INTRODUCTION

This flood plain information report on the Cuyahoga River from Akron-Peninsula Road to the Summit-Portage County Line has been prepared at the request of the Ohio Department of Natural Resources and the Tri-County Regional Planning Commission. It will be distributed to local interests through the above agencies.

The objective of this report is to provide data that can be used as a guide by planners and local officials for effective and workable legislation in the control of land use within the flood plain. This report includes technical information on the largest known floods of the past and presents data on possible future floods, such as, the Intermediate Regional Flood and the Standard Project Flood. The Intermediate Regional Flood has a frequency of occurrence in the order of once in 100 years. Over a long period of 500 years, the magnitude of this flood would probably be equalled or exceeded five times, or on the average of once every 100 years. A flood of this magnitude is simply defined as having a one percent chance of being equalled or exceeded in any given year. On most streams in Ohio the Standard Project Flood is a flood of very rare occurrence and is larger than any flood that has occurred in the past. The area referred to as a flood plain in this report is the area that would be inundated by the Standard Project Flood. The frequency of occurrence of the Standard Project Flood is more rare than once in 500 years. When valuable development is planned within the flood plain, the levels of possible future floods, including the Standard Project Flood, should be considered.

This report is based on hydrological facts, historical and recent floods heights, and technical data having a bearing on the occurrence and magnitude of floods within the study area.

Maps, profiles, photographs, and valley cross sections are included in this report. From the maps, profiles, and cross sections the depth of probable flooding at any location from a recurrence of one of the past floods or by the future occurrence of either the Intermediate Regional

Flood or the Standard Project Flood may be determined. If properly used these data can be very beneficial in wise flood plain management. From this information, future construction should be planned high enough to avoid flood damages. If new construction must be placed at lower elevations, the chances and hazards of flooding should be recognized. Both the risks involved and available alternatives should be considered.

This report does not include plans for the solution of flood problems. However, it is intended to provide the basis for further study and planning on the part of local governments within the study area. Future flood damages can be reduced by local planning programs which guide and control essential developments in the flood plain through zoning, building codes, health regulations and other regulatory methods. Another means in which local flood plain management can be accomplished is through the public acquisition of land for a low flood damage use such as recreation.

Pamphlets and guides pertaining to flood plain regulations, flood proofing of structures, and other related actions have been prepared by the Corps of Engineers and are made available to State agencies, local governments and citizens in planning who are taking action to reduce potential flood damage.

The Buffalo District of the Corps of Engineers will provide technical assistance to Federal, State and local agencies in the interpretation and use of the information contained within this report. Information such as high water mark elevations, bench marks, and sample flood plain regulations is available. Requests for technical assistance should be coordinated through the Ohio Department of Natural Resources, Division of Water, 815 Ohio Departments Building, 65 South Front Street, Columbus, Ohio 43215.

SUMMARY OF FLOOD SITUATION

This flood plain information study covers the area along the Cuyahoga River from the Akron-Peninsula Road bridge, stream mile 40.25, to the Summit-Portage County Line, stream mile 52.65. Within the 12.4-mile study area the Cuyahoga River flows through the cities of Akron, Cuyahoga Falls, and Stow and the villages of Silver Lake and Munroe Falls.

All of these communities are in Summit County and their locations are shown on plate I. The study area is approximately 30 miles south of Cleveland.

Presently there are eight U. S. Geological Survey water-stage recording stations in the Cuyahoga River basin. The locations of these gaging stations are shown on plate I. The closest gaging station to the study area is at Old Portage located 230 feet upstream of the Akron-Peninsula Road bridge about four miles northwest of Akron. This station measures the flow from a drainage area of 404 square miles. Records published by the United States Geological Survey are available for this station from September 1921 to December 1935 and from March 1939 to the present.

Local government officials and property owners adjacent to Cuyahoga River have been interviewed, and newspaper files and historical documents have been searched for information concerning past floods. From these data and studies of possible future floods on the Cuyahoga River, both the past and future flood situation has been developed.

HISTORICAL FLOOD - Historical documents show that there was severe flooding March 1913 and on 28 June 1924. An estimated stage of 12.0 feet at the Old Portage gage occurred in March 1913. On 28 June 1924 the stage at the gage reached 10.0 feet.

THE GREATEST FLOOD - The greatest known flood recorded on the Cuyahoga River at the Old Portage gage occurred on 21 January 1959. Based on existing development, its peak flow at the Old Portage gage has a frequency of occurrence in the order of once in 200 years.

OTHER GREAT FLOODS - High water and damage in the study area have also occurred on the following dates: 10 February 1959, 26 January 1952, 16 November 1955, and 8 July 1957.

INTERMEDIATE REGIONAL FLOOD - The Intermediate Regional Flood is a flood that has an average frequency of occurrence in the order of once in 100 years. As shown on plates 8 through 10, the January 1959 flood averages 0.6 foot higher than the Intermediate Regional Flood in the area downstream of the confluence of the Little Cuyahoga River. Upstream of Cuyahoga Falls, the Intermediate Regional Flood averages one foot higher than the January 1959 flood. Peak discharges during an Intermediate Regional Flood on the Cuyahoga River are estimated as 5,820 cfs at the Old Portage gage and 5,300 cfs upstream of the confluence of Little Cuyahoga River. Table I compares the Intermediate Regional and Standard Project Floods with the January 1959 floods at selected locations in the study area.

STANDARD PROJECT FLOOD - The Standard Project Flood is a flood resulting from a severe combination of meteorological and hydrological conditions that is considered reasonably characteristic of the drainage basin under study. The Standard Project Flood is not assigned a frequency although it is more rare than once in 500 years. Its water surface is considered by the Corps of Engineers to be the upper limit of the flood plain. Estimated Standard Project Flood discharges and stages at selected locations are listed on table I.

FLOOD DAMAGES - The recurrence of major known floods such as the 1913, 1952, and 1959 floods would result in substantial damage in the study area. An occurrence of the Standard Project Flood would cause extensive damage within the flood plain because of greater depths of flooding and accompanying higher velocities.

MAIN FLOOD SEASON - The greatest floods of record in the Cuyahoga River basin occurred in March 1913, June 1924, January 1952, November 1955, and January 1959. Flooding can occur in any month of the year. Flooding

TABLE I

RELATIVE FLOOD HEIGHTS ON THE CUYAHOGA RIVER

Location	Mile Above Mouth	Flood	Estimated Peak Discharge (cfs)	Above or below Jan. 1959 Flood (feet)
Akron-Peninsula Rd. bridge (Downstream limit of study)	40.25	January 1959 Intermediate Regional Standard Project	6,500 5,820 41,100	-- - 0.7 + 10.9
Cuyahoga St. bridge	42.77	January 1959 Intermediate Regional Standard Project	4,400 5,300 35,400	-- + 0.4 + 14.0
Broad Blvd. bridge	46.37	January 1959 Intermediate Regional Standard Project	4,400 5,300 35,400	-- + 1.0 + 24.0
Summit-Portage County Line (Upstream limit of study)	52.65	January 1959 Intermediate Regional Standard Project	4,400 5,300 32,500	-- + 0.6 + 14.8

during the winter and spring months is normally the result of melting snow accompanied by moderate amounts of rainfall. Intense local thunderstorms during the summer and fall can also produce flooding.

FLOOD DAMAGE PREVENTION MEASURES - In March 1964 the Corps of Engineers submitted an unfavorable reconnaissance report for flood control on the Cuyahoga River in the vicinity of Cuyahoga Falls, Silver Lake and Munroe Falls under provisions of Section 205 of the 1962 Flood Control Act. Figure 1 is an example of a flood damage prevention measure. The River and Harbor Act of 1970 authorized a program to investigate and undertake measures in the interests of water and environmental quality, recreation, and flood control for the Cuyahoga River Basin. Its purpose is to restore the Cuyahoga River and its tributaries.

Runoff from the upper Cuyahoga River basin is modified by four reservoirs. These reservoirs, shown on plate 1, serve dual purposes: domestic and industrial water supply and flood control. They have been partially financed with Federal funds. The four reservoirs are described below:

(a) Mogadore Reservoir - controls 12 square miles of the head waters of Little Cuyahoga River and was constructed by the Works Project Administration and the City of Akron. The Federal share of total costs was \$900,000. The reservoir supplies raw water to industries in Akron via the channel of the Little Cuyahoga River. (See figure 2).

(b) East Branch Reservoir - is located north of Burton on the Cuyahoga River and regulates river flow to Lake Rockwell Reservoir, the principal water supply reservoir of the City of Akron. The federal share of total costs was \$258,000. The reservoir impounds about 4,600 acre-feet of water and subtends a drainage area of about 18 square miles.

(c) Lake Rockwell Reservoir - is located on the Cuyahoga River about two miles northeast of Kent and was constructed by

PLATE I

the City of Akron for water supply. It controls about 205 square miles of drainage area and has a considerable modifying effect on floods in the upper basin.

(d) LaDue Reservoir - Is located just north of Hiram Rapids and controls about 30 square miles of drainage area. This reservoir was also constructed by the City of Akron for water supply. (See figure 3).

POSSIBLE FLOOD HEIGHTS - Flood levels that would be reached by the Intermediate Regional and Standard Project Floods are shown on table 1. The table compares these flood crests with the January 1959 flood at selected sites along the Cuyahoga River. The water surface profile for the January 1959 flood, the Intermediate Regional Flood, and the Standard Project Flood are shown on plates 8 through 10.

VELOCITIES OF WATER - Estimated average channel velocities on the Cuyahoga River during a major flood occurrence such as the January 1959 flood vary from approximately two to five feet per second in the mildly sloping sections of the river to approximately 14 feet per second in the narrow, steep sloped section in Cuyahoga Falls. Velocities in the overbank areas average 1.5 feet per second. Velocities greater than 3 feet per second combined with flow depths of 3 feet or greater are generally considered hazardous.

HAZARDOUS CONDITIONS - Past floods have caused numerous hazards to local residents. Since many of the past floods have occurred in late winter or early spring, residents may suffer illness and discomfort from lack of heat for a number of days if basement flooding extinguishes furnace fires. In a flood, health problems frequently develop when septic tanks and municipal sewage treatment facilities are taxed beyond their capabilities. Flood waters overtop roads and cause hazardous driving conditions. The amount of damage caused by any flood depends upon the type and extent of development, how much area is flooded, the depth of flooding, the duration of flooding, and the velocity of flow.

GENERAL CONDITIONS AND PAST FLOODS

GENERAL - This section of the report is a history of past floods on the Cuyahoga River from Akron to the Summit-Portage County Line. The study area extends upstream approximately 12 miles from the Akron-Peninsula Road bridge.

THE STREAM AND ITS VALLEY - The Cuyahoga River drains a "U" shaped basin approximately 809 square miles in northeastern Ohio. The basin shown on plate 1 includes parts of Cuyahoga, Geauga, Medina, Portage, Stark and Summit Counties. The river rises about ten miles northeast of Burton, Geauga County, and flows in a southerly direction to near the village of Hiram Rapids, then southwesterly and westerly, passing through Mantua, Kent, and Cuyahoga Falls to its the confluence with the Little Cuyahoga River at Akron, thence northerly to Lake Erie at Cleveland. The total drainage area upstream of the U.S.G.S. gage at Old Portage is 404 square miles, or about 50% of the total Cuyahoga River drainage area. The main tributaries of the river are: Big, Mill, Tinkers, Yellow, Brandywine, and Chippewa Creeks, Mud Brook, Furnace Run, Little Cuyahoga River, Breakneck Creek (Congress Lake Outlet) and West Branch Cuyahoga River.

The watershed consists of rolling hills except for the gently sloping area about three miles wide bordering Lake Erie. The Cuyahoga River rises at about elevation 1,300 feet above mean sea level and discharges into Lake Erie at about elevation 570.0. Upstream of Cuyahoga Falls, the Cuyahoga River cuts through glacial drift and is relatively flat with a fall of about four feet per mile. At Cuyahoga Falls the river cuts through Pennsylvania sandstone and drops 220 feet in 1.5 miles. In the lower northward course, the river flows in a pre-glacial valley with a fall of about five feet per mile. In the reach between the mouth of Tinkers Creek and the head of navigation in Cleveland, the channel falls 25 feet in 10 miles. Most of the residential, commercial, and industrial development in the study area is located on ground lying above the flood plain. Various channel conditions in the study area are shown on figures 4 through 8. Table 2 shows various drainage areas within the Cuyahoga River basin.

STREAM GAGING RECORDS - Presently there are eight gaging stations in the Cuyahoga River basin maintained by the U.S. Geological Survey. The Cuyahoga River gage at Old Portage is the only one in the reach covered by this report. The Old Portage gage is located just upstream of the Akron-Peninsula Road bridge about four miles northwest of Akron. The total drainage area upstream of the gage site is 404 square miles. The first record of stages and discharges on Cuyahoga River at Old Portage began in September 1921. Annual reports published by the United States Geological Survey furnish the average daily discharges in cubic feet per second, the maximum and minimum instantaneous discharges, and the maximum and minimum water stages. An annual publication "Water Resources for Ohio, Part I" is available from the U.S. Geological Survey office in Columbus, Ohio. In recent years, several of the continuous water-stage recorders that produce a graphic representation of the rise and fall of the water surface with respect to time have been replaced by digital-type recorders. A digital-type recorder punches onto a paper tape the stage at a selected time interval permitting the direct computerization of stream flow data. The time interval at which the stage is punched onto the tape is selected such that a stage hydrograph (See Glossary) can be adequately defined. The U.S. Geological Survey also maintains staff gages. A staff gage, a graduated scale anchored vertically on the stream bank, provides a visual determination of the water surface at any given time.

West Branch Cuyahoga River junction	88.6	41.4

SETTLEMENT

CITY OF AKRON - General Simon Perkins, "Father of Akron," came from Connecticut to explore the lands of the Western Reserve. In 1780 he settled in Warren, Ohio, and became an extensive land owner. In 1825, hearing a canal was to be built, he founded the town of Akron. The new town was largely in the hands of his son, Colonel Simon Perkins. After the Ohio Canal was completed in 1827, Akron became an important manufacturing center due to the availability of transportation on the canal. When Summit County was created in 1840, Akron was selected as its county seat. Early industry in Akron included stoneware, pottery plants, and cereal mills. The rubber industry transformed Akron into a booming industrial city in 1900. Today Akron is not only the world's rubber manufacturing center, but it also is one of the major centers of the trucking industry. Other areas of employment include plastics, missile, and aerospace. In 1970 the population of Akron was greater than 270,000.

CITY OF CUYAHOGA FALLS - Originally the land in Cuyahoga Falls had two owners, Joshua Stow and Roger Newberry of Connecticut. In 1804 a company of emigrants started from Middletown, Connecticut for Ohio after making arrangements with Joshua Stow for settlement upon his land. William Wetmore was among those that came. Cuyahoga Falls was first called Manchester. When it was discovered that there were several Manchesters in Ohio, it was decided to name the settlement Cuyahoga Falls. Located on the Cuyahoga River at a point where the river plunges downward 240 feet through a gorge, Cuyahoga Falls was always blessed with an abundance of water power. In 1825 William Wetmore built a dam. Using the power from this dam, a mill was opened for lumber, grain, and linseed oil and established the first major industry in Cuyahoga Falls. By 1837 three dams were converting the force of the Cuyahoga River into power, and Cuyahoga Falls became a promising manufacturing center in Northern Ohio. In April 1851 the Township of Cuyahoga Falls was chartered. The town was re-incorporated as a village of 1868. In 1920 Cuyahoga Falls became a city. Today's industries include rubber, food and dairy products, furniture, wood products and plastics.

VILLAGE OF SILVER LAKE - Originally the Silver Lake area was part of the Western Reserve. In 1804 William Wetmore came to Silver Lake from Connecticut as a real estate agent for Joshua Stow, a purchaser of the township. Before he and his family founded the first white settlement, 500 Seneca Indians were already living there. Silver Lake Village was founded by William R. Lodge in 1917. A charter-type government was adopted in 1926. At one time Silver Lake was one of the leading amusement resorts in Northern Ohio. Its crystal water and natural setting was popular with thousands of people.

CITY OF STOW - Stow Township, originally a part of the Western Reserve, was sold by the Connecticut Land Company to Joshua Stow of Middletown, Connecticut. The first settler was William Walker, a Virginian, who built a home in the northeastern part of the township of 1802. Stow was founded by Joshua Stow and William Wetmore in 1804. Originally attached to Hudson Township for governmental purposes, Stow became a separate political entity in 1808. Part of the city of Cuyahoga Falls was originally in Stow Township.

VILLAGE OF MUNROE FALLS - In March 1836 a wealthy merchant from Boston Massachusetts, Edmund Munroe, founded the town of Munroe Falls. In 1837 the Munroe Falls Manufacturing Company was chartered to manufacture silk, wool, cotton, paper, and flour. Today Munroe Falls has a population of approximately 3,800.

POPULATION - Figure 9 illustrates the population trends for the individual communities in the study area. Since 1950 the population in the study area has increased 25 percent.

DEVELOPMENT IN FLOOD PLAIN - The location of the study area relative to the Cuyahoga River basin is shown on the basin map on plate 1. Although the study area is relatively undeveloped at the present time, population trends indicate that the area will become more developed in the future largely because of the expansion of the Akron metropolitan area. There are several commercial buildings located near the channel in Cuyahoga Falls. It is imperative that flood plain regulations be adopted now so that future development will not be on lands that have been flooded in the past or may flood in the future.

FIGURE 9

EXISTING REGULATIONS - There are no flood plain regulations in the study area. However, flood plain regulations could control development within the flood plain while making the most effective use of land with respect to flood risk. Such regulations may be made possible by counties, municipalities, and townships under their regular zoning and building code statutes. Samples of flood plain regulations passed in communities throughout the country are available at the Buffalo District office.

This report provides local governments with information on which to base their regulations.

In the State of Ohio, the power to adopt and enforce zoning regulations is delegated to political subdivisions. The enabling statutes are sections 303.02, 519.02 and 713.07 of the revised code. The General Assembly of the State of Ohio has passed an amendment to House Bill No. 314 that states all department and agencies of the State shall notify and furnish information to the Division of Water on State facilities which may be affected by flooding. This information is required in order to avoid the uneconomical, hazardous, or unnecessary use of flood plains in connection with State facilities. The amendment further reads that where economically feasible, departments and agencies of the State and political subdivisions responsible for existing publicly owned facilities shall apply flood proofing measures in order to reduce potential flood damage. Under Executive Order 11296, the Federal Government has similar restrictions in that all executive agencies directly responsible for the construction of Federal facilities shall evaluate flood hazards when planning the location of new facilities. In addition, this order requires that executive agencies responsible for the administration of Federal grant, loan or mortgage insurance programs shall evaluate flood hazards in order to minimize potential flood damage and the need for future Federal expenditures for flood protection and flood disaster relief.

FLOOD WARNING AND FORECASTING SERVICES - The study area is well within the effective range of the Weather Surveillance Radar which is operated continuously by the National Weather Service at the Cleveland Airport and the Akron-Canton Airport. This equipment provides for the early detection and plotting of heavy precipitation and makes possible immediate radio and television broadcasts of information concerning the predicted path and amount of rainfall from the storm.

BRIDGES - There are 13 highway bridges, one foot bridge, and one railroad bridge in the reach covered by this study. Table 3 lists pertinent data for these structures and shows the relationship of the Intermediate Regional Flood and the Standard Project Flood to the January 1959 flood.

Water surface profiles shown on plates 8 through 10 should be helpful to local officials in any future construction of new bridges or alterations of existing bridges. At any new bridges there should be sufficient clearance for drift and debris which usually accompany high water. On figures 10 through 13 are photographs of some of the bridges.

DAMS - There are 4 dams on the Cuyahoga River in the study area. Pertinent data on these dams are shown on table 4. Figures 14 and 15 show two of these structures.

OBSTRUCTIONS TO FLOOD FLOWS - Inadequate bridge areas, abandoned dams, encroachments, and fills are some of the obstructions to flood flows. Other serious obstructions are bends in the stream, irregularity of channel section, and heavy brush, weeds, and large trees growing on the channel banks and extending into the stream. Figures 16 through 19 show obstructions which tend to reduce floodway capacity and increase river stages.

To keep obstructions to flows at a minimum, each community should establish maintenance programs for streams within their area. For example, highway crews during slack periods could remove fallen trees, shoals, and debris that may have collected in the channel. A concentrated effort should be made by the people not to throw refuse or other matter into the streams. The local government should establish a floodway, a strip of land on either side of the river that is kept free of obstructions to flows. Flood flows have come in the past and they will come again. A floodway provides extra room when high water comes.

FLOOD SITUATION

FLOOD STAGES AND DISCHARGES - Table 5 lists flood crests and peak discharges for the known floods exceeding bankfull stage of 9.0 feet at the Old Portage gage. (See figure 20) A discharge of approximately 3,500 cfs will produce a stage of 9.0 feet at the gage.

Plate 2 shows known crest stages and years of occurrence of floods since 1913 which have exceeded the bankfull stage of 9.0 feet at the gage.

MAY 1971

DURATION AND RATE OF RISE - Plate 3 shows the stage hydrograph of the January 1959 flood at the U.S.G.S. gaging station on the Cuyahoga River at Old Portage. At the gage site during this flood the river rose to its crest in 26 hours at an average rate of rise of 0.4 foot per hour with a maximum rate of 1 foot in an hour and remained above bankfull (flood) stage for 69 hours.

VELOCITIES - During the January 1959 flood the average channel velocity was approximately two to five feet per second in the mildly sloped reaches. Overbank velocities ranged up to 1.5 feet per second. During a Standard Project Flood, velocities in the channel and overbank would be larger.

FLOODED AREAS, FLOOD PROFILES AND CROSS SECTIONS - Plates 5 through 7 show the approximate areas along the Cuyahoga River that would be inundated by the Intermediate Regional Flood and the Standard Project Flood. The approximate flood elevations of these floods are shown on plates 8 through 10. Typical valley cross sections in the study area are shown on plates 11 through 13.

FLOOD DESCRIPTIONS

Descriptions of known large floods that have occurred in the study area are based upon field investigations, historical records and newspaper accounts. The greatest flood of historical record occurred in March 1913. A condensation of available information on these flood occurrences is given in the following paragraphs. This information is presented as an example of the type and extent of flood problems which have already occurred and an indication of possible future flood problems.

23-26 MARCH 1913 - The storm which caused the greatest flood of historical record in the Cuyahoga River basin developed from the stagnation of a tropical marine air mass from the Gulf of Mexico against a cold air mass from Canada. Heavy rains occurred during the periods 13-15 and 20-21 March. These rains were only preliminary to a severe storm which developed during the period of 23-26 March. This storm extended from Texas to Lake Erie with its center over Bellefontaine, Ohio, 125 miles southwest of the Cuyahoga basin. Two low-pressure centers continued to form a long trough of low pressure which caused excessive rainfall in Ohio and neighboring states for about 60 hours. A record total of 11.16 inches of rainfall fell in Bellefontaine in 92 hours. Along the northeast edge of the storm the Cuyahoga basin received an average of 9.65 inches of rainfall in a 96-hour period. On 23 March 1.85 inches fell; on 24 March 4.75 inches fell; on 25 March 1.89 inches fell; on 26 March 1.16 inches fell. Because of four days of rain, the Cuyahoga River overtopped its banks and brought death and disaster to the valley. Big Reservoir in the Portage Lakes district gave way with millions of gallons of water pouring down the Ohio Canal. The Cuyahoga River was transformed into a rage sweeping everything before it. The flood crest at the Old Portage gate was elevation 752.1 (U.S.C. & G.S. datum).

25-26 JANUARY 1952 - Heavy rain occurred on 25-26 January 1952 over most of Ohio and caused many rivers to go on a rampage. At the Akron-Canton Airport Weather Station, 2.00 inches of rain fell in a 30-hour period over these two days. The maximum rainfall was 0.59 inch in a 3-hour period on 26 January. The severe storm on the 25th and 26th gave record breaking 24-hour precipitation measurements in many areas of Ohio. Some residents were forced to evacuate their homes. High water overtopped a culvert at North Moreland Boulevard and Vancouver Avenue in Cuyahoga Falls and washed away a section of road. Water reached as high as 18 inches over some streets. Some homes had 3 feet of water in their basements.

20-21 JANUARY 1959 - A storm developed from a large mass of cold air over northwestern Canada, a flow of warmer air from the southwest and the associated frontal system. Heavy rains began when the moisture-laden air from the south and the cold front converged. The storm was centered approximately 150 miles southwest of the Cuyahoga River basin. High water caused by two days of rain on 20-21 January 1959 inflicted damage in not only parts of Summit County but throughout the State of Ohio. More rain than usually falls in the whole month of January was dumped on the Akron area on these two days causing widespread damage to homes and highways. Some families were forced to evacuate their homes by boat. Mayor Emmett R. Wolfe of Cuyahoga Falls brought in off-duty firemen to help rescue stranded homeowners and to turn off utilities in flooded basements. During January 1959 temperatures were several degrees below normal. When the temperatures reached -5° on the 18th the ground became frozen. At the Akron Sewage Works 2.86 inches of rain fell during a 30-hour period on 20-21 January. In a 3-hour period on 21 January 0.82 inch of rain fell. Although total rainfall for the storm was not excessive, intensities were high and runoff was increased by the frozen ground and the 6-inch snow cover on the basin. Following the rainfall, there was a warming trend which contributed snow melt. Rainfall averaged 2.34 inches over the entire basin; runoff from rainfall

and snow melt averaged 2.94 inches. Three of the five Cuyahoga Falls' water pumping stations were surrounded by swirling water. The Cuyahoga River swelled 700 feet beyond its banks at the Waterworks Park and surrounded three picnic shelter houses. The swollen river carried away 20 picnic tables from the park. At the Old Portage gage the January 1959 flood reached elevation 751.6, U.S.C. & G.S. datum, which is approximately 2.5 feet above bankfull stage. Flooding conditions in January 1959 are shown on figures 21 and 22.

This concludes the "General Conditions and Past Floods" section of this report. What can be done to prevent and/or reduce future flood damages? FLOOD PLAIN MANAGEMENT provides the solution! Wise flood plain management can control the use of the flood plain as a means of reducing damage caused by future flooding.

By using the flooded area maps, profiles and cross sections contained in this report is a guide, limited urban development can be allowed in the flood plain depending on the frequency of flooding. The elevations shown on the profiles should be used to determine flood heights because they are more accurate than the flooded outlines. Units of low damage construction should be stressed during future development in areas which are susceptible to frequent flooding. If it is uneconomical to elevate these lands, a means of flood proofing the structures should be given careful consideration.

As soon as possible, local governments should develop and enforce flood plain regulations based on the information contained in this report. This report provides local governments with the necessary tools to control the extent and type of development which would be allowed to take place within the flood plain. Regulation of the flood plain can usually be carried out most effectively by a combination of the several regulatory methods ... zoning ordinances, subdivision regulations and building codes. Local governments can also police and maintain the floodway so as to insure against the overgrowth of brush, weeds, debris and large trees which obstruct flood flows. All of these factors result in increased river stages. The U. S. Army Corps

of Engineers has prepared and is distributing to state, county and local governments for public dissemination two pamphlets, "Guidelines for Reducing Flood Damages" and "Introduction to Flood Proofing." The combination of data presented in this report and in the pamphlets will provide general guidelines for flood damage reduction in future development within the Cuyahoga River flood plain. Figure 23 lists the corrective and preventive measures described in the above mentioned pamphlets. The U. S. Army Corps of Engineers will distribute to State, county and local governments other helpful pamphlets as well as additions to existing pamphlets when they are developed. Figures 24 through 27 are examples of wise flood plain use.

FUTURE FLOODS

In order to determine future floods, it is desirable to study past floods on other streams in the same general region. Table 6 lists the maximum known floods at various U.S.G.S. gaging stations.

This section of the report discusses two future floods: the Intermediate Regional Flood and the Standard Project Flood on the Cuyahoga River.

The Standard Project Flood is a severe flood of infrequent occurrence. It is possible, but unlikely, that a flood of greater magnitude could occur. The Standard Project Flood concept developed by the U. S. Army Corps of Engineers provides an indication of the upper limit of flooding in a particular area and is used to compare floods in different locations throughout the United States.

The Intermediate Regional Flood may reasonably be expected to occur more frequently than the Standard Project Flood. To avoid possible damage from floods of Intermediate Regional or Standard Project magnitude, flood plains should not be developed without consideration to possible future flood elevations, the risks involved, and possible alternatives.

TABLE 6

MAXIMUM KNOWN FLOOD DISCHARGES AT U.S.G.S. GAGING STATIONS IN THE REGION OF CUYAHOGA RIVER, OHIO

Stream	Location Ohio	Period of: Record : (years)	Drainage : Area : (sq. mi.)	Date	Peak Discharge of Record: Amount (cfs) : Date	Estimated Recurrence Interval (years)
Cuyahoga River : Independence (1)		41	707	:22 Jan. 1959:	21,400 (3): 29.7	100
Cuyahoga River : Old Portage		46	404	:21 Jan. 1959:	6,500 : 16.1	200
Sandusky River : Fremont (2)		44	1,251	:10 Feb. 1959:	28,000 (4): 22.4	10
Huron River : Milan		20	371	:5 July 1969:	49,600 : 131.8	200
Vermilion River : Vermilion		18	262	:6 July 1969:	40,800 : 155.7	100
Black River : Elyria		25	396	:6 July 1969:	51,700 : 130.6	greater than 200
Rocky River : Berea		37	267	:22 Jan. 1959:	21,400 : 80.1	70
Chagrin River : Willoughby		40	246	:22 Mar. 1948:	28,000 : 113.8	60
Grand River : Madison		45	581	:22 Jan. 1959:	21,100 : 36.3	100
Ashtabula River : Ashtabula		41	121	:22 Jan. 1959:	11,600 : 95.9	50
Conneaut Creek : Conneaut		34	175	:22 Jan. 1959:	17,000 : 97.1	60

(1) The estimated peak discharge of the maximum flood of record was 30,000 cfs for the 1913 flood. It has a recurrence interval on the order of once in 200 years.

(2) The estimated peak discharge of the maximum flood of record was 63,500 cfs for the 1913 flood. It has an exceedance interval of about 200 years based on a discharge-frequency basis and about 200 years on a stage frequency basis.

(3) Estimated by Corps of Engineers.

(4) Estimated by U.S.G.S.

DETERMINATION OF INTERMEDIATE REGIONAL FLOOD

The Intermediate Regional Flood is defined as a flood having a recurrence interval of once in 100 years at a designated location. However, this flood may occur in any one year or in consecutive years. A statistical analysis of stream flow records available for the basin under study is often used to determine a frequency of occurrence, but limitations in such records usually require analysis of rainfall and runoff characteristics in the "general region" of the area. Although the Intermediate Regional Flood represents a major flood, it is much less severe than the Standard Project Flood.

Results of the studies indicate that the Intermediate Regional Flood on Cuyahoga River at the Old Portage gaging station would have a peak discharge of 5,820 cubic feet per second.

DETERMINATION OF STANDARD PROJECT FLOOD

Only in rare instances has a specific stream experienced the largest flood than can be expected to occur. It is a commonly accepted fact that sooner or later a larger flood can and probably will surpass the maximum known flood on a given stream. The Corps of Engineers, in cooperation with the National Weather Service, has made broad and comprehensive studies and investigations based on the records of past storms and floods and has evolved generalized procedures for estimating the flood potential of streams. These procedures have been used in determining the Standard Project Flood. The Standard Project Flood is defined as the flood that can be expected from the most severe combination of meteorological and hydrological conditions that is considered reasonably characteristic of the geographical region involved. Although the Standard Project Flood has only a rare chance of occurrence, it is not the most severe flood that could occur. The Standard Project Storm rainfall used for the Cuyahoga River at Old Portage gage amounts to 0.32 inch for 24 hours, 1.73 inches for 48 hours, 8.44 inches for 72 hours, and a total of 8.99 inches in 96 hours. Rainfall of this magnitude has recently been recorded in the region. In July 1969 in

Wooster, Ohio 9.37 inches of rain fell in 24 hours, and a total of 10.69 inches fell in 96 hours. The peak discharge of the Standard Project Flood on Cuyahoga River at the U.S.G.S. gaging station at Old Portage is 41,100 cfs. The Standard Project Flood discharge was based on the assumption that there would be no storage in the reservoirs in the upper basin of the Cuyahoga River.

FREQUENCY - It is not practical to assign a frequency to a Standard Project Flood. Generally its recurrence interval would be more rare than once in 500 years. However, the flood could occur during any year.

POSSIBLE LARGER FLOODS - Floods larger than the Standard Project Flood are possible. However, the combination of factors that would be necessary to produce such floods seldom occur.

HAZARDS OF GREAT FLOODS

AREAS FLOODED AND HEIGHTS OF FLOODING - The areas along the Cuyahoga River inundated by the Standard Project and Intermediate Regional Floods are shown on plates 5 and 7. Depths of flow for the Standard Project Flood, the Intermediate Regional Flood, and the January 1959 flood can be estimated from the valley sections which are shown on plates 11 through 13.

The January 1959, the Intermediate Regional and the Standard Project flood profiles were computed by using stream characteristics for selected reaches as determined from observed flood profiles, topographic maps and valley cross sections. The overflow areas shown on plates 5 through 7 and the water surface profiles shown on plates 8 through 10 have been determined with an accuracy consistent with the purpose of this study and the accuracy of the available basic data. The water surface profiles depend to a great extent upon the degree of destruction or clogging of various bridges during the flood occurrence. Because it is impossible to forecast these events, it was assumed that all bridge structures would stand and that no clogging would occur.

In the study area the Standard Project Flood for the Cuyahoga River averages approximately 12 to 15 feet higher than the January 1959 flood stage.

Upstream of the confluence of the Little Cuyahoga River, the Intermediate Regional Flood profile averages approximately one foot higher than the 1959 flood stage.

The approximate heights of the Standard Project Flood, the Intermediate Regional Flood, and the January 1959 flood at selected sites are shown in figures 29 through 35.

Figure 29 - Arrows indicate the heights of the Standard Project, Intermediate Regional, and the January 1959 floods at the upstream face of the Akron-Peninsula Road bridge, stream mile 40.25.

Possible future flood heights
Photograph was taken in December 1970.

VELOCITIES, RATES OF RISE AND DURATION OF FLOODING - Table 7 lists the average velocities that would occur in the channel and overbank areas during the Intermediate Regional and Standard Project Floods.

Rates of rise are dependent upon the development, rainfall intensity, slope of the basin and loss rate of rainfall. They can also depend upon the condition of the channel and amount of debris in the channel at the time of the storm. The duration of a flood above bankfull stage is dependent upon the duration of the storm and on the assumption that the storm was caused by rainfall and does not include prolonged runoff from snow melt and high stages caused by ice jams, etc. Table 8 lists the total rise from low water to the crest, the maximum rate of rise, and the duration above bankfull stage of the Intermediate Regional and Standard Project Floods for the Cuyahoga River.

TABLE 7
AVERAGE MAXIMUM VELOCITIES

Location	Stream Mile	Flood	*Maximum Velocities	
			channel (ft per sec)	overbank (ft per sec)
U.S.G.S. gage at Old Portage	40.27	Intermediate Regional	5.9	1.1
		Standard Project	9.7	3.6
Valley Section B	41.80	Intermediate Regional	3.7	0.8
		Standard Project	3.8	1.3
Valley Section C	43.77	Intermediate Regional	9.1	-
		Standard Project	16.8	5.3
Valley Section D	47.61	Intermediate Regional	2.5	0.3
		Standard Project	4.8	1.4
Valley Section F	51.87	Intermediate Regional	2.3	0.5
		Standard Project	5.0	1.6

*Average maximum velocity for selected location. Velocities could be greater in isolated areas, especially in overbank section. High channel and overbank velocities, in combination with deep, fairly long-duration flooding, would create a hazardous situation in the flood plain. When velocity (in feet per second) times depth (in feet) is greater than nine, hazardous conditions prevail.

TABLE 8
RATES OF RISE AND DURATIONS OF FLOODING
AT U.S.G.S. GAGE AT OLD PORTAGE
STREAM MILE 40.27

Flood	: Time of: : rise : (hrs)	: Maximum rate : of rise : (ft/hr)	: Duration above : bankfull stage : (hrs)
Intermediate Regional	: 30	: 0.7	: 58
Standard Project	: 53	: 0.6	: 135

These rates of rise should give adequate warning that a flood is coming. However, a clogged bridge or an ice jam could act as a dam and cause water to back up and form a pond. When sufficient head accumulates in the pond to break the jam, a surge of water would flow downstream causing an almost instantaneous rate of rise.

GLOSSARY OF TERMS

Discharge. The quantity of flow in a stream at any given time, usually measured in cubic feet per second (cfs).

Flood. An overflow of lands not normally covered by water and that are used or usable by man. Floods have two essential characteristics: The inundation of land is temporary; and the land is adjacent to and inundated by overflow from a river or stream or an ocean, lake, or other body of standing water.

Normally a "flood" is considered as any temporary rise in stream flow or stage, but not the ponding of surface water, that results in significant adverse effects in the vicinity. Adverse effects may include damages from overflow of land areas, temporary backwater effects in sewers and local drainage channels, creation of unsanitary conditions or other unfavorable situations by deposition of materials in stream channels during flood recessions, rise of ground water coincident with increased stream flow, and other problems.

Flood Crest. The maximum stage or elevation reached by the waters of a flood at a given location.

Flood Peak. The maximum instantaneous discharge of a flood at a given location. It usually occurs at or near the time of the flood crest.

Flood Plain. The relatively flat area or low lands adjoining the channel of a river, stream or watercourse or ocean, lake, or other body of standing water, which has been or may be covered by flood water.

Flood Profile. A graph showing the relationship of water surface elevation to location, the latter generally expressed as distance above mouth, for a stream of water flowing in an open channel. It is generally drawn to show surface elevation for the crest of a specific flood, but may be prepared for conditions at a given time or stage.

Flood Stage. The stage or elevation at which overflow of the natural banks of a stream or body of water begins in the reach or area in which the elevation is measured.

Head Loss. The effect of obstructions, such as narrow bridge openings or buildings that limit the area through which water must flow, raising the surface of the water upstream from the obstruction.

Hydrograph. A curve denoting the discharge or stage of flow over a period of time.

Intermediate Regional Flood. A flood having an average frequency of occurrence in the order of once in 100 years although the flood may occur in any year. It is based on statistical analyses of streamflow records available for the watershed and analyses of rainfall and runoff characteristics in the "general region of the watershed."

Left Bank. The bank on the left side of a river, stream, or watercourse, looking downstream.

Low Steel (or Underclearance). See "underclearance."

Right Bank. The bank on the right side of a river, stream, or watercourse, looking downstream.

Standard Project Flood. The flood that may be expected from the most severe combination of meteorological and hydrological conditions that is considered reasonably characteristic of the geographical area in which the drainage basin is located, excluding extremely rare combinations. Peak discharges for these floods are generally about 40% to 60% of the Probable Maximum Floods for the same basins. Such floods, as used by the Corps of Engineers, are intended as practicable expressions of the degree of protection that should be sought in the design of flood control works, the failure of which might be disastrous.

Underclearance. The lowest point of a bridge or other structure over or across a river, stream, or watercourse that limits the opening through which water flows. This is referred to as "low steel" in some regions.

AUTHORITY, ACKNOWLEDGMENTS AND INTERPRETATION OF DATA

PUBLIC LAW - This report has been prepared in accordance with the authority granted by Section 206 of the Flood Control Act of 1960 (PL 86-465), as amended.

* * *

ACKNOWLEDGMENTS - The assistance and cooperation of the United States Geological Survey, National Weather Service, Ohio Department of Natural Resources, Tri-County Regional Planning Commission, various local governmental agencies in the study area, and private citizens in providing useful data are appreciated.

* * *

This report presents the local flood situation caused by the Cuyahoga River from Akron to the Summit-Portage County line. The U. S. Army Engineer District, Buffalo, will provide interpretation and limited technical assistance in the application of the data contained in this report, particularly as to its use in developing effective flood plain regulations. Requests should be coordinated through the Ohio Department of Natural Resources, Division of Water. After local authorities have selected the flood magnitude or frequency to be used as the basis for regulation, the Corps of Engineers can assist in the selection of floodway limits by providing information on the effects of various widths of floodway on the profile of the selected flood.
