negative deviation variables ($n_5 - n_8$) are minimized. This prohibits underachievement of these objectives.

f_{ijk}	$f_{111} = 0.06452$ $f_{112} = 0.06250$ $f_{113} = 0.06452$ $f_{114} = 0.06250$ $f_{115} = 0.06452$ $f_{121} = 0.05556$ $f_{122} = 0.05264$ $f_{123} = 0.05556$ $f_{124} = 0.05264$ $f_{125} = 0.05556$	$f_{211} = 0.06896$ $f_{212} = 0.06452$ $f_{213} = 0.06250$ $f_{214} = 0.06250$ $f_{215} = 0.06452$ $f_{221} = 0.05882$ $f_{222} = 0.05556$ $f_{223} = 0.05264$ $f_{224} = 0.05264$ $f_{225} = 0.05556$

Note: f_{ijk} values were determined by distance to the target and required maintenance between missions.

Table 2.3 Military Target Values [28]

Target Set	Scenario 1	Scenario 2	Scenario 3
1. Airfields	40	45	0
2. Fuel Storage Depots	10	15	0
3. Close Support	50	40	45
4. Short Interdiction	0	0	45
5. Command and Control	0	0	10

Figure 2.1 Sample scenario for target allocation problem [28]

The second priority level contains only one objective, the damage objective. The aspiration level for Goal 9 is set equal to zero, and since this objective is maximized, underachievement of the objective is minimized by minimizing the negative deviation variable (n_9). Any overachievement will then be indicated by a non-zero value for p_9 , the measure of total damage inflicted on all targets.

The NLGP model for this problem is:

Find the values of $\bar{x} = (x_1, x_2, \dots, x_{24})$

so as to

minimize $\bar{a} = (p_1 + p_2 + p_3 + p_4 + n_5 + n_6 + n_7 + n_8, n_9)$

subject to

Goal 1 through Goal 9

and $\bar{x}, \bar{n}, \bar{p} \geq 0$.

The discussion of the solution to this target allocation problem will be deferred until later chapters.

2.3 Advantages and Limitations

There is still no single best method for solving nonlinear models, whether they contain a single objective or multiple objectives. Each method has advantages and disadvantages inherent to that method. Some advantages and limitations of the NLGP method are reviewed here [18].

The greatest advantage of the NLGP method over conventional methods is that this method allows the analyst or design engineer to model the problem realistically. Most problems have more than a single objective, and generally, some of these objectives will be conflicting in nature. The objectives of the system do not have to be massaged to fit into some prescribed mold so that a solution can be obtained.

A major advantage of the NLGP method over conventional methods is that a solution to the problem is always obtained. This is due to the direct search technique used in the method and the ordered set of preemptive priority levels. Rather than considering infeasibility, solutions are either implementable (i.e., $a_1 = 0$) or unimplementable (i.e., $a_1 > 0$). The achievement vector indicates the degree to which the desired aspiration levels are met.

In general in nonlinear optimization, there is no way to guarantee that the solution obtained will be a global optimum. The NLGP technique performs no better or worse than other methods in this respect. In actual practice, this technique has proved to be a robust method for the solution of some very complex problems.

The priority structure does have limitations, however. The existence of a preemptive priority structure may not always be a valid assumption. Absolute objectives (i.e., natural laws, limited resources) cannot be violated and belong in the highest priority level. The number and arrangement of objectives in lower priority levels may not be as obvious and can depend upon the analyst, or engineer's understanding and insight into the problem. Quite often some objectives must be switched between priority levels or entire levels rearranged to obtain satisfactory results, especially when little is known apriori about the problem.

The use of weighting factors in the achievement vector is an advantage because these factors enable the analyst or design engineer to weight objectives only within a single priority level. The proper weighting of objectives is not a clearcut procedure, however, and these weights often must be established through an iterative process.

Finally, aspiration levels for some objectives may not always be obvious. Again, proper determination of these levels may have to be accomplished through a number of trials and, in any case, evaluated in the final result via a sensitivity analysis.

CHAPTER III

COMPUTATIONAL TECHNIQUES

3.1 Introduction

A variety of methods can be employed to solve nonlinear models [5,6,7,8,9,10,11,12,27,30]. The success of a method over other methods to find a solution may be relative to the particular problem as well as to initial problem parameters. A straightforward approach for solving large-scale nonlinear models is one employing direct search techniques. The method selected for the nonlinear goal programming technique is based on an extension of the search method of Hooke and Jeeves [12].

The Hooke-Jeeves method is an accelerated pattern search technique. It is based on the assumption that any set of moves which has been successful in optimizing the objectives is worth repeating. The algorithm starts with an initial point (i.e., an n -dimensional vector), perturbs each variable one at a time and tests for an improved solution. When a search has been successful, future increments for the pattern search moves are increased. When a search is unsuccessful in finding an improved solution, future increments are decreased. This pattern search technique has been shown to be a simple and effective method for solving actual problems with large numbers of variables, large number of objectives, and a variety of convergence criteria [12]. It is a simple method which makes it computationally efficient. This makes it attractive for use with the NLGP algorithm.

3.2 The Nonlinear Goal Programming Computer Code

The software package developed under this contract contains three separate computer codes. All three codes can be used to solve an NLGP problem. All three codes are very similar in technique. Each code has some minor modifications which makes it better suited to solve a different variation of NLGP problem. The basic computer code and its operating characteristics will be discussed in detail in this section. The remaining two codes will be discussed in the section covering modifications. All program versions are written in American National Standard FORTRAN IV.

The basic computer code is referred to as the nonlinear goal programming/modified pattern search - ridge search code, NLGP/MPS-RS code. This is Version 1 of the code. A complete listing of this code is contained in Appendix A.

The NLGP/MPS-RS: Version 1 code is composed of a small main program and seven subprograms. Two of these seven subprograms must be supplied in part by the user for each new NLGP problem. Figure 3.1 is a schematic diagram showing the operating relationships of the subprograms.

The MAIN program contains data initialization statements, type declaration statements, and other specification statements that are necessary for the definition of the program parameters and variables. The MAIN program calls subroutine DATAIN and subroutine HJALG, the Hooke-Jeeves pattern search algorithm. Subroutine DATAIN is used to input all problem data. Once this is accomplished, all further control of the program proceeds through subroutine HJALG. Table 3.1 gives a brief description of the modules making up the computer code. Module length is given as compiled on an IBM 370/3033 System using the FORTRAN WATFIV compiler.

Figure 3.1 Program Relationship Diagram -
NLGP/MPS-RS Code: Versions 1
and 2

Table 3.1 Program Module Information NLGP/MPS-RS Code:
Versions 1 and 2

Program Module	No. of bytes (in decimal)	Module Length	Description	Calls	Called By
MAIN Program	632		Serves as executive program for the pattern search	DATAIN HJALG	-----
Subroutine DATAIN	3344		Reads into storage all prob- lem data	-----	MAIN
Subroutine HJALG	6048		Performs pattern search through exploratory and pattern moves	ACHFUN DECIDE RIDGE	MAIN
Subroutine RIDGE	4248		Performs a resolution ridge search when the pattern search no longer moves	ACHFUN DECIDE	HJALG
Subroutine DECIDE	2000		Compares achievement vectors and tests for termination	-----	HJALG RIDGE
Subroutine ACHFUN	Problem Dependent Minimum of 368		Computes the values of the achievement vector	DEVVAR	HJALG RIDGE
Subroutine DEVVAR	680		Computes the values of the positive and negative devia- tion variables	OBJFUN	ACHFUN
Subroutine OBJFUN	Problem Dependent Minimum of 304		Computes the values of the objective functions	-----	DEVVAR
Total:	Minimum of 17624 bytes				

Each subprogram of the code will be discussed in terms of its operation and the program parameters and variables which it uses. The complete FORTRAN language listing of each subprogram is contained in Appendix A. A list of all program variables and parameters is given in Table 3.2. A complete guide on how to select the values of program parameters is contained in the User's Manual.

The computer program is presently dimensioned to handle problems with up to 2500 objectives, 2500 variables, and 10 priority levels. These dimensions can be altered to increase the problem size which can be solved.

Subroutine DATAIN

Subroutine DATAIN is used to input all the necessary data for the NLGP problem. Once this data is read into internal storage, an echo check of this data is printed as a means of checking it. Table 3.3 contains a listing of the data which must be input and its form.

Variables and parameters used in DATAIN:

NOBJ
NPRIOR
NVAR
NMAX
EPS
ACCEL
REDUCE
DELTA
X
LBD
UBD
RHS
EPSY.

Table 3.2 Computer Code Variables and Parameters
NLGP/MPS-RS Code: Version 1

<u>Name</u>	<u>Description</u>
NOBJ	Number of problem objectives
NPRIOR	Number of priority levels in the achievement vector
NVAR	Number of decision variables
NMAX	Maximum number of pattern search cycles allowed before termination; set by user
NCYCLE	Counter of pattern search cycles
X	Decision variable vector for perturbations in pattern search
XBASE	Decision variable base point vector for pattern search
A	Achievement vector at a test point
ABEST	Achievement vector for best solution during pattern search
APOS, ANEG	Temporary achievement vectors for the resolution ridge search
EPS, IPS	Perturbation step-size scalars used for exploratory moves
LBD, UBD	Lower and upper bound vectors on decision variables
OBJ	Objective function vector
RHS	Desired aspiration levels for objectives
N, P	Negative and positive deviation vectors
EPSY	Test vector for termination of algorithm by meeting specified tolerances
ACCEL	Acceleration factor for pattern moves
REDUCE	Step-size reduction factor
DELTA	Minimum allowable step-size for exploratory moves
IMPROV	A test switch; if IMPROV = 1, X improves the solution for ABEST, if IMPROV = 0, X does not improve this solution

Table 3.2 Continued

<u>Name</u>	<u>Description</u>
IPRINT	An output switch; if IPRINT = 1, complete results are printed out at every pattern search cycle, if IPRINT = 0, only the final results are printed.
ITERM	A termination testing indicator; if ITERM = 1, the solution for A is compared to ABEST and then tested for termination against EPSY, if ITERM = 0, only a comparison of A and ABEST is made.
IPROG	A counter for number of improvements, if any, during the exploratory moves
IACCEL	An indicator for pattern moves; if IACCEL = 1, the pattern moves was successful, if IACCEL = 0, no pattern move was attempted, if IACCEL = -1, the pattern move was unsuccessful
SAVE	A temporary storage variable for pattern and ridge moves
I	Counter for all do loops containing the objective functions, OBJ
J	Counter for all do loops containing the priority levels of the achievement vector, A and ABEST
K	Counter for all do loops containing the decision variables, X and XBASE

Table 3.3 Data Input Guide NLGP/MPS-RS
Code: Version 1

<u>Card</u>	<u>Data</u>	<u>Type</u>	<u>Format</u>

7	EPS	Real *4	F10.0
	ACCEL	"	F10.0
	REDUCE	"	F10.0
	DELTA	"	F10.0

Subroutine HJALG

Subroutine HJALG is the Hooke-Jeeves pattern search Algorithm as modified to solve NLGP problems. Figure 3.2 is a schematic diagram showing the flow through the pattern search algorithm. A detailed computer logic flow diagram is contained in Figure 3.3.

Variables and parameters used in HJALG:

NOBJ	IPRINT
NPRIOR	ITERM
NVAR	I PROG
NMAX	IACCEL
NCYCLE	IPS
X	EPS
XBASE	LBD
A	UBD
ABEST	IMPROV
SAVE	
ACCEL	
REDUCE	
DELTA	

Subroutine RIDGE

Subroutine RIDGE is used to calculate a new temporary head point when the exploratory moves of the pattern search fail to find any improved points near the base point, XBASE. RIDGE is a heuristic technique which uses information for each set of pairwise perturbations, positive and negative around a variable $x(k)$. It attempts to move in a direction which is oblique to the original axes of exploration, and therefore, move away from the present base point around which the pattern has collapsed.

The basis for RIDGE comes from Rosenbrock's technique for rotation of coordinates [29] and Muegele's "poor man's optimizer" [26]. RIDGE requires much less storage of information than Rosenbrock's method. It is constructed specifically to use information from the achievement vector to establish a direction for continued search. It is called everytime the step size, IPS,

Figure 3.3 Continued

becomes smaller in value than the minimum allowable step size, DELTA.

Figure 3.4 shows the flow diagram for subroutine RIDGE.

Variables and parameters used in RIDGE:

X	NPRIOR
XBASE	SAVE
IPS	NVAR
EPS	ITERM
LBD	IMPROV
UBD	ACCEL
APOS	
ANEG	
A	
ABEST	

Subroutine DECIDE

Subroutine DECIDE has two main purposes: (1) To compare the achievement vector at a test point, A, against the achievement vector for the best point, ABEST. If A is preferred over ABEST, it becomes ABEST and the corresponding x vector, X, becomes XBASE, the new base point. If A is not preferred over ABEST, the program continues with no changes to the variables. and (2) To test the achievement vector for termination of the algorithm. Termination can occur by two methods: first, all elements of the achievement vector have zero values; this is an optimal solution, and secondly, when all elements of the achievement vector have values less than the specified tolerance vector, EPSY. This is the test by tolerances. Figure 3.5 is the flow diagram for subroutine DECIDE.

Variables and parameters used in DECIDE:

A
ABEST
NPRIOR
IMPROV
ITERM
X
EPSY

Figure 3.4 Flow Diagram for Subroutine Ridge

Figure 3.4 Continued

Figure 3.4 Continued

Figure 3.5 Flow Diagram for Subroutine DECIDE

Figure 3.5 Continued

Subroutine ACHFUN

Subroutine ACHFUN is the module which contains the functions of weighted positive and negative deviation variables. These functions must be supplied by the user for each new NLGP problem. An example will be presented in the next chapter which will show these functions, one for each priority level in the achievement vector. Figure 3.6 shows the computer flow diagram for this subroutine.

Variables and parameters used in ACHFUN:

A
N
P

Subroutine DEVVAR

Subroutine DEVVAR calculates the values of the negative and positive deviation variables. It uses the values of the objective functions already calculated and compares these values to the desired aspiration levels, RHS. Figure 3.7 shows the flow diagram.

Variables and parameters used in DEVVAR:

NOBJ
OBJ
RHS
N
P

Subroutine OBJFUN

Subroutine OBJFUN is used to calculate the values of the objective functions at the test point x. These functions must be user supplied for each new NLGP problem to be solved. An example of this subroutine will be presented in the next chapter. A flow diagram of this subroutine is contained in Figure 3.8.

Variables and parameters used in OBJFUN:

OBJ
X

3.3 Modifications

The second and third versions of the NLGP/MPS-RS code are modifications of version 1. The modifications which make them different from the basic code are presented here. Otherwise, these codes are exactly the same as version 1. Complete FORTRAN language computer listings of these versions are contained in Appendices B and C.

The NLGP/MPS-RS: Version 2 Code

This computer code is exactly like version 1 except that the perturbation step sizes, EPS and IPS, are vectors instead of scalars. This enables the user to input a separate step size for each variable. This can be especially important when the range of values which the variables can take on vary considerably.

The major difference in the code from version 1 is in subroutine DATAIN. Now a vector of values for EPS must be read into storage. Table 3.4 lists the necessary cards for input for version 2.

Minor modifications also appear in subroutines HJALG and RIDGE. All statements previously using IPS and EPS now use the variable forms, IPS(k) and EPS(k). The resetting of the step size vector in subroutine RIDGE is accomplished using a do loop of the form:

```
DO 10 K=1, NVAR
  IPS(k) = EPS(k).
```

Advantages for using this version as compared to the other versions will be presented in the next section.

The NLGP/MPS-RS: Version 3 Code

Version 3 of the computer code is the same as version 2 with an additional subroutine, subroutine UVALUE. This subroutine has been added to reduce the computation time necessary for the evaluation of the objective functions.

Table 3.4 Data Input Guide NLGP/MPS-RS
Code: Version 2

<u>Card(s)</u>	<u>Data</u>	<u>Type</u>	<u>Format</u>
1	NOBJ	Integer *4	I5
	NPRIOR	"	I5
	NVAR	"	I5
	NMAX	"	I5

8	ACCEL	Real *4	F10.0
	REDUCE	"	F10.0
	DELTA	"	F10.0

Whenever a new test point, X, is formed, subroutine OBJFUN is eventually called to evaluate all the objectives at this test point so that a new achievement vector can be formed. There are many cases, however, when it is not necessary to re-evaluate all the objective functions.

There are two reasons for this:

- (1) Many problems have objectives which are sparsely populated by the variables. It is not necessary to re-calculate all the objectives when the variable being perturbed only appears in a few of the objectives, and
- (2) Since the pattern search algorithm perturbs one variable at a time during exploratory moves, it is not necessary to re-calculate every term in each objective function. Rather, only those terms in which the perturbed variable appears need to be recalculated, and the net effect on the value of the objective function can be determined.

Both categories occur frequently in large-scale nonlinear problems. The use of the UVALUE subroutine eliminates many unnecessary calculations. This results in significant reductions in computation time, especially in large problems. The subroutine can be especially useful during the exploratory moves.

Additionally, this subroutine is problem dependent and must be supplied in part by the user for implementation with the code. A flow chart description of subroutine UVALUE is given here for the target allocation problem described in Chapter II. A complete description of the use and set-up of this subroutine is contained in the User's Manual.

The major modifications contained in this code will now be presented. The new parameters and variables which are contained in version 3 are listed in Table 3.5. Their use in the program will be indicated through flow charts showing the revised subroutines.

Subroutine DATAIN

Subroutine DATAIN is exactly the same as that used in version 1 with one addition. The matrix of coefficients, $AMAP(M,L)$ must be read into storage. It is currently dimensioned to (100,100). Larger problems could be solved by increasing this matrix in subroutine UVALUE and DATAIN. Table 3.6 shows the revised data input guide for version 3.

Subroutine HJALG

Subroutine HJALG in version 3 differs from that in version 1 in that it now calls subroutine UVALUE instead of subroutine OBJFUN in many places in the program, as indicated by the switch, JPI. Subroutine OBJFUN is called initially to calculate the values of the objective functions. During the exploratory moves, subroutine UVALUE is used to calculate the incremental changes in the objective functions for the variable being perturbed. The additional variables and parameters used in subroutine HJALG are:

JPI
LNUM
UVALUE
SEPS.

The complete flow diagram for this subroutine is in Figure 3.9.

Subroutine RIDGE

Same as in version 1.

Subroutine DECIDE

Same as in version 1.

Figure 3.9 Continued

Subroutine ACHFUN

Same as in version 1 (problem dependent).

Subroutine DEVVAR

This subroutine is slightly different, in that it now tests to see if subroutine OBJFUN is UVALUE is to be called, then calls the appropriate one. Figure 3.10 shows the flow diagram for this subroutine.

Subroutine OBJFUN

Same as in version 1 (problem dependent).

Subroutine UVALUE

This subroutine calculates the incremental changes in the objective functions. The variables and parameters used in this subroutine are:

NOBJ	SEPS
L	A,B,C,D,E
LNUM	Y9
DIFF	
AMAP	

Calls to other subroutines: None.

The flow diagram for this subroutine is contained in Figure 3.11. It should be restated that this subroutine has many statements which are problem dependent, and those shown in the flow diagram represent a schematic for the objectives used in the target allocation problem of Chapter II. A more thorough discussion of the formulation of this subroutine is given in the User's Manual.

Further discussion of the three versions and their respective advantages and limitations will be given in the following sections of Chapter III.

Figure 3.10 Flow Diagram for Subroutine DEVVAR:
Version 3

Figure 3.11 Flow Diagram for Subroutine UVALUE

Figure 3.11 Continued

Figure 3.11 Continued

3.4 Specifications

Each version of the code has different computer storage specifications, due to the modifications contained in versions 2 and 3. All three codes are presently dimensioned for problems of the following maximum size:

Number of objectives	= 2500
Number of variables	= 2500
Number of priority levels	= 10 .

The computer core storage necessary for each version of the code will be dependent upon the number and type of objective functions and the number of and term in the achievement vector. If every variable appears in every objective function, the core storage necessary for subroutine OBJFUN could be conservatively estimated to be:

$$\begin{aligned} & (80 \text{ Bytes/card}) \times (1 \text{ card}/10 \text{ variables}) \times (2500 \text{ variables}) \\ & = 20,000 \text{ Bytes/objective} \\ & (20,000 \text{ Bytes/objective}) \times (2500 \text{ objectives}) \\ & = 50 \text{ million Bytes.} \end{aligned}$$

This is an estimated minimum storage requirement if all variables appear in all objectives. Since most problems do not have this form, actual storage will be much smaller. Table 3.7 gives the requirements which are minimum values, and actual requirements will vary greatly depending on the problem.

3.5 Advantages and Limitations

There are advantages to using each code which depend on the type of problem to be solved. Version 1 is the basic code, the simplest in form, and the easiest to use. This code is differentiated from the other two versions in that it uses a scalar for the step size, EPS, for the perturbations in the exploratory moves. This is advantageous when the decision

Table 3.7 Storage Requirements

Bytes (in decimal)		
<u>Version</u>	<u>Object Code</u>	<u>Array Area</u>
1	22,016	80,260
2	22,016	90,260
3	22,784	130,308

variables for the problem are all similar in nature and in the range of values which they can have. Using the scalar step size saves 10,000 bytes of core storage. This area can be used to redimension the number of variables to sizes larger than 2500.

Version 1 is limited in this same respect if the range of values for the variables vary greatly or if their very nature makes it difficult to select only a single step size for the exploratory moves. This disadvantage is eliminated by the use of version 2. With a vector of step sizes, each variable can have a distinct step size to account for the type and range of values peculiar to it. This results in an additional cost of 10,000 bytes of core storage, but only a negligible increase in computation time.

The third version of the code is the most complex, and therefore, the most difficult for the user to implement. All codes must have user supplied subroutines OBJFUN and ACHFUN, but version 3 also requires a user supplied subroutine UVALUE. This is the most difficult subroutine to formulate. Its advantages of saving considerable computer time offsets the disadvantages of its additional storage requirements and difficulty of use only when the problem to be solved is large (i.e., in the range of 1000 or more variables and 500 or more objectives) and when only a few variables appear in each objective. It is the opinion of the authors that the use of version 3 be attempted only after the user has gained experience using versions 1 and 2, and also has a thorough understanding of the problem to be solved.

The direct search technique utilized in each version is superior to gradient search techniques in the number and type of evaluations which must be made to calculate an achievement vector. No gradients have to be calculated or estimated through expansion of series.

This technique is limited in that one can only hope to obtain a local optimal for the problem solution, especially for large and complex problems. (Global optimal solutions can be obtained, however, when the problem is of a special nature and limited complexity.)

Finally, the computer codes are designed to find solutions which are continuous - valued in nature. Problems which require solutions with 0-1 valued variables and mixed integer-continuous problems present special difficulties. No guarantee can be made that the solutions obtained will be integer valued. Some attempt can be made to control the variable values by restricting the lower and upper bounds and restricting the step size used for variable perturbations.

More comments on these considerations will be made in the final chapter.

3.6 Summary

Three different versions of the NLGP/MPS-RS computer code have been developed. Each version has advantages over the others which makes it superior for solving a particular type or class of NLGP problems.

A brief description has been given for each code, explaining its general form and the types of variables and parameters used in each. Flow diagrams depict the subroutines composing each code, and an overall flow schematic shows the relationships of these subroutines to form an entire computer program. Listings for each are given in Appendices A, B, and C.

Some general advantages and limitations for the use of each version have been described. More specific information detailing the implementation of each code can be found in the User's Manual supplied along with this report. Considerations on problem solution and computational aspects will be given in Chapter IV.

CHAPTER IV

COMPUTATIONAL RESULTS

4.1 Introduction

The general nonlinear goal programming problem formulation was presented in Chapter II along with an example. The three variations of the computational techniques used to solve such an NLGP problem were described in Chapter III. The solution to the example problem will be presented here first, and then the remainder of this chapter will discuss computational results in general.

4.2 A Target Allocation Problem: Solution

The target allocation problem formulated in Chapter II is a small-scale problem, but it shows a type of problem suitable to naval application. The NLGP model for this problem is:

Find the values of $\bar{x} = (x_1, x_2, \dots, x_{24})$ so as to minimize
 $\bar{a} = (p_1 + p_2 + p_3 + p_4 + n_5 + n_6 + n_7 + n_8, n_9)$ subject to:

Aircraft availability objectives

$$\text{Goal 1: } x_1 + x_3 + n_1 - p_1 = 27$$

$$\text{Goal 2: } x_2 + x_4 + n_2 - p_2 = 102$$

Carrier space objectives

$$\text{Goal 3: } 2920 x_1 + 1770 x_2 + n_3 - p_3 = 112,300$$

$$\text{Goal 4: } 2920 x_3 + 1700 x_4 + n_4 - p_4 = 147,100$$

Limitations on missions due to aircraft availability

$$\begin{aligned} \text{Goal 5: } & x_1 - 0.6452 (x_5 + x_7 + x_9) - 0.06250 (x_6 + x_8) \\ & + n_5 - p_5 = 0 \end{aligned}$$

$$\begin{aligned} \text{Goal 6: } & x_2 - 0.05556 (x_{10} + x_{12} + x_{14}) - 0.05264 (x_{11} + x_{13}) \\ & + n_6 - p_6 = 0 \end{aligned}$$

$$\begin{aligned} \text{Goal 7: } & x_3 - 0.06896 x_{15} - 0.06452 (x_{16} + x_{19}) \\ & - 0.06250 (x_{17} + x_{19}) + n_7 - p_7 = 0 \end{aligned}$$

$$\begin{aligned} \text{Goal 8: } & x_4 - 0.05882 x_{20} - 0.0556 (x_{21} + x_{24}) \\ & - 0.05264 (x_{22} + x_{23}) + n_8 - p_8 = 0 \end{aligned}$$

Damage objective

$$\begin{aligned} \text{Goal 9: } & 40 (1 - 0.99978 (x_5 + x_{15}) 0.99953 (x_{10} + x_{20})) \\ & + 10 (1 - 0.99978 (x_6 + x_{16}) 0.99953 (x_{11} + x_{21})) \\ & + 50 (1 - 0.99978 (x_7 + x_{17}) 0.99953 (x_{12} + x_{22})) \end{aligned}$$

$$\text{and } \bar{x}, \bar{n}, \bar{p} \geq 0$$

This problem has the following specifications for the computer codes:

$$\begin{aligned} \text{NOBJ} &= 9 \\ \text{NVAR} &= 24 \\ \text{NPRIOR} &= 2. \end{aligned}$$

The objectives are divided into two groups for the priority levels. Priority level one contains the first eight objectives. These are resource objectives which cannot be violated. The second priority level measures the damage inflicted on all targets by the aircraft from the two aircraft carriers. The reader is referred to Chapter II for a complete description of all problem parameters.

Table 4.1, 4.2, and 4.3 list all the input information necessary for the solution of this problem. Table 4.1 contains the program parameters necessary for control of the pattern search. Table 4.2 contains data related to the variables, and Table 4.3 contains the data as related to the objectives and achievement vector.

The solution to this problem is given in Table 4.4. The achievement vector element $a(1) = 0.0$ indicates that the first eight objectives (i.e., constraints) have all been satisfied. The second element $a(2)$ measures the total damage to enemy targets in terms of the military value placed on each target set. The maximum attainable damage would be 100 units. The value $a(2) = 67.55$ is the underachievement from this maximum aspiration level. Thus, the difference $(100 - 67.55) = 32.45$ units is the measure of total damage inflicted on all enemy targets.

The decision variables represent the best solutions for $\bar{x}$ to attain the values of $a(1)$ and $a(2)$. The reader is referred to Table 4.5 for the conversion of the solution to the actual problem variables.

The solution which has been calculated has continuous values for the decision variables. The nature of the problem and the variables demands that they be integer values. All non-integer values appear to be the result of round-off errors in the calculations. The solution at integer values rounded to the next closest value is:

$$\begin{aligned}a(1) &= 0.0 \\a(2) &= 67.71\end{aligned}$$

This results in a military value for the damage of 32.29, which is slightly less than the continuous solution and differs by 0.49 percent. The computer code gives an acceptable, if not exact, solution to the NLGP problem.

Table 4.1 Input Data for Program Parameters:
Target Allocation Problem

Number of Objectives =	9
Number of Priorities =	2
Number of Decision Variables =	24
Maximum Number of Allowable Pattern Search Cycles =	50
Initial Step Sizes =	2.0000
Acceleration Factor =	2.0000
Step Size Reduction Factor =	0.5000
Minimum Allowable Step Size =	0.0001

		y_{225}	8.999

Anytime a problem is encountered which must have an integer solution for some of the variables, the non-integer values can be rounded to integer values and resolved for a problem solution. This method cannot guarantee that a better integer solution does not exist. This method should result in a solution which is close in value to the best continuous solution to the problem. It also yields a good starting point for the examination of other integer solutions.

For comparison, Rice, et al [28] obtained similar results for the total damage inflicted using SUMT [5]. Using the target values for scenario 1, their solution had 33.67 percent of the total target value damaged, as compared to 32.45 percent using the NLGP method. They obtained assignments of 9 aircraft of type 1 and 69 aircraft of type 2 to carrier 2. Unfortunately, this solution violates the carrier space availability constraint for carrier 2 (148,410 ft² used versus 147,100 ft² available). This makes their solution infeasible. The NLGP solution, although slightly smaller in value for the damage percentage, is better since it does yield a feasible solution. No priority level one objectives (i.e., resource constraints) were violated. The authors feel that in more complex and large problems, the superiority of the NLGP method over single objective methods will be more pronounced.

4.3 Empirical Results

The relationship of problem size (i.e., the number of objectives and number of variables) versus computation time and storage requirements has been examined. The results of many problems which were solved will be presented on an aggregate level.

Testing of the three computer codes proceeded from an initial phase where problems were small and simple in nature to a secondary phase to the final phase where problem size exceeded 100 variables and 100 objectives.

In the initial phase, a number of problems with less than 10 objectives and 10 variables were solved. The second phase of testing involved problems ranging in size from 10 to 25 objectives and 25 to 75 variables. The last phase involved problems with over 100 objectives and over 100 variables. A summary of the results is in Table 4.6.

The average compilation time increases because the object code increases with problem size and complexity. This is because the user supplies sub-routines OBJFUN and ACHFUN (and UVALUE, if version 3 is used). These will vary in size by problem.

The average execution time of course increases with increases in problem size. It is interesting that the difference between the last two categories is slight. This is due in part to the fact that the problems with greater than 100 objectives and 100 variables had primarily linear objectives (usually 100) and only a few nonlinear objectives (10 to 20). This made execution of these problems much faster than would normally be expected with the majority being nonlinear objectives.

Computer storage versus problem size is a difficult relationship to predict. The array area is fairly constant as would be expected, since this area depends on the dimensioning within the program. The object code sizes varied and tended to increase with increases in problem size. This storage requirement will be highly dependent on the type of objectives (i.e., linear versus nonlinear), complexity of the objectives (i.e., quadratic terms, exponential terms, logarithmic terms), the number of terms in each objective, and the number of objectives in the problem. These areas will dictate storage requirements, and also, execution time.

Table 4.6 Computation Results

Problem Size	TIME (SECONDS)			STORAGE (BYTES)	
	Average Compile Time	Average Execution Time	Range Execution Time	Object Code (AVE)	Array Area (AVE)
NOBJ<10 NVAR<10	0.230 secs.	0.064 secs.	0.04 - 0.11 secs.	17476 Bytes	80260 Bytes
NOBJ<25 25<NVAR<50	0.248	1.217	0.64 - 2.11	22746	80260
NOBJ<25 50<NVAR<75	0.349	9.591	1.72 - 17.32	18062	86473
100<NOBJ<150 100<NVAR<150	0.930	10.260	9.56 - 11.44	47931	80260

Note: All jobs were run on an IBM i70/3033 system using the FORTRAN WATFIV compiler.

4.4 Summary

All three codes have been tested and give the same solutions to the same problems. Execution times of the programs are fairly equivalent for all three codes. Version 3 had no particular advantage over the others for the problems on which it was tested, but those problems were deemed too small to show appreciable advantages. Version 3 should give substantial savings in the area of execution time over versions 1 and 2 when the problem size is large and the objectives are sparsely populated by the variables.

Version 1 is the least complicated of the three codes and easiest to use. Version 2 is the next in line in terms of ease of access. Version 3 is the most difficult to set up for computation due to subroutine UVALUE. Its advantages have already been mentioned.

CHAPTER V

CONCLUSIONS

5.1 Conclusions

The specific objectives of this study have been met. To meet the demands for a general computer tool to solve a broad range of NLGP problems, three computer codes have been developed. Each has advantages over the others which make it superior for solving certain types of problems.

A detailed User's Manual has been supplied along with this report and copies of the codes. The User's Manual is the guide on how to use each of the codes. It gives example problems, examples of the necessary computer input, aids for selection of this information, examples of the output, and its analysis.

5.2 Recommendations

The present NLGP algorithm and computer codes have limitations which have been presented in previous sections. There are certain areas in which future research efforts should be focused:

- (1) Examination and development of other heuristic techniques to solve 0-1 nonlinear goal programming problems.
- (2) Development of methods to solve mixed-integer NLGP problems.
- (3) Development of generalized sensitivity analyses for NLGP and implementation of these methods into computer packages.
- (4) Analysis of these and future codes using actual design problems with over 1,000 variables and over 1,000 objectives.
This will greatly enhance future validation efforts.
- (5) Including and testing future additional program modifications as they are developed.

 C NONLINEAR GOAL PROGRAMMING--PATTERN SEARCH CODE
 C *****

THIS IS THE NLGP/MPS-PS NAVY CODE
 NONLINEAR GOAL PROGRAMMING/PRINCIPAL PATTERN SEARCH CODE
 WITH A RESOLUTION RIDGE SEARCH TECHNIQUE
 VERSION 3: SUBROUTINE UVALUE
 --- JULY 15, 1980 ---

CODE SPECIFICATIONS

2500 OBJECTIVES
 2500 VARIABLES
 10 PRIORITY LEVELS

VARIABLES AND PARAMETERS

NAME	***DESCRIPTION***
NCEJ	NUMBER OF OBJECTIVES
NPRIOR	NUMBER OF PRIORITY LEVELS
NVAR	NUMBER OF DECISION VARIABLES
NMAX	MAXIMUM NO. OF PATTERN SEARCH CYCLES ALLOWED
NCYCLE	COUNTER FOR PATTERN SEARCH CYCLES
X	DECISION VARIABLE VECTOR USED FOR PERTURBATION
XBASE	BASE POINT VECTOR FOR PATTERN SEARCH
A	ACHIEVEMENT VECTOR AT TEST POINT
ABEST	ACHIEVEMENT VECTOR FOR BEST SOLUTION
APCS,ANEQ	TEMPORARY ACHIEVEMENT VECTORS FOR RIDGE SEARCH
EPS,IPS	SCALARS OF PERTURBATION STEP SIZES USED FOR EXPLORATORY MOVES
LBD,UBD	LOWER AND UPPER BOUND VECTORS FOR DECISION VAR
OBJ	OBJECTIVE FUNCTION VECTOR
RHS	RIGHT-HAND SIDE VALUE VECTOR FOR OBJECTIVE FNS
N,E	NEGATIVE AND POSITIVE DEVIATION VARIABLE VECT.
EPSY	TERMINATION TOLERANCE TEST VECTOR
ACCEL	ACCELERATION FACTOR
REDUCE	STEP SIZE REDUCTION FACTOR
DELTA	MINIMUM ALLOWABLE STEP SIZE
IMPROV	TEST SWITCH---IF IMPROV=1, X IMPROVES THE SOLUTION; IF IMPROV=0, X DOES NOT IMPROVE THE SOLUTION
IPRINT	OUTPUT SWITCH---IF IPRINT=1, RESULTS ARE PRINTED OUT AT EVERY PATTERN SEARCH CYCLE; IF IPRINT=0, ONLY THE FINAL RESULTS ARE OUTPUT
ITERM	TERMINATION TEST SWITCH---IF ITERM=1, THE SOLUTION IS TESTED FOR TERMINATION; IF ITERM=0 ONLY A COMPARISON TEST IS PERFORMED
IPFCG	COUNTER FOR IMPROVEMENTS DURING THE EXPLICIT MOVES
IACCEL	INDICATOR FOR ACCELERATION MOVES: IACCEL = 1, ACCELERATION MOVE WAS SUCCESSFUL IACCEL = -1, ACCELERATION MOVE WAS UNSUCCESSFUL IACCEL = 0, ACCELERATION MOVE WAS NOT ATTEMPTED
SAVE	A TEMPORARY SWITCHING INDICATOR FOR PATTERN AND RIDGE MOVES
JPI	INTERNAL CONTROL PARAMETER FOR SUBROUTINE UVALUE---IF JPI=0, THEN UVALUE IS NOT USED; IF JPI = 1, UVALUE IS USED TO EVALUATE THE OBJECTIVE FUNCTIONS USING THE EXPLORATORY PERTURBATIONS

C AMAP MATRIX OF OBJECTIVE FUNCTION COEFFICIENTS
 C DIFF DIFFERENCES BETWEEN OBJECTIVE FUNCTION VALUES
 C FOR THE BEST POINT AND THE CURRENT TEST POINT
 C LNUN INDEX OF VARIABLE BEING TESTED AT
 C EXPLORATORY SEARCH
 C SEPS DIRECTIONAL STEP SIZE SCALAR-IPS---IF POSITIVE
 C DIRECTION EXPLORATORY MOVE, SEPS=IPS; IF NEGA-
 C TIVE DIRECTION EXPLORATORY MOVE, SEPS=-IPS
