Summary. An octa-azamacrocyclic with a 28-membered ring has been found to be capable of incorporating a symmetrical copper-copper bonded unit which contains a short Cu-Cu bond (2.445(4) Å). The compound is paramagnetic with $\mu_{\text{eff}} = 1.87 \mu_B$ at 300 K and exhibits single lines at $g = 2.09$ in the X-band EPR spectra of solid samples or of frozen acetonitrile solutions (77 K).

A number of dinucleating ligands have been used^{1,2} recently to bring two copper atoms into close proximity, thus providing models for the 'Type 3 Coppers' in the multi-copper oxidases.³ These copper sites are characterized³ by an ability to act as two-electron acceptor/donor systems, and contain two Cu^{2+} ions which are strongly antiferromagnetically coupled. In most of these model systems the two copper atoms are separated by bridges containing one¹ or more² atoms. We report here the preparation of a dinuclear complex which contains a direct Cu-Cu bond.

Treatment of a suspension of the octa-aza macrocycle (1)⁴ in tetrahydrofuran with a methanolic solution of copper(II) perchlorate resulted in almost complete dissolution of (1). After filtration the green solution slowly deposited green prisms of the title complex $[\text{Cu}_2(1)](\text{ClO}_4)_3$. The presence of a tricationic complex was unexpected, and could have arisen either (1) by transfer of a single electron to the dicopper centre, (2) by loss of one of the anilino protons from the ligand (a common form of co-ordination for related tetra-aza macrocycles),⁵ (3) by reduction of the copper ions and simultaneous mono-oxidation of the macrocyclic ligand, or (4) from a bonded pair of copper(II) ions with a reduced ligand. The second possibility can be excluded on the basis of an X-ray structure determination which shows that all four anilino nitrogen atoms have approximately tetrahedral geometry (figure 1), rather than a trigonal planar arrangement which has been found⁶ for the deprotonated anilino nitrogen atoms in the neutral complexes (2).

A magnetic moment determination by the Faraday method on a solid sample at room temperature (300 K) yielded $\mu_{\text{eff}} = 1.87 \mu_B$, thus confirming the expected paramagnetism of the $[\text{Cu}_2(1)]^{3+}$ formulation.

The two copper atoms have very similar coordination geometries (table 1) and the cation has approximate 2-fold symmetry about an axis which passes through the midpoint of the Cu-Cu bond and relates the ligand portion a to c and b to d (see figure 1). The similarity of the environments of Cu(1) and Cu(2), and the short bond (2.445(4) Å) between them suggest that the copper atoms should not be assigned discrete formal oxidation states +1 and +2, but that the single unpaired electron is delocalised over both metal centres, or that the metal centres are identical and the unpaired electron resides on the ligand.

The EPR spectra at X-band of a powdered sample or of a frozen acetonitrile solution (77 K) exhibited one line at $g = 2.09$ with a peak line width of 80-90 gauss. These data do not unambiguously support the immediate conclusions from the X-ray structural study that the copper ions are equivalent and that this is a Type IIIA mixed valence compound.⁷ The single line could arise from exchange narrowing between sites with life times which are very short on the EPR time scale, or from inherently narrow lines arising from isotropic nuclear hyperfine coupling constants on the order of $40 \times 10^{-4} \text{ cm}^{-1}$, as estimated from the line width. Such small coupling constants are known for the "blue" copper proteins³ as well as a variety of typical coordination compounds of copper(II).⁸ It is well established that 4s and 4p orbital admixture into the ground state leads to small hyperfine coupling constants⁹ and single line EPR spectra. The magnetic susceptibility and EPR data clearly indicate that the formulation of the compound as $[\text{Cu}_2\text{L}](\text{ClO}_4)_3$ is correct, and the X-ray structural results are most readily interpreted in terms of a copper-copper bond since the Cu-Cu distance is very short¹⁰ for a dinuclear complex, and compares with values found in other metal-metal bonded systems.

An ESCA spectrum was obtained with a PHI 548 spectrometer using a magnesium anode and precision energy analyzer. A single copper $2p_{3/2}$ line at 935.6 eV and a $2p_{3/2}-2p_{1/2}$ separation of 20.3 eV are compelling pieces of evidence for the assignment of like oxidation states to the two copper ions.

The compound undergoes facile reduction rapidly in a variety of solvents including tetrahydrofuran-methanol solutions, but is relatively stable in acetonitrile, thus permitting a range of electrochemical and optical studies on a uniquely new chemical system.

Crystal data $[\text{Cu}_2(\text{l})](\text{ClO}_4)_3$, $\text{C}_{36}\text{H}_{40}\text{N}_8\text{Cl}_3\text{Cu}_2\text{O}_{12}$, $M = 1010.2$, monoclinic, Cc , $a = 22.577(7)$, $b = 11.016(4)$, $c = 20.909(8)$ Å, $\beta = 118.96(2)^\circ$, $V = 4550.0$, $Z = 4$, θ -range $3-35^\circ$ $R = 0.080$ for 1815 data with $I/\sigma(I) > 3.0$, obtained on a Philips PW 1100 diffractometer with Mo-K_α radiation (two of the perchlorate ions show extensive disorder).[†]

We thank the S. R. C. for a studentship (to KPD) and for diffractometer equipment and computing facilities. This work was supported in part by the Office of Naval Research.
