ABSTRACT

The temperature sensitive (ts) mutant Ag(293) of herpes simplex type 2 virus (HSV-2) was employed in tests to detect chemical interactions with the virus causing increased transformation of target cells. Mouse 3T3 cells were monitored for morphological transformation. Hydrazine and 1,2-dimethylhydrazine caused an enhancement of viral transformation of between three to four fold, confirming earlier findings using ultraviolet light inactivated wild type virus.

Norharman (9H-pyrido[3,4-b]indole), a component of tobacco tars, caused a nearly three-fold enhancement of transformation. Xylene and toluene were not found to enhance viral transformation. Experiments involving host-mediated activation of the test chemicals were unsuccessful because of low target cell recovery due to inhibition of the target 3T3 cells.

NOTICE OF TRANSMITTAL TO DTIC

This technical report has been reviewed and is
approved for public release IAW AFR 190-12.
Distribution is unlimited.

MATTHEW J. KERPEN
Chief, Technical Information Division

RESEARCH OBJECTIVES:

a. Determine if HSV-2-mediated transformation is enhanced following metabolic activation of the following chemicals:

dimethylnitrosamine (N-nitrosodimethylamine) (a known procarcinogen)
hydrazine
monomethylhydrazine
1,2-dimethylhydrazine
1,1-dimethylhydrazine
JP-5
JP-10
RJ-4
RJ-5

b. Determine if HSV-2-mediated transformation is enhanced when cells are simultaneously exposed to virus and the following suspected tumor promoters:

norharman
toluene
xylene

STATUS OF THE RESEARCH EFFORT: ACCOMPLISHMENTS.

A. Refinement of the Transformation Assay.

We previously reported the testing of a series of ts mutants of HSV-2 for transformation activity. The mutant ts Ag(293) was selected as an indicator strain to determine transformation enhancement. The method, as it is presently being used, is shown in Fig. 1. This method avoids some of the pitfalls of the previous method, namely the sometimes erratic appearance of reactivated virus in UV-irradiated preparations.

B. Enhancement of Transformation by Hydrazine and 1,2-dimethylhydrazine Using the Mutant Virus Assay System.

We previously found enhancement of virus transformation by hydrazine (Hz) and symmetrical dimethylhydrazine (SDMH) in assays which employed UV-irradiated virus. The refined assay using the mutant virus had not been tested until this year when these tests were accomplished. (Refer to Table 1, Table 2, Fig. 2 and Fig. 3). These results show that virus interactions with Hz or SDMH (or Hz and SDMH catabolites) and the infected cell lead to greater numbers of transformed cells which grow out to recognizable foci.

C. Enhancement of Transformation by Norharman

Norharman, a compound found in tobacco tars and in tryptophan pyrolysates, was tested for enhancement. In other systems, alone, norharman has not mutagenic activity, but enhances the mutagenicity of several typical mutagens such as benzo [a] pyrene, dimethylaminoazobenzene and 2-acetyl-aminofluorene derivatives. Moreover, aniline and o-toluidine, which alone are non-mutagenic become mutagenic in the presence of norharman. The results of the present study show enhancement of herpes virus transformation in the presence of norharman when the chemical is added before the initiation of virus infection (Table 3, Fig. 4).

D. Lack of Enhancement by Xylene and Toluene.

Under the conditions and at the concentrations tested reagent grade xylene or toluene did not cause enhancement of virus transformation (Table 4, Table 5).

E. Host Mediated Activation of Chemicals.

The host mediated activation system of Hsie, et. al. (Mutation Res. 51: 77-84, 1978) was employed to determine whether prior activation of the chemicals would cause some of the previously negative chemicals to appear as positive virus enhancers. Balb/c mice were injected intraperitoneally with 3T3 cells and the chemical was injected subcutaneously. After two hours the cells were

removed from the peritoneal cavity, counted, plated and infected with virus. After four weeks, with weekly media changes, the cells were examined for the development of transformed foci. A major technical problem was encountered, i.e. the recovery of viable 3T3 cells from the peritoneal cavity. This was a problem even in control animals which received no chemical, so the loss of viability could not simply be ascribed to chemical toxicity. No matter how many cells were inoculated (up to 16×10^6) the recovery was always low. Even in the peritoneal cavity were extensively irrigated the recovery was low. Hence, the results were based upon formation of only limited numbers of clones. In these studies none of the previously negative chemicals showed up as a positive enhancer, but the nature of the technical difficulty prevents any conclusions being drawn, except that the animals caused loss of viability of the 3T3 cells, perhaps by allogeneic inhibition.

PROFESSIONAL PERSONNEL ASSOCIATED WITH THE RESEARCH EFFORT:

1. F. Brent Johnson, Ph.D., principal investigator.
2. Joyce R. Baker, Ph.D., research technician.

INTERACTIONS:

Participation in and presentation of a report at the Review of Air Force Sponsored Basic Research in Environmental Toxicology, 2-3 June 1981, Columbus, Ohio.

NEW DISCOVERIES STEMMING FROM THE RESEARCH EFFORT:

1. Supportive evidence was obtained for the transformation enhancing activity of hydrazine and 1,2-dimethylhydrazine in assays involving the mutant virus.
2. That norharman enhances the transformation potential of herpes simplex type 2 virus.
3. That xylene and toluene were negative in enhancement assays.

ENHANCEMENT ASSAY

Fig. 1. Assay scheme for the determination of chemical enhancement of herpes virus transformation. The "minus" system refers to exposure of the cells to the chemical prior to virus infection. The "plus" system indicates exposure to the chemicals after virus infection. For each concentration of chemical to be tested (from 0 to N number of concentrations) four petri dishes are seeded with 250,000 cells in each dish. Some dishes are set aside as cell controls. The chemical, contained in cell culture medium, is added to the cells for the length of time to be tested. Some cells are removed and plated for survival to determine chemical toxicity. At the end of the chemical exposure time the media are removed, the cell sheets washed with PBS, the virus added and allowed to absorb for one hour then fresh media added to the cultures. In the "plus" system, the chemical is on for 24 hrs., then washed away and the cells renewed with fresh media. At the end of the incubation period the cell sheets are examined for foci of morphologically transformed cells.
