16. Abstract This document presents detailed computer algorithms for programming the Automatic Traffic Advisory and Resolution Service (ATARS). A major feature of this version of the ATARS algorithms is the capability to exchange resolution advisory information via the airborne Resolution Advisory Register (RAR). This provides for coordination of resolution advisories between ATARS and airborne collision avoidance systems and between adjacent ATARS sites in the absence of ground communication lines. The ground based ATARS computers use the surveillance data from the Discrete Address Beacon System (DABS) to provide properly equipped aircraft with traffic advisories and collision resolution advisories. These advisories are discretely delivered to the aircraft via the DABS data link. The ATARS algorithms are presented in two volumes rather than one large document in order to provide the algorithms in a more manageable form. DTIC SEP 14 1981 H

12. MASTER RESOLUTION TASK

The Master Resolution Task utilizes the aircraft pair output data of the ATARS Detect Task to manage encounters and determine resolution advisories. Its functions are:

1. Cause resolution advisories to be issued when two requests for resolution advisories on any three consecutive scans have been generated by the detection logic or issue resolution advisories immediately when the detection logic has determined that a maneuvering aircraft is a threat.
2. Select the appropriate positive or negative resolution advisories for the pair using the Resolution Advisories Evaluation Routine (RAER). If existing resolution advisories prevent the selection of resolution advisories for this pair, attempt resolution later in the scan.
3. Recalculate resolution advisories if the advisories selected on the previous scan are incompatible with advisories selected by another source (a remote ATARS site or BCAS). Incompatibility could occur if two or more sources are selecting advisories on the same scan, and the sources do not have the capability of communicating with each other.
4. Calculate double dimension resolution advisories if either maneuvering aircraft's turn status changes so as to be counterproductive to the horizontal resolution advisory selected. Recalculate resolution advisories if the relative vertical velocity of the pair changes so as to indicate that the selected vertical resolution advisories are ineffective. Check for these conditions for two scans after resolution advisories are initially chosen or modified.
5. Select a resolution advisory for a controlled aircraft in conflict with an uncontrolled aircraft when the detection logic determines that the resolution advisory to the uncontrolled aircraft is not providing sufficient separation. Select a resolution advisory for a controlled aircraft whenever there is a multi-aircraft conflict regardless of the detection logic's determination of the necessity for a resolution advisory to the controlled aircraft.

6. Monitor the change in the resolution dimension miss distance and transition resolution advisories between positive and negative as the projected separation of the encounter changes.
7. Monitor the response of aircraft to ATARS positive single dimension resolution advisories and, if necessary, issue additional resolution advisories in the event of apparent non-response, as evidenced by a diminishing miss distance in the resolution dimension.

12.1 Overview

Table 12-1 is a high-level description of the major functions performed by the Master Resolution Task. The basic strategy of the task is to select resolution advisories for each conflict pair based on the status of all aircraft in a conflict cluster (as given in the Conflict Table). These advisories are recorded in the Pair Record and the effective resolution advisory is placed in each aircraft's Conflict Table Entry.

The resolution advisories in the Pair Record may be thought of as representing the desired resolution advisories for this pair. All of the desired resolution advisories for an aircraft are examined and the most severe resolution advisory in each dimension becomes the effective resolution advisory in that dimension in the Conflict Table Entry. As pairs go in and out of conflict, the effective resolution advisory for an aircraft may change severity (positive/negative) and/or dimension (vertical/horizontal).

Because the resolution logic interacts extensively with the Conflict Table and Pair Records, these data structures are discussed next. They are defined in pseudocode Section 3.5.

12.2 Conflict Table and Pair Record Data Structures

There are two types of data required by the Master Resolution Task for management of ATARS resolutions:

1. Inherently pairwise information, such as time at which resolution advisories were initiated or miss distance on previous scan
2. Multi-aircraft information concerning the entire cluster of conflicting aircraft

TABLE 12-1

MAJOR FUNCTIONS PERFORMED BY THE
MASTER RESOLUTION TASK

Master Resolution Task

1. Own ATARS site resolution responsibility
 - Other ATARS sites' resolution advisories adequacy test
2. Initial resolution advisory selection
 - Resolution Advisories Evaluation Routine
 - If unable to select advisories, delay resolution
3. Recalculate advisories if previous advisories are incompatible with advisories from another source
 - Resolution Advisories Evaluation Routine
 - If unable to select advisories, delay resolution
4. Recalculate advisories if the conflict geometry has changed detrimentally
 - Resolution Advisories Evaluation Routine
 - If unable to select advisories, continue present advisories
5. Positive/negative resolution advisory transition
 - Resolution Advisories Evaluation Routine
 - If unable to select advisories, continue present advisories
 - Vertical speed limit advisory evaluation

TABLE 12-1
(Concluded)

6. Controlled aircraft resolution advisory
addition in controlled/uncontrolled pair
 - Resolution Advisories Evaluation Routine
 - If unable to select advisories,
continue present advisories
7. Recalculate advisories if aircraft non-response is
detected
 - Resolution Advisories Evaluation Routine
 - If unable to select advisories,
continue present advisories
8. Resolution advisory posting to Pair Record and Conflict
Table Entries

Each aircraft involved in a conflict has a pointer, CTPTR, in its system State Vector pointing to the head of a Conflict Table. The Conflict Table Head consists of the count of the number of aircraft in the cluster, pointers to the head of the next and previous Conflict Tables in the linked list of Conflict Tables, a flag that indicates whether any aircraft in this Conflict Table is in an ATARS seam, a pointer to the list of the Pair Records, and a pointer to the first of the Conflict Table Entries.

The Conflict Table Entries, one for each aircraft in a conflict, make up the body of the Conflict Table. The Conflict Table Entries are linked together to permit easy insertion or deletion of aircraft (although the table could be conceptually regarded as a simple array of Conflict Table Entries). The fields in each Conflict Table Entry are used to record information about the aircraft in relation to the conflict cluster, to record the effective vertical and horizontal resolution advisories (VMAN and HMAN) for each aircraft, and to record the advisories being displayed (VMAND and HMAND) after the most recent scan.

For every aircraft pair declared in conflict, a Pair Record is created and linked into the list of Pair Records for this Conflict Table. The Pair Record contains information on the particular encounter underway, the selected resolution advisories for the pair, pointers to the Conflict Table Entries of the aircraft involved and the identification of the ATARS function controlling the resolution of that pairwise conflict or an indication of BCAS control.

A Pair Record is also created when an aircraft receives a resolution advisory from BCAS or from a non-connected ATARS site. In this case, the identification of the other aircraft is set to a dummy value.

The interplay of the Conflict Table and Pair Records (as discussed in the following sections) permits:

1. The selection of resolution advisories based on the status of the entire conflict cluster under the multi-aircraft rules
2. The management of modifications to resolution advisories due to resolution advisory transitions in severity and dimension

The Pair Records and Conflict Table for a sample three-aircraft conflict are shown in Figure 12-1. Only a portion of each aircraft's State Vector is shown.

Both conflict pairs in the example have one aircraft, AC3, in common. Therefore, all three aircraft are placed in the same Conflict Table, CT1, which is pointed to by each aircraft's State Vector Conflict Table pointer, CTPTR. Each State Vector also points to its respective Conflict Table Entry by the Conflict Table Entry pointer, CTE. Since an aircraft may be in more than one Pair Record at a time, there is no pointer from the State Vector directly to the Pair Records. However, the list of Pair Records associated with this Conflict Table is pointed to from the Conflict Table Head using the pointer PLIST. A particular Pair Record may be pointed to from the Conflict Table Entry. A Pair Record that has a horizontal resolution advisory for an aircraft is pointed to by the ACIDH field in the Conflict Table Entry. Only one Pair Record is pointed to by ACIDH (ACIDV). The field MULTH in the Conflict Table Entry is a count of the number of Pair Records containing a horizontal resolution advisory for an aircraft. A value of MULTH (MULTV) greater than one indicates that more than one conflict pair is contributing to the effective horizontal (vertical) resolution advisory for an aircraft.

In the example shown in Figure 12-1, the first Pair Record records information for the conflict between AC1 and AC3. The selected advisories, turn left (L) and turn right (R), are recorded in the Pair Record and in the Conflict Table Entries. The Conflict Table Entries for AC1 and AC3 point to the first Pair Record, PR1, as containing the horizontal resolution advisories for these two aircraft.

The second conflict involves AC2 and AC3. The selected resolution advisories climb (C) and descend (D) for this pair are recorded in the second Pair Record, PR2, and in the Conflict Table Entries for AC2 and AC3.

The field NCON in the Conflict Table Entries is a count of the number of conflicts in which an aircraft is involved.

12.3 Selection of Resolution Advisories for a Conflict Pair

The Master Resolution Task uses the output of the Detect Task to determine if resolution advisories must be calculated for a pair of aircraft. Master resolution may determine that resolution advisories are not required, that this is the first time

resolution advisories are required or that resolution advisories should be recomputed for the pair. Each of these possibilities is discussed in the following sections.

Before the Master Resolution Task can determine if resolution advisories are required this scan, it must determine if this ATARS site is responsible for the pair. If the RAREQ flag is set in the Encounter List entry, then own site is responsible. However, if the Seam Pair Task has flagged this site as provisionally responsible, then master resolution examines the resolution advisories being given to the DABS aircraft in the pair from other, higher-priority ATARS sites. If those advisories are determined to be adequate to resolve the conflict, then own site is not responsible for the pair. If they are determined not adequate, then own site takes responsibility for the pair.

12.3.1 Initiation of Resolution Advisories

Because ATARS decisions are based on tracked information which is subject to random fluctuations from scan to scan, it is desirable to incorporate logic to reduce false alarms when dealing with resolution advisories. Incorporating a rule which requires the conditions for issuing resolution advisories to be satisfied on two consecutive scans normally could prevent unnecessary resolution advisories because of errors on a single scan. But this rule can also lead to late alarms. If on one scan the calculations require resolution advisories, but on the second scan they do not (because of random errors) when they should, then it would require two additional scans to fully declare the conflict, and a late resolution would occur. To alleviate this problem, a rule is implemented which will issue resolution advisories if the Detect Task requires resolution advisories on any two of three consecutive scans.

This two-out-of-three rule is implemented through the use of a conflict control variable, POSCMD. When a request for resolution advisories is generated for a given pair, a Pair Record is created and POSCMD is initialized. POSCMD is then updated according to the transition logic in Table 12-2. POSCMD is updated on each scan that the Master Resolution Task is called for a conflict pair, until POSCMD reaches a value indicating that resolution advisories should be computed. The maneuvering target threat flag, MTTFLG, indicates an immediate need for resolution advisories. If MTTFLG is set (Section 8), then the normal transition sequence is bypassed and resolution advisories are calculated immediately.

TABLE 12-2
POSCMD TRANSITION LOGIC

<u>PREVIOUS POSCMD¹</u>	<u>NEW VALUE OF POSCMD BASED ON VALUE OF FLAGS FOR CURRENT SCAN</u>		
	<u>MTTFLG Flag</u>		
	<u>Set</u>	<u>Not set</u>	
		<u>CMDFLG Flag</u>	
		<u>Set</u>	<u>Not Set</u>
\$NOTSET ²	\$RANEC	\$ONEHIT	\$NORA
\$ONEHIT	\$RANEC	\$RANEC	\$ONEMIS
\$ONEMIS	\$RANEC	\$RANEC	\$NORA

¹POSCMD takes on additional values after resolution advisories are selected. See Appendix B.

²\$NORA - Conflict detected on only one out of three scans. Resolution advisories are not needed for this pair. The pair may be deleted.

\$NOTSET - Initial value, POSCMD not set.

\$ONEHIT - Conflict detected on one scan. Resolution advisories not yet necessary.

\$ONEMIS - Conflict detected on one scan, no conflict detected on the next scan. Resolution advisories not yet necessary.

\$RANEC - A conflict has been detected on two out of three scans or the immediate need for resolution advisories has been detected. Resolution advisories should be computed for this pair.

The Detect Task determines the need for resolution advisories and sets the CMDFLG and MTFLG accordingly. The Seam Pair Task evaluates the site's resolution responsibility for the pair. When no resolution is performed, Resolution Deletion Task or Conflict Pair Cleanup Task handles the updating of POSCMD. If POSCMD reaches a state indicating no resolution advisory is necessary, the pair is declared to be not in conflict and the Pair Record is deleted (Section 15). The Conflict Table Entries may be deleted if the aircraft are in no other conflicts.

12.3.1.1 Initial Resolution Advisory Selection

When master resolution first determines that resolution advisories should be selected for a pair of aircraft in conflict, it calls the Resolution Advisories Evaluation Routine (RAER) to select the actual advisories. Three parameters are passed to the Resolution Advisories Evaluation Routine from master resolution along with the identification of the subject conflict pair. One parameter indicates whether single or double dimension resolution advisories are desired.

The second parameter indicates that the Master Resolution Task is calling the Resolution Advisories Evaluation Routine. This indicates to RAER that the complete resolution logic should be performed. This is in contrast to when RAER is called by the Conflict Resolution Data Task. These differences are explained in Section 13.

The third parameter is passed indirectly to the Resolution Advisories Evaluation Routine. This is an indication of whether the controlled aircraft is to be maneuvered. A resolution advisory is always selected for an ATARS-equipped uncontrolled aircraft in a conflict pair when it is not in a final approach zone. If either aircraft is an ATARS-equipped controlled aircraft, a resolution advisory is selected for that aircraft only if the PIFR flag in the Pair Record has been set by master resolution.

Master resolution sets the PIFR flag in the Pair Record if the detection logic has indicated that any controlled aircraft in this pair should receive resolution advisories. The detection logic indicates this by setting the IFRFLG.

Master resolution will also set the PIFR flag if the current conflict pair contains an ATARS-equipped controlled aircraft and is part of a multi-aircraft conflict. If an ATARS-equipped aircraft is in a multi-aircraft cluster, it is desirable to

actively maneuver the aircraft in resolving the conflict, rather than counting on two or more other aircraft to resolve the conflict.

12.3.2 Resolution Advisory Change Logic

Subsequent to the first scan that resolution advisories are selected, the severity (positive/negative), resolution dimension (horizontal/vertical) and even the number (single/double dimension) of resolution advisories for a conflict pair may change from scan to scan. The various conditions under which the resolution advisories may change are described in the following sections.

12.3.2.1 Recomputation Because of Incompatible Resolution Advisories

Resolution advisories may be selected for an aircraft pair at one ATARS site at the same time that resolution advisories are being selected for one or both of the aircraft by BCAS or by another non-connected ATARS site. If this situation occurs it is possible for the resolution advisories selected by the two different sources to be incompatible. If the resolution advisories from BCAS or the other ATARS site are accepted by the aircraft before the resolution advisories from the local site are uplinked, then the advisories from the local site will be rejected by the ATARS avionics. This condition will be recognized by the RAR Processing Task, which will delete the advisories in the Pair Record and set the conflict control variable, POSCMD, to indicate that the resolution advisories from this site must be recalculated. The setting of POSCMD will also indicate if single or double dimension resolution advisories were selected by this site.

The first check done by the Master Resolution Task when resolution advisories were given previously is to determine if they must be recomputed because of incompatibility with resolution advisories from other ATARS sites or BCAS. If RAER is called to recompute advisories and it is unable to select new resolution advisories, resolution is delayed.

12.3.2.2 Validation of Resolution Advisories

The horizontal turn status of each maneuvered aircraft and the relative vertical velocity of the aircraft pair are factors in selecting resolution advisories for a conflict pair. To ensure that the turn status of the maneuvered aircraft or the relative

vertical velocity of the pair has not changed in a way detrimental to the selected resolution advisories, a validation of the PSEP modeling assumptions is performed within two scans of selecting single dimension resolution advisories. This logic is referred to as the PSEP model validation logic.

For two scans after horizontal-only resolution advisories are selected, master resolution checks for the turn status of either aircraft changing from its status on the scan in which resolution advisories were selected. If the turn status has changed and the current turn status is detrimental to the selected resolution advisories, then resolution advisories are recalculated. RAER is called and double dimension resolution advisories are requested. Table 12-3 shows the conditions under which resolution advisories are recalculated because of turn status changes.

If the relative vertical velocity changes significantly within two scans of selecting vertical-only resolution advisories, and the chosen advisories are ineffective based on the current relative vertical velocity, then resolution advisories are recalculated. RAER is called and double dimension resolution advisories are requested. Table 12-4 shows the conditions under which changes in the relative vertical velocity of the pair cause a recalculation of resolution advisories. If RAER is unable to select resolution advisories, the previously selected advisories continue to be given.

12.3.2.3 Controlled/Uncontrolled Conflict Pair

When an ATARS-equipped controlled aircraft and an equipped uncontrolled aircraft are declared in conflict by the detection logic, normally the uncontrolled aircraft is maneuvered without maneuvering the controlled aircraft. This is accomplished by using larger detection thresholds to determine the need for the uncontrolled aircraft's advisory than are used to determine the need for the controlled aircraft's advisory. However, if it is determined on a later scan that the controlled aircraft should be maneuvered, RAER is called to compute advisories for both aircraft. The PIFR flag is set in the Pair Record to indicate that the controlled aircraft should receive an advisory.

If the Resolution Advisories Evaluation Routine is able to compute advisories for both aircraft, then the PIFR flag remains set in the Pair Record. If RAER is not able to compute an advisory for the controlled aircraft, PIFR is reset and resolution is delayed. If this pair is being processed by

Normal Master Resolution, then resolution is delayed by setting an Encounter List flag appropriately so that this pair will be processed by Delayed Master Resolution. This will give the Resolution Advisories Evaluation Routine a second chance on this same scan to try to compute an advisory for the controlled aircraft. The advisory to the uncontrolled aircraft should not be deleted from the Pair Record even if an advisory to the controlled aircraft can not be added.

12.3.2.4 Positive/Negative Resolution Advisory Transition

Resolution advisories are monitored to determine if a negative-to-positive transition is required or a positive-to-negative transition is allowed. If either transition may occur, new resolution advisories are selected and entered in the Pair Record. When positive resolution advisories are selected they must continue for at least TSCMD seconds before a transition may occur. If positive resolution advisories have been issued in both planes for the given pair and the resolution advisories in one plane transition to negatives, the resolution advisories in the other plane are deleted.

Horizontal resolution advisories are checked for possible transition by comparing the miss distance calculated by the Detect Task against the negative horizontal resolution advisory threshold. If the miss distance is less than the threshold, then positive resolution advisories are needed. Otherwise, negative resolution advisories are acceptable. The normal negative horizontal resolution advisory threshold is modified (increased) if either aircraft is turning.

Vertical resolution advisories are checked for possible transition by comparing the current vertical separation against the negative vertical resolution advisory threshold. If the current altitude separation is greater than the threshold, and the aircraft are diverging vertically, then positive vertical resolution advisories may transition to negatives.

If the current altitude separation is less than the threshold, then an additional check is performed before requiring negative verticals to transition to positives. The current altitude separation must be less than a parameter (ATBZP) percent of the threshold before the transition to positives is required.

If the Pair Record contains resolution advisories of a different severity (positive/negative) than those determined necessary by the transition logic, then the Resolution Advisories Evaluation

Routine is called to select new resolution advisories. The one exception to this rule is if negative vertical resolution advisories are deemed acceptable and negative vertical resolution advisories are already in the Pair Record. Then, the vertical speed limit (VSL) evaluation logic is performed.

12.3.2.5 Non-responding Aircraft Logic

Additional logic provides for selecting double dimension resolution advisories when either or both aircraft have not adequately responded to the positive single dimension resolution advisories previously computed. A test for non-response to resolution advisories is performed until the aircraft have had a chance to respond to the resolution advisories. Response is not evaluated until TRECOM seconds after resolution advisory selection. Non-response to resolution advisories is inferred if the miss distance in the resolution dimension decreases from one scan to the next. RAER is called and double dimension resolution advisories are requested. If RAER is unable to select new advisories, the previously selected advisories are not deleted.

12.3.3 Resolution Advisories in the Pair Record and Conflict Table

After calling RAER to select resolution advisories, master resolution must record the advisories selected, or handle the pair properly if no advisories were selected.

When RAER returns resolution advisories to the Master Resolution Task, they are first compared with the advisories that are currently in the Pair Record (if any exist). If this is the initial selection of advisories, or any of the advisories have changed from the previous scan, then the new advisories are stored in the Pair Record. Also, the POSCMD field is set appropriately, TSTART is set to the current time, the current horizontal and vertical miss distances are saved and the advisories are flagged to be sent to the aircraft. To facilitate the PSEP model validation logic, the turn status of both aircraft and relative vertical velocity are saved. If the new advisories were selected because of the PSEP model validation logic, then MVDONE is set to \$TRUE. Otherwise, it is set to \$FALSE.

After storing the advisories in the Pair Record, both aircraft's Conflict Table Entries are updated. The fields MULTH and MULTV are set to the number of conflict pairs contributing to the

horizontal and vertical advisories for each aircraft. The Conflict Table Entry fields HMAN and VMAN are set to the effective horizontal and vertical maneuvers. The effective maneuvers are determined by examining every Conflict Table Entry with an advisory for either aircraft and combining the advisories using the logic in Tables 12-5 and 12-6. It should be noted that the effective vertical resolution advisory determination logic shown in Table 12-6 is used only for the Conflict Table Entry field VMAN. The field VMAND may take on additional values. These additional values are determined by the RAR Processing Task (Section 5.2).

Any advisories currently in the Pair Record remain in the Pair Record when RAER is unable to select new resolution advisories. This is true if the pair is being processed by either Master Resolution Normal or Delayed.

12.4 Pseudocode for Master Resolution Task

The high- and low-level pseudocode for the Master Resolution Task is presented in this section.

The low-level pseudocode uses a shorthand pointer notation. Rather than use a pointer name pointing to a data structure, the effective pointer is used in place of the name of the data structure. For example, on page 12-P11, the notation TPREC.acl.PAC.ACID is used. This is shorthand for TPREC(pointer) pointing to PREC.acl.PAC(pointer) pointing to CTENTRY.ACID (note Appendix C).

Another convention is used within LOOPS. The current value of the variable that is the index of the LOOP is denoted in one of two ways. If the variable has a number suffix (1 or 2), the suffix is dropped within the LOOP. If the variable does not normally have a suffix, it is given the prefix T (e.g., TPREC is used for PREC).

13. RESOLUTION ADVISORIES EVALUATION ROUTINE

The Resolution Advisories Evaluation Routine (RAER) is called to determine resolution advisories for a pair of aircraft requiring resolution by the Master Resolution Task or to compute resolution advisories for the controller alert function of the Conflict Resolution Data Task. RAER receives as input an Encounter List entry, the altitude separation threshold, a flag indicating whether single or double dimension resolution advisories are requested, and a flag indicating whether the Master Resolution Task (Section 12) or the Conflict Resolution Data Task (Section 11) is calling this routine. A Pair Record is also provided to RAER when it is called by the Master Resolution Task. The routine generates positive or negative horizontal or vertical resolution advisories, positive double dimension resolution advisories or vertical speed limit (VSL) resolution advisories for each aircraft that is to be maneuvered. The major functions of the Resolution Advisories Evaluation Routine are presented in Table 13-1.

RAER provides resolution for a conflict pair by selecting the "best" set of resolution advisories from a predetermined master list of advisories. This master list of advisories is conceptually divided into three groups: resolution advisory sets that maneuver only the first aircraft; sets that maneuver only the second aircraft; and sets that maneuver both aircraft. Tables 13-2 and 13-3 show how the maneuvering aircraft are determined.

Each of these three groups is further divided into three subgroups: resolution advisory sets with horizontal-only advisories; sets with vertical-only advisories; and sets with double dimension advisories.

"Best" is defined as being that set of advisories that meets certain minimum criteria and surpasses the minimum criteria in more ways than any other potential resolution advisory set.

Only positive resolution advisories are included in the master list of resolution advisory sets. Negative advisories are a special case of positives and are signified by setting a flag associated with a resolution advisory set. The negative resolution advisory that replaces a positive resolution advisory is actually the negative of the opposite sense advisory. Thus the negative of climb is don't descend. The negative of turn right is don't turn left.

TABLE 13-1

MAJOR FUNCTIONS PERFORMED BY THE
RESOLUTION ADVISORIES EVALUATION ROUTINE

Resolution Advisories Evaluation Routine

1. Determine which aircraft to maneuver
 - Select direction of vertical resolution advisories if both aircraft are maneuvered
2. Select list of potential resolution advisories that maneuvers the appropriate aircraft
3. Determine if a positive vertical advisory should be modified because of proximity to terrain
4. Calculate predicted separation based on response to potential resolution advisories
5. Determine if the negative sense of any of the resolution advisories is acceptable
 - Modify those resolution advisories for which negatives are acceptable
 - Calculate vertical speed limit advisories as possible replacements for any negative vertical advisories
 - Modify those negative vertical advisories for which vertical speed limits are acceptable

TABLE 13-1
(Concluded)

6. Evaluate absolute features for all potential resolution advisory sets
 - If none of the potential resolution advisory sets has all absolute features set to true, perform multi-aircraft conflict resolution logic
 - If none of the potential resolution advisory sets has all absolute features set to true, indicate no selection of advisories for now
 - If more than one set of advisories has all absolute features set to true, perform relative features evaluation
 - If more than one set of advisories is tied for the "best," perform tie-breaking features evaluation

TABLE 13-2

WHICH AIRCRAFT TO MANEUVER WHEN NEITHER IS IN FINAL APPROACH ZONE

AIRCRAFT 2	AIRCRAFT 1

Controlled Unequipped	AC1	Neither	AC1	Neither
Uncontrolled Equipped	AC2 ¹	AC2	Both	AC2
Uncontrolled Unequipped	AC1	Neither	AC1	Neither

¹Both aircraft will be maneuvered if PIFR is set.

TABLE 13-3

WHICH AIRCRAFT TO MANEUVER WHEN AIRCRAFT 2 IS IN FINAL APPROACH ZONE

<u>AIRCRAFT 2</u>	<u>AIRCRAFT 1</u>			
	Controlled Equipped	Controlled Unequipped	Uncontrolled Equipped	Uncontrolled Unequipped
Controlled Equipped	AC1	AC2	AC1	AC2
Controlled Unequipped	AC1	Neither	AC1	Neither
Uncontrolled Equipped	AC1	AC2	AC1	AC2
Uncontrolled Unequipped	AC1	Neither	AC1	Neither

Rule to determine which aircraft to maneuver:

If one of the aircraft is on final approach:

1. Give resolution advisories to the aircraft not on final approach if it is equipped.
2. Give resolution advisories to the aircraft on final approach if the other aircraft is unequipped.

Besides including only positive resolution advisories in the master list of advisory sets, another restriction is placed on the vertical resolution advisories for the sets with both aircraft maneuvered. Rather than including all four possible vertical-only advisory sets, and therefore 16 sets of double dimension advisories, only one vertical-only advisory set is included. This is done by allowing the vertical resolution advisories to be selected dynamically for the case in which both aircraft are maneuvered. The master list of resolution advisories and its associated data structure are discussed in Section 13.1. By keeping the master list of advisories as small as possible, the computation time for RAER is minimized.

13.1 Resolution Advisory Data Structure (RADS)

The data structure for a resolution advisory set is described in pseudocode in Section 13.5. Some of the data fields describe intrinsic properties of each resolution advisory set and are "hardwired," while others depend on the encounter and are computed by RAER. The fields that are "hardwired" are shown in Table 13-4.

When both aircraft are expected to respond to resolution advisories, there is normally one "best vertical" resolution advisory set. This "best vertical" resolution advisory set can be found by projecting the aircraft ahead eight seconds and giving the aircraft on top a climb and the one below a descend. For the resolution advisories that maneuver both aircraft in the vertical dimension, the vertical maneuvers are not "hardwired," but are computed using this "eight second rule." The same is not done when only one aircraft is maneuvered because it may be desirable to maneuver one aircraft vertically toward another to avoid a vertical chase.

The "eight second rule" as described above is used only on the first scan in which vertical resolution advisories are selected for a pair of maneuvering aircraft. Once vertical advisories have been selected, on subsequent scans the same vertical sense must be maintained.

The selection of the "best vertical" resolution advisories for a pair of aircraft should not be confused with the selection of the "best" resolution advisory set for a conflict pair. The selection of the "best vertical" advisories only determines which vertical advisory should be considered for each aircraft to resolve the conflict.

TABLE 13-4

FIELDS IN THE RESOLUTION ADVISORY DATA
STRUCTURES THAT ARE "HARDWIRED"

<u>RESOLUTION ADVISORY DATA STRUCTURE FIELD</u>	<u>INITIAL VALUE</u>
CMDED_CMDED	Set if this advisory set contains advisories for both AC; reset otherwise
CMDED_UNCMDED	Set if this advisory set contains advisories for the first AC only, reset otherwise
HORIZ	Set if this advisory set contains a horizontal advisory; reset otherwise
H1	Horizontal resolution advisory for first AC, or null if this AC not maneuvered
H2	Horizontal resolution advisory for second AC, or null if this AC not maneuvered
INDEX1	Set to reference the appropriate entries in the PSEP, QSEP, and HMD matrices that correspond to the horizontal advisory in this advisory set for the first AC
INDEX2	Set to reference the appropriate entries in the PSEP, QSEP, and HMD matrices that correspond to the horizontal advisory in this advisory set for the second AC
INDEX3	Set to reference the appropriate entries in the PSEP, QSEP, VMDB, and VMDA matrices that correspond to the vertical advisory in this advisory set for the maneuvered AC, regardless of whether one or both AC are maneuvered
MATPTR	Set to point to the set of separation matrices to be used with the resolution advisory set. In Two-aircraft Resolution logic there is only one set of matrices. There may be two sets of matrices in the Multi-aircraft Resolution logic.

TABLE 13-4
(Concluded)

<u>RESOLUTION ADVISORY DATA SET FIELD</u>	<u>INITIAL VALUE</u>
NXTADV	Points to next data structure in list
SINGLE	Set if this advisory set has only single dimension advisories; reset if this advisory set has double dimension advisories
UNCMDED_CMDED	Set if this advisory set contains advisories for the second AC only; reset otherwise
VERT	Set if this advisory set contains a vertical advisory; reset otherwise
V1	Vertical resolution advisory for first AC if only first AC maneuvered, null if first AC not maneuvered, or uninitialized if both AC maneuvered
V2	Vertical resolution advisory for second AC if only second AC maneuvered, null if second AC not maneuvered, or uninitialized if both AC maneuvered

13.2 Predicted Separation Calculations

The predicted separation matrices contain the separations that two conflicting aircraft are expected to achieve by responding to resolution advisories. The separation values are computed by performing a fast-time simulation and modeling the performance of the aircraft. This simulation begins with a short delay period (to account for communication and pilot response delays), during which only sensed turns and previous advisories are modeled. This is followed by a maneuver period, during which the aircraft are modeled as responding to the various resolution advisory sets under consideration for the present conflict.

During the fast-time simulation, the minimum values for three-dimensional (3-D) separation (slant range), two-dimensional horizontal separation (range), and vertical separation are recorded in the predicted separation matrices for the various combinations of maneuvers modeled for the aircraft. The 3-D closest approach point, horizontal closest approach point, and vertical closest approach point may occur at different times.

13.2.1 Predicted Separation Data Structures

The predicted separation data structures consist of five matrices: HMD, VMDA, VMDB, PSEP, and QSEP. The first four of these matrices contain minimum separation values: horizontal separation in HMD, vertical separation in VMDA and VMDB, and 3-D separation in PSEP. The QSEP matrix contains 3-D separation values for a particular instant in time.

The HMD matrix is a 3x3 array. Each element represents the minimum horizontal separation for a particular combination of horizontal flight paths for the two aircraft. For computational efficiency, the square of the range is stored, in units of nmi^2 . The first dimension of HMD corresponds to the three horizontal maneuvers turn left (TL), continue straight (CS), and turn right (TR) for one aircraft. The second dimension corresponds to the same three horizontal maneuvers for the other aircraft. Each of the three horizontal maneuvers for one aircraft combines with those for the other aircraft, giving a total of nine combinations. These nine combinations model all possible horizontal resolution advisory sets. Negative horizontal resolution advisories are not explicitly modeled, but are considered to be represented by the CS path.

All nine horizontal combinations are not always formed. When only one aircraft is to be maneuvered, only the CS path is modeled for the other aircraft. If an aircraft has a positive horizontal advisory in the HMAN field of its Conflict Table Entry, then the path corresponding to the opposite-sense positive advisory need not be modeled, since such an incompatible advisory cannot be selected. For instance, if an aircraft has a previous turn left advisory in its HMAN field, then the turn right path need not be modeled. In the case of previous negative horizontal advisories, however, no paths can be eliminated, since they are all needed by the negative resolution advisory determination logic.

The VMDA matrix is a one-dimensional three-element array. Each element represents the minimum vertical separation for a particular combination of vertical flight paths for the two aircraft. Unlike the horizontal advisories, not all combinations of vertical resolution advisories are valid; therefore, only a total of three combinations is considered. (Each of these three combinations will hereafter be referred to as a vertical "level.")

Vertical level one always represents both aircraft projected ahead with their current vertical rates. The meaning of the other two levels will depend upon which aircraft are to be maneuvered. If both aircraft are to be maneuvered, then level two will correspond to the vertical resolution advisories picked by the "eight second rule," as described previously in Section 13.1, and level three will correspond to the negative of these resolution advisories. Note that negative vertical advisories are explicitly modeled in this case. If only one of the aircraft is to be maneuvered, levels two and three take on different meanings. In this case, vertical level two will represent a descend advisory for the maneuvered aircraft, and level three will represent a climb advisory for that aircraft. The unmaneuvered aircraft will be projected ahead with its current vertical rate for all three levels. Negative vertical advisories are not explicitly modeled in this case.

There is one exception to the above rules for determining vertical levels. When it is desired to model a descend for an aircraft which is less than a distance ATERN above the terrain threshold, a don't climb is modeled instead. Table 13-5 summarizes the definitions of the three vertical levels for all of the cases described above.

TABLE 13-5
PSEP VERTICAL LEVELS

Both Aircraft Maneuvered

- LEVEL 1: Project both aircraft ahead with their current vertical rates.
- LEVEL 2: Project each aircraft ahead following positive vertical resolution advisory chosen by "eight second rule."¹
- LEVEL 3: Project each aircraft ahead following negative of vertical resolution advisory chosen by "eight second rule."

Only One Aircraft Maneuvered

- LEVEL 1: Project both aircraft ahead with their current vertical rates.
- LEVEL 2: Descend¹ for maneuvered aircraft, project unmaneuvered aircraft ahead at current vertical rate.
- LEVEL 3: Climb for maneuvered aircraft, project unmaneuvered aircraft ahead at current vertical rate.

¹Descend is modeled as don't climb if aircraft is less than ATERN above the terrain threshold.

The PSEP matrix is a 3x3x3 array. Each element represents the minimum 3-D separation for a particular combination of both horizontal and vertical flight paths for the two aircraft. In computing the separation values, the vertical separation component is weighted by a factor of VWEIGHT. As was the case with the HMD matrix, the square of each separation value is stored, in units of nmi^2 . The first two dimensions of PSEP are the same as the dimensions of HMD. That is, they represent the horizontal flight paths which are modeled for the two aircraft. The third dimension corresponds to the three vertical levels, as previously described for the VMDA matrix. For modeling vertical-only resolution advisories, aircraft are considered to follow the CS path horizontally.

The VMDB matrix is also a one-dimensional three-element array. Like VMDA, each element contains a vertical separation value for one of the three vertical levels. Unlike VMDA, however, the elements of VMDB represent achievable separations, rather than absolute minimum separations, for single vertical advisories. Each value is computed to be the unweighted vertical component of the minimum 3-D separation for the vertical-only maneuvers represented by the level.

The QSEP ("quick separation") matrix is another 3x3x3 array. Each element is a vertical-weighted 3-D separation value, and the dimensions of QSEP are defined the same as for the PSEP matrix. When the aircraft have been modeled as responding to new resolution advisories for a short period of time (defined by the QTIME parameter), the instantaneous 3-D separation values are saved in the QSEP matrix. Thus, the QSEP matrix represents a "snapshot" of separation values shortly after the aircraft have begun to maneuver in response to resolution advisories. QSEP values are occasionally used as a final tie-breaker in choosing the best resolution advisory set.

13.2.2 Modeling of the Delay Period

In order to account for communication and pilot response delays, the modeling of the aircraft begins with a short delay period. The delay period models the aircraft for a constant length of time, specified by the DELAY parameter. During this period it is assumed that the advisories being considered for the present conflict will not yet be effective. Therefore, only turns strongly sensed by the tracker and resolution advisories issued previously will affect the modeled flight paths. If any such sensed turn or previous advisory is in effect for either aircraft, then nonlinear flight is assumed. In this case, the

delay period is modeled with a fast-time simulation; the length of each time step is specified by the DELINT parameter. (DELAY should always be an even multiple of DELINT.) During the first half of the delay period, any sensed turns are modeled for each aircraft. During the last half of the delay period, the aircraft are modeled as responding to any resolution advisories which are currently being displayed (as recorded in the VMAND and HMAND fields of the Conflict Table Entries). Such previous advisories are modeled only during the delay period.

The modeling of sensed turns and previous turn left and turn right advisories during the delay period is performed by assuming a constant bank angle, defined by the parameter BANKA. Previous negative horizontal advisories are not explicitly modeled and do not contribute to nonlinear flight. Previous vertical resolution advisories are modeled by determining a "final" vertical rate which the aircraft is to achieve. If this final vertical rate is different from the aircraft's current rate, the aircraft is accelerated toward the final rate using one of the parameters ACCELC or ACCELD. In the case of positive vertical advisories, the final rate is determined by one of the parameters ZDUPF, ZDUPS, ZDDWNF, or ZDDWNS, depending on the directional sense of the advisory and the aircraft's current velocity. In the case of negative vertical resolution advisories (including VSLs), the previous advisory may contain both upward and downward components. Here the current vertical rate and a pair of vertical rate limits (chosen from Table 13-6) determine the final vertical rate.

In the event that neither aircraft has a sensed turn nor a previous resolution advisory, then linear flight is assumed during the delay period. In this case, both aircraft are simply projected straight ahead for DELAY seconds, using their current velocity components.

During the modeling of the delay period, only one flight path is modeled for each aircraft. The result of this modeling is a set of four minimum separation values: PSEPI, HMDI, VMDAI, and VMDBI. These values are used to initialize all elements of the PSEP, HMD, VMDA, and VMDB arrays, respectively, for the modeling of the maneuver period.

13.2.3 Modeling of the Maneuver Period

The maneuver period is modeled with a fast-time simulation, in a series of time steps. The length of each step is given by the TIMINT system parameter, which is chosen to be an integral divisor of the sensor scan time (SCANT). During the maneuver

TABLE 13-6

MAXIMUM AND MINIMUM VERTICAL RATE PARAMETERS FOR
MODELING NEGATIVE VERTICAL RESOLUTION ADVISORIES

Limit Descent 1000 ft/min	-V1000
Limit Descent 2000 ft/min	-V2000

period, multiple flight paths are modeled for each aircraft, as previously explained. The expected response of the aircraft to each resolution advisory is modeled, and the minimum separation values between the aircraft are computed. Resolution advisories are modeled in the same way as described for previous advisories during the delay period (see Section 13.2.2), except that VSLs are never modeled during the maneuver period. As the predicted positions and velocities are determined, certain of these values are saved in the Resolution Advisory Projected Position (RAPP) Table to be used by the Domino Feature (see Section 13.4.2.4). All elements of the RAPP Table are set to an uninitialized value before the predicted separation calculations begin. This is done so that if the domino logic tries to use values that have not been calculated, this condition can be recognized and the projection calculations may then be performed.

When QTIME seconds have passed in the modeling of the maneuver period, the instantaneous values of 3-D separation for all combinations of flight paths are saved in the QSEP matrix, as previously explained. These values are used in certain cases as a final tie-breaker in determining the best resolution advisories (see Section 13.4.3).

The maneuver period is modeled for a fixed length of time, MANTM. MANTM is calculated basically as follows: First, the time to 3-D closest approach (vertical weighted) is calculated after the delay period, assuming straight flight for each aircraft. To this value a parameter (TCADEL) is added. This result is replaced by a fixed value if the aircraft are slow-closing. Next, an upper limit is applied. This limit is computed so as to not allow either aircraft to be modeled through a turn of more than TURN1, nor to allow both aircraft to be modeled through a combined turn of more than TURN2. Finally, fixed upper and lower limits of MTUL and MTLL, respectively, are applied.

For some geometries the aircraft will still be converging at the end of MANTM. For these geometries, the measured minimum separation will be larger than the true closest approach. Separate tests are applied to determine 3-D, horizontal, and vertical convergence.

The VMDA matrix is used for determining if negative resolution advisories give sufficient separation. Negative vertical resolution advisories should not be issued that will allow the aircraft to converge. Therefore, an entry in VMDA is set to

zero if vertical convergence is indicated. Likewise, if three-dimensional convergence is indicated at MANTM, then PSEP is set to zero if the resolution advisory set contains a horizontal maneuver. For vertical maneuvers only, PSEP is calculated by a three-dimensional miss distance formula. Similarly, if horizontal convergence is indicated at MANTM, then HMD is computed from a horizontal miss distance formula for the center element of the HMD matrix (no horizontal maneuvers) or set to zero for any other element (at least one horizontal maneuver).

13.3 Negative Resolution Advisories Evaluation

The RAER logic selects positive resolution advisories in the horizontal or vertical dimension and then, in some cases, modifies those resolution advisories to negative. If RAER determines that negative resolution advisories provide sufficient separation, the NEGATIVE flag is set in the Resolution Advisory Data Structure.

13.3.1 Horizontal and Vertical Negative Resolution Advisories

Reference to the negative of a resolution advisory always means the negative of the opposite direction advisory. That is, the negative of a turn left is don't turn right. The negative of turn right is don't turn left. The negative of climb is don't descend, and the negative of descend is don't climb.

When the vertical dimension has been selected for resolution, negative vertical resolution advisories are selected if the vertical predicted separation at the time a pilot responds is greater than the positive resolution advisory altitude separation (ASEP) and the aircraft will not converge to less than ASEP during the projection interval. If both aircraft are maneuvered, negative vertical advisories are explicitly modeled. This is not true if only one aircraft is maneuvered. If only one aircraft is maneuvered, both the climb and descend advisories will be examined. If the advisory will maneuver that aircraft into the unmaneuvered aircraft, then the negative of that advisory is not acceptable, since the negative advisory would still allow the aircraft to maneuver into the unmaneuvered aircraft. If the advisory will maneuver the aircraft away from the unmaneuvered aircraft, then the separation achieved by the positive advisory is checked. If the positive sense of the advisory will prevent the aircraft from coming closer than ASEP, then the negative is acceptable, since the negative is

essentially a level-off advisory in this particular altitude geometry. The negative is acceptable only if the unmaneuvered aircraft does not have a large vertical rate towards the maneuvered aircraft.

When the horizontal dimension has been selected for resolution, negative horizontal resolution advisories are selected if the horizontal predicted separation along each of the possible response paths is greater than the positive resolution advisory horizontal miss distance threshold (MDTHSQ). To check if negative horizontal resolution advisories give sufficient separation, four HMD values must be examined if both aircraft are maneuvered, and two HMD values must be examined if only one aircraft is maneuvered.

If both aircraft are maneuvered, negative advisories are not selected unless the predicted separations are greater than MDTHSQ for all of the following cases:

1. Both aircraft perform the positive maneuver being evaluated
2. Either aircraft performs the positive maneuver; the other continues straight
3. Neither aircraft performs the positive maneuver

For example, if turn left/turn left is the advisory set being examined, then the HMD values of turn left/turn left, turn left/continue straight, continue straight/turn left and continue straight/continue straight must all be greater than MDTHSQ if the NEGATIVE flag is to be set indicating a don't turn right/don't turn right advisory combination is acceptable for resolution.

If only one aircraft is maneuvered, the predicted separation values of two HMD entries are checked. If turn left is the advisory being examined, then the HMD value of the turn left/continue straight and continue straight/continue straight advisories are checked to determine if a don't turn right would be a sufficient advisory to the maneuvered aircraft. The value of MDTHSQ is modified (increased) if either aircraft is turning.

Double dimension advisories are not checked for the possibility of giving negative advisories. When single dimension advisories are checked for negatives being sufficient, a check for positive or negative advisories to both aircraft (assuming both

maneuvered) is always made. The logic will not issue a positive advisory to one aircraft and a negative to the other, except for the one case where the aircraft to receive a descend advisory is less than ATERN feet above the terrain threshold. In this case the BELOW1000 flag is set, indicating that the descend should be changed to a don't climb. The H1, V1, H2, and V2 fields of the selected resolution advisory should be modified, if necessary, because of the NEGATIVE flag or the BELOW1000 flag.

13.3.2 Vertical Speed Limit (VSL) Advisories Evaluation

If negative vertical resolution advisories are selected for both aircraft, additional logic determines if a limit vertical rate advisory can be used to resolve the conflict. That is, will a "limit descent to some rate" suffice versus a don't descend (i.e. limit vertical rate to zero). VSL advisories are considered to be a subset of negative vertical resolution advisories.

The desired vertical speed limit is computed based on the current altitude separation, current vertical velocity, expected pilot delay time, and desired separation at the projected closest separation time. Speed limits are computed for each aircraft assuming that there is no change in the direction and velocity of the other aircraft. To receive a VSL, an aircraft must be maneuvering vertically faster than the minimum rate (MRATE) and the direction of the aircraft's current vertical velocity must be towards the other aircraft.

VSLs are computed individually for each aircraft of the pair. Consequently, only one or both may receive VSLs or different VSLs may be given to each one. The computed VSL is rounded down to 2000 ft/min, 1000 ft/min, or 500 ft/min. If a VSL resolution advisory is selected, it is assigned to the vertical field in the Resolution Advisory Data Structure.

13.4 Features Evaluation

After determining which subset of the master list of potential resolution advisories is applicable to the subject conflict pair, the subset must then be reduced to a single advisory set that will resolve the conflict. The first step in this reduction process was calculating the projected separations in response to the various resolution advisories. The projected separations were then used to determine if the negative of any of the single dimension advisory sets will provide sufficient

separation. Then the projected separations and the response paths are used to determine which advisory set will resolve the conflict better than the other advisory sets.

The resolution advisory sets are evaluated by applying a number of sequential tests, called features. If a feature is true (i.e. passes the test) for a given advisory set then the feature is said to be "set." The outcome of the tests may depend on the geometry of the encounter, the speeds of the aircraft, the predicted separation, or many other factors. The pseudocode for the Relative Features Evaluation Process in Section 13.5 shows these tests in order of precedence. Tables 13-7 and 13-8 provide the logic for the resolution advisory compatibility and reinforcement checks, which are used by some of the features.

Although alternative implementations are possible, this discussion refers to the tests as individual routines that operate on the list of resolution advisories. Each test has a weight associated with it, the most important test having the highest weight. These weights are stratified so that the weight of a test is greater than the sum of the weights for the less important tests. This could be accomplished by using sequential powers of two for the weights. When a resolution advisory satisfies or passes a test or feature, its VALUE field is increased by the weight for that test. The resolution advisory with the highest number in its VALUE field is considered the best resolution advisory. The RADS data structure is general enough to allow an efficient implementation in most programming languages. The implementation should be made flexible enough to allow new tests to be added and the list reordered without a major redesign.

To reduce computation time, the list could be pruned after some of the tests. For example, the test that decides whether to favor single or double resolution advisories is guaranteed to cut the list to about half of its size, if all of the previous tests are equal. By eliminating all of the resolution advisories that are not tied with the highest value, the amount of computer processing time could be reduced. Whether or not this savings is significant depends on the implementation. This pruning of the list can be done only after all of the features with higher weights have been evaluated.

13.4.1 Absolute Features

The first three features, the Deliverable, Dimension Available and Manuevered/Unmanuevered Conflict Features, are called absolute features. As the name absolute implies, each of these

RESOLUTION ADVISORY COMPATIBILITY LOGIC

						0	0	0	0	0	0

1 = Reinforces, 0 = Does not reinforce
Each dimension of double dimension resolution advisory sets is tested separately.
If either dimension reinforces the previous set, then the new advisory set reinforces the previous advisory set.

features must be set true for the resolution advisory set that is selected to resolve the conflict pair. If none of the advisory sets has all three absolute features set, then no advisory set is selected to resolve the conflict.

13.4.1.1 Resolution Advisory Compatibility and Deliverability

The Deliverable Feature determines if the resolution advisories can be delivered to the aircraft. This feature is set true if, on the first scan that advisories are selected for a conflict pair, either the advisories are flagged as negatives or they provide a minimum separation greater than that which would be obtained if no advisories were sent to the aircraft. On subsequent scans of advisory selection, this feature is automatically set true.

The Dimension Available Feature determines if the resolution advisories will be accepted by the ATARS avionics. This feature is set true only if the advisories for both aircraft are compatible with all other advisories previously selected for each of the aircraft. The compatibility logic in Table 13-7 is used by this feature.

The Manuevered/Unmanuevered Conflict Feature checks for a maneuvered aircraft in the current conflict being unmanuevered in another conflict pair. If this situation is detected, then this feature is reset for any advisory sets that have a component in the same dimension as that used to resolve the previous conflict. This is done because the resolution for the previous pair was based on one of the aircraft not maneuvering. It is not yet known how a maneuver would affect the previous conflict.

The Deliverable Feature is the only absolute feature evaluated when RAER is called by the Conflict Resolution Data Task. When RAER is called from the Master Resolution Task, all three absolute features must be evaluated.

If either or both of the aircraft in a conflict are also in one or more other conflicts, then it is possible that resolution advisories given to the aircraft for the other conflicts restrict the selection of advisories for the current conflict to the point where none of the potential resolution advisory sets has all of the absolute features set. If this occurs, then the multi-aircraft resolution logic is used to attempt to select resolution advisories for the pair. The multi-aircraft resolution logic will not be performed when RAER is called by

the Conflict Resolution Data Task. This is ensured by overriding the outcome of the Deliverable Feature, if this is necessary to obtain a resolution advisory set with all absolute features set to true. The multi-aircraft logic can be performed only if both aircraft are to be maneuvered. Otherwise all possible resolution advisory sets have already been examined.

13.4.1.2 Multi-aircraft Resolution Logic

The multi-aircraft resolution logic first determines why no advisory sets have all absolute features set. For any advisory sets with the Deliverable and Dimension Available Features set, the Maneuvered/Unmaneuvered Conflict Feature is evaluated using the multi-aircraft definition. If all absolute features are set true for any advisory sets after the re-evaluation, then resolution advisories can be given this scan. Otherwise, additional logic is executed in an attempt to increase the number of advisory sets being examined for selection.

If only one aircraft is to be maneuvered for the current conflict, then all possible resolution advisory sets have been examined. Attempts to resolve the pair are delayed until later this scan or until the next scan. However, RAER will not be able to select advisories for the current conflict pair until the conditions preventing advisory selection change.

If both of the aircraft in the current conflict are to be maneuvered, then the multi-aircraft resolution logic looks at vertical advisories other than the "best vertical" set. If the aircraft are currently within ZCARE feet vertically, then vertical advisories opposite to the "best vertical" are examined. If the aircraft are currently separated by more than ZCARE, both aircraft are given the same vertical advisory. Both climb and descend to each aircraft are examined. All possible double dimension advisory sets are also considered.

The absolute features for the new advisory sets are then evaluated using the multi-aircraft definition of the Maneuvered/Unmaneuvered Conflict Feature. If any advisory set has all absolute features set, then resolution advisories will be selected this scan. Otherwise, resolution is delayed.

13.4.2 Relative Features

The following features are called relative features. They are used only to select one potential resolution advisory set over another as the "better" set of resolution advisories. None of

these features must necessarily be set true for the advisory set that is selected to resolve the pair.

The relative features evaluate such things as the projected separation against certain thresholds, the current separations against certain thresholds, and the current horizontal or vertical velocities against the other aircraft or against certain thresholds. Also evaluated is an advisory's ability to reinforce the advisory given to this pair on the previous scan, advisories given to either aircraft from other ATARS sites or BCAS, and the turn status of the aircraft.

13.4.2.1 Predicted Separation Dependent Features

Some of the features examine the predicted separation in response to advisories. The top priority relative feature (PSEP GE SEP1) checks for separation greater than a minimum desirable separation. Any advisory set providing at least this separation has this feature set.

A lower priority feature (PSEP GE SEP2) checks for a larger predicted separation, SEP2. There are two SEP2 values, which are computed dynamically. One value is used for single dimension advisories and the other for double dimension advisories. Each value is a percentage of the maximum separation provided by any single (double) dimension advisory with all absolute features set.

Two low priority features consider the predicted miss distance in the resolution dimension. If a vertical advisory set will provide large separation, the Big Vertical Miss Distance Feature is set. If a horizontal advisory set will provide large separation, the Big Horizontal Miss Distance feature is set. These two features provide the only exception to the rule that all features have different weight. If either feature is set, the other feature is also set. This effectively gives both features the same weight.

13.4.2.2 Aircraft Geometry and Velocity Dependent Features

Certain relative features consider the conflict pair's geometry. If one aircraft is not maneuvered and that aircraft has a large vertical velocity or a speed much greater than that of the other aircraft, then the Unmaneuvered With Large Vertical Rate Feature or the Fast Unmaneuvered/Slow Maneuvered Feature is set for those resolution advisory sets containing double dimension advisories.

Another feature tests the speed of each aircraft. If either maneuvered aircraft has a large velocity or if both aircraft are slow, then all PRAs with horizontal advisories have the Speed Check Feature set.

If either of the aircraft is receiving a terrain or obstacle alert, the Terrain Or Obstacle Alert Feature is set true for all horizontal-only resolution advisory sets.

13.4.2.3 Aircraft Maneuverability Dependent Features

Some of the features consider the aircraft's maneuverability with respect to horizontal turn status and vertical rate status and with respect to previous resolution advisories.

If either of the maneuvered aircraft has a previous horizontal advisory, then the Reinforce Resolution Advisory From Non-Connected Site or BCAS Feature or the Reinforces Prior Resolution Advisories Feature is set true for any advisory set with a compatible horizontal resolution advisory. Similarly, the Reinforces Turn Feature is set true for any advisory set with a horizontal maneuver that reinforces a sensed turn for either maneuvered aircraft. The logic in Tables 13-9 and 13-10 is used by these and other features to determine compatibility of horizontal advisories with turn status and vertical advisories with vertical velocity.

13.4.2.4 Domino Feature

When an aircraft is given a resolution advisory, it is possible that by executing that maneuver, the aircraft will be directed into another conflict requiring resolution advisories. This type of conflict, caused by a resolution advisory, is called a domino conflict. If the second conflict begins before the first conflict is resolved, then there is a multi-aircraft conflict. It is always desirable to avoid domino-created multi-aircraft conflicts, if at all possible. A way to avoid a domino-caused multi-aircraft conflict is to model an aircraft's response to a resolution maneuver and determine if a conflict requiring resolution advisories will be created with another aircraft during the time the aircraft is responding to the resolution advisory. Then, if there is more than one set of acceptable resolution advisories for resolving a conflict, the set of resolution advisories that does not cause a domino multi-aircraft conflict should be the set of resolution advisories chosen. Logic that performs the checks for detecting a domino-caused multi-aircraft conflict is called the domino logic.

The domino logic is called by the RAER during evaluation of the relative features. Two features are controlled by the outcome of the domino logic. The most desirable situation, and therefore the higher priority of the domino features, is for neither aircraft to be predicted as being involved in a domino conflict because of the subject resolution advisories. The next domino feature is set if only one aircraft is predicted to be in a domino conflict because of response to its resolution advisory. The remaining possibilities are that both aircraft are predicted to be in a domino conflict because of their resolution advisories, or that domino logic is not performed for this pair of aircraft. In these two cases, neither of the domino features is set.

The domino logic must determine all potential resolution advisories available to each aircraft. The potential resolution advisories are needed by the Domino Coarse Screen Filter (Section 13.4.2.4.2) to determine the extent of the search limits. This logic selects all aircraft that are within the search limits and creates a Potential Domino Conflict List for each of the aircraft requiring resolution advisories.

To determine if a given resolution advisory will cause an aircraft to come into conflict with another aircraft, the aircraft's path in response to the resolution advisory must be modeled. This was done when the predicted separation calculations were performed. The projected positions and velocities at four points (one, two, three, and four scans after the delay period) were stored in the Resolution Advisory Projected Position (RAPP) Table. The domino logic compares these values to the projected positions and velocities of aircraft from the Potential Domino Conflict List using a shortened detection logic. (Previous resolution advisories and tracker sensed turns will be modeled for aircraft on the Potential Domino Conflict List in the same way that these maneuvers were modeled for the subject aircraft.) Since the only concern of the domino logic is for a conflict requiring resolution advisories being created, the resolution advisory checks are the only checks of the detection logic performed. If a domino conflict is determined with any aircraft on the Potential Domino Conflict List, then the remainder of the list need not be checked for another domino conflict caused by the same resolution advisory. The subject resolution advisory is flagged as causing a domino conflict. The domino checks then begin for the next resolution advisory.

The first check performed in the domino logic is to determine which aircraft is (are) maneuvered. This can be done by examining the CMDED UNCMDED and the UNCMDED CMDED flags of the first potential resolution advisory. This information is used in the Domino Coarse Screen Filter.

The Potential Resolution Advisory Domino Status Variables are set by cycling through all the potential resolution advisories that have all absolute features set and whose total value is tied for the highest valued resolution advisory set. There is only one status variable for negative horizontal resolution advisories, since a don't turn left and don't turn right are both equivalent to continue straight.

The Domino Coarse Screen Filter determines a list of potential domino conflict aircraft for each of the subject aircraft that is to receive a resolution advisory. The Domino Detection Filter checks each potential resolution advisory for causing a domino conflict with an aircraft on the Potential Domino Conflict List.

13.4.2.4.1 Domino Logic Data Structures

There are two data structures used by the domino logic. Both are described in the pseudocode in Section 13.5. One data structure (PRADSVVBL) is associated with each maneuvering aircraft in the subject conflict pair. The other data structure (PDC LIST) is associated with each aircraft on the Potential Domino Conflict (PDC) List.

The data structure associated with the subject aircraft contains information on the potential resolution advisories for that aircraft and their status in terms of the domino logic. All of the Potential Resolution Advisory Status Variables are initialized to \$NOTPRA (not a potential resolution advisory). As the Domino Coarse Screen Filter examines the RADS, those status variables corresponding to RADS that have the potential to be selected for resolution are set to \$DOMNP (domino not yet processed). Those advisories with status \$DOMNP are used to determine the domino coarse screen search limits.

As the Domino Detection Filter processes the aircraft on the PDC List, the status variables having the state \$DOMNP transition to the state \$DOMCNC (domino conflict not caused by this resolution advisory) or \$DOMCC (domino conflict caused by this resolution advisory) as appropriate. Then the domino features are set for each RADS based on the final state of the status variables.

The second data structure is associated with each aircraft on the Potential Domino Conflict List. The data structure points to the State Vector of the aircraft, where the Domino Object Projected Positions (DOPP) values are found. These values are used in the Domino Detection Filter. The data structure also points to the next aircraft on the PDC list.

The data structure for the PDC aircraft contains resolution advisory status variables. These variables are initialized to \$NOTTEST (this advisory not tested for causing a domino conflict with this aircraft). After domino detection is performed between a subject and object aircraft for a resolution advisory, the appropriate status variable is set to either \$NODOMC (no domino conflict caused by this advisory with this aircraft) or \$DOMC (domino conflict caused by this advisory with this aircraft).

13.4.2.4.2 Domino Coarse Screen Filter

The Domino Coarse Screen Filter determines a list of potential domino conflict aircraft for each maneuvered aircraft of the subject conflict pair. This is done by calculating the maneuvered aircraft's projected response path to all of the potential resolution advisories during the duration of the conflict, and adding to this the maximum immediate separation threshold distance.

The Domino Coarse Screen Filter performs a forward and backward search along the X-list or EX-list. The distance to be searched along the list is a function of the current speed and heading of the subject aircraft and the potential resolution advisories. The lists searched are also a function of the subject aircraft being on the X-list or EX-list. If the subject aircraft is on the X-list, only the X-list is searched for potential conflict aircraft. If the subject aircraft is on the EX-list, the EX-list is searched. The X-list may also be searched if the aircraft is close to the altitude limit of the X-list or is projected to be within the altitude limit of the X-list within the maximum detection time threshold.

After determining which list the subject aircraft is on, the search limits along that list must be computed. To compute the search limits, the resolution advisory tau threshold and immediate range parameters must be chosen. The maximum values from Table 13-11 are used in the Domino Coarse Screen Filter.

DTCMDV	Same as DTCMDH, except TCONH is replaced by TCONV in the NOMINAL column			

¹See local variable structure DRAVBL in Section 13.5

²C = Controlled U = Uncontrolled

³The value of TCONH, TCONV is calculated in Routine TAU_AND_PROXIMITY_THRESHOLD_DETERMINATION.
If the value of DTCMDx after subtracting the offset is not within the bounds specified by the MINimum and MAXimum columns, then the value of DTCMDx is set to the minimum or maximum value specified.

⁴E = ATARS Equipped U = Unequipped

⁵UUIND is defined in Routine DOMINO_UNCON_UNCON_INDEX_DETERMINATION.

The logic that performed the PSEP calculations also saved projected positions and velocities in response to potential resolution advisories in the RAPP Table. To calculate the coarse screen limits, a TCMDH projection is made from each of the points along the response paths in the RAPP Table.

Once the minimum and maximum x and y projected positions have been calculated, a buffer distance (RMAX) must be added to obtain the actual X-list (EX-list) search limits. The buffer accounts for the object aircraft and is equal to the distance that an aircraft going the maximum speed for the X-list (EX-list) can travel during the resolution advisory response projection interval (MANTM + DELAY) and the resolution advisory detection threshold (TCMDH). The maximum speeds are 240 kts (XVEL) for aircraft on the X-list and 600 kts (EXVEL) for aircraft on the EX-list. A maximum vertical maneuver rate of 1000 ft/min (CSCREEN.ZFAST) is assumed for aircraft on the X-list and EX-list.

The altitude limits used in the Domino Coarse Screen Filter are computed similarly to the horizontal limits. After the search limits have been calculated, the Domino Coarse Screen Filter simply searches along the X-list (EX-list) looking for aircraft that are contained in the x, y and z search limits. Any aircraft within these bounds are added to the Potential Domino Conflict List for the subject aircraft. Any aircraft within the search limits that are already in conflict with and receiving a resolution advisory because of the subject aircraft are not added to the Potential Domino Conflict List.

It is possible for an aircraft to be in more than one conflict on a scan. If this is the case, then it is possible to compute a list of potential domino conflict aircraft twice on the same scan for a particular aircraft. It is best to avoid this duplicate processing if possible. When a list of potential domino conflict aircraft is created for a subject aircraft, a pointer to the head of that list is saved in the Pair Record. Also in the Pair Record is a field of flags indicating which maneuvers were considered in the determination of the list. If an aircraft goes through master resolution and RAER a second time in the same scan, then it is possible that the same Potential Domino Conflict List may be used. If the resolution advisories being considered for the second conflict are the same or a subset of the resolution advisories considered for the first conflict, then the same list of potential domino conflict aircraft may be used. If the other aircraft in the current pair is on the list of potential domino conflict aircraft, it must be deleted from the list.

13.4.2.4.3 Domino Detection Filter

The remainder of the domino logic consists of performing the detection checks for conflicts requiring resolution advisories between the subject aircraft and each of the aircraft on the Potential Domino Conflict List. The detection checks are performed for each aircraft on the Potential Domino Conflict List or until a conflict is found, for each potential resolution advisory for the subject aircraft. The conflict detection parameters are determined from Table 13-11.

13.4.2.4.3.1 Domino Coarse Detection Filter

To minimize the number of times the Domino Detection Filter is performed, a coarse detection check is performed first. The Domino Coarse Detection Filter determines the need for performing the detailed conflict detection checks at each of the projected points. First, it determines if the two aircraft will be in conflict in the vertical dimension at any time during the domino projection interval. If a conflict in the vertical dimension is not possible during this interval, then the detection checks do not have to be performed for this potential domino conflict aircraft. Otherwise, a coarse check in the horizontal dimension is performed. The horizontal check is not passed if the aircraft are diverging and presently separated by more than the immediate range threshold for a conflict. However, if the potential domino conflict aircraft is receiving a positive horizontal resolution advisory, or the potential resolution advisory to the subject aircraft is a positive horizontal resolution advisory, then the horizontal coarse detection check must be performed from all four of the projected positions. All four checks must fail (indicate a conflict is not possible) for the horizontal check to fail.

The Domino Coarse Detection Filter should not be confused with the Domino Coarse Screen Filter. The Domino Coarse Screen Filter generates a list of aircraft which are in the vicinity of the pair of aircraft in conflict. The Domino Coarse Detection Filter is a way to reduce the computations needed to determine conflicts between aircraft on the Potential Domino Conflict List and a subject aircraft from the conflict pair.

13.4.2.4.3.2 Domino Resolution Advisory Detection Filter

The Domino Resolution Advisory Detection Filter performs only those checks necessary to detect a conflict requiring resolution advisories. Those checks include the tau and immediate range checks in both the horizontal and vertical dimensions. The maneuvering target threat check is not performed.

If the non-mode C option of the domino logic is being performed, then some of the potential domino conflict aircraft may not have mode C data. In a pair including a non-mode C aircraft, the aircraft are assumed to be in conflict in the vertical dimension.

The checks for determining the need for resolution advisories require the computation of tau values and immediate range values. The domino detection filter must compute these values at four points along the projected path of each potential domino conflict aircraft paired with an aircraft from the subject pair. In addition, it is possible to repeat the same calculations twice between the same two aircraft. For example, if a maneuvered aircraft may receive either a turn left or turn right advisory, then the domino logic would repeat the vertical tau and separation calculations against a particular aircraft when checking each horizontal advisory for causing a conflict. The number of computations could be reduced by remembering the outcome of the detection checks between the two aircraft. The data structure for the Potential Domino Conflict List contains fields to remember the outcome of the detection checks.

13.4.3 Tie-Breaking Feature

It is possible for two or more PRA sets to have the same features set after all absolute and relative features are evaluated. In case of a tie, a final tie-breaking feature is used to break the tie. This feature checks for the largest predicted separation after the aircraft respond to the advisories. If a tie still remains, predicted separation shortly after the aircraft begin to respond to the advisories (at QTIME) is checked using the QSEP matrix. This feature is designed to always break ties.

13.5 Pseudocode for Resolution Advisories Evaluation Routine

The high and low level pseudocode for the Resolution Advisories Evaluation Routine is included in this section. Most notation conventions are described in Section 12.4.

Because of the complexity of this logic, the lower level processes are not all simple routines. In some cases, they are themselves high level logical routines that have more than one lower level of subprocess. Tables 13-12 through 13-15 show the process breakdown of RAER.

14. MULTI-SITE RESOLUTION PROCESSING

This section describes intersite ATARS communication and the protocol involved. Communication among sites is required when aircraft are in conflict in regions serviced by more than one ATARS. The protocol involves the messages exchanged and house-keeping actions required to maintain an accurate data base.

When aircraft are in regions covered by adjacent sites, these sites coordinate to assure continuity and non-duplication of resolution service. Two means of coordination are provided in this design. Conflict Tables are exchanged using ground communication lines, where a network connection exists between two sites. This is described in Section 14.1. Elsewhere, the coordination is performed through the aircraft transponders using the Resolution Advisory Register (RAR) required for all ATARS-equipped aircraft. This register also enables coordination between ATARS and BCAS. This coordination is described in Section 14.2. See Reference 9, paragraph 3.3.2.3.1 for the detailed format of the information contained in the RAR.

The ATARS site responsible for a conflict is indicated by the ATSID variable in the Conflict Table Pair Record. This variable may also indicate that BCAS is responsible.

14.1 Conflict Table Exchange Using Ground Lines

The primary means of multi-site coordination uses ground lines, wherever these are installed. This method provides ATARS a complete and current copy of the neighboring site's Conflict Tables so that seam conflicts may be recognized and correctly resolved.

Whenever the Seam Pair Task (Section 10) recognizes a conflict containing an aircraft in a seam, it marks the pair Encounter List entry for delayed resolution. The Request and Process Remote Conflict Tables Task initiates a message through the DABS ground line network to all neighboring sites covering any part of the conflict. The request (see Table 5-3) identifies the pair of aircraft that own-site intends to resolve. This task then becomes dormant until a reply is received. The sector processing executive has the responsibility to terminate the task prematurely when it is time to begin the Master Resolution (Delayed) Task. The neighboring site returns a message to the requesting site containing zero, one, or two Conflict Tables (see Table 5-3). Two tables would be returned if the site had

the two subject aircraft in unconnected conflicts. This routine then merges these Conflict Tables, so that requests on subsequent scans should always receive one Conflict Table in the reply.

When the requesting site receives each reply from a neighboring site, it performs conflict table reply processing. This process updates, adds or deletes Pair Records whose ATSID is or was set to the neighboring site's ID. This routine must be executed even if the reply contains no Conflict Table, as Pair Records may exist in own-site's copy of the Conflict Table. However, if no ground line connection exists, or if the reply is not received by the time the sector processing executive determines processing must continue, this routine is not executed. In this case the latest RAR processing update (Section 5.2) gives information on the neighboring sites' actions.

When a site receives a request for Conflict Tables, that site executes the Incoming Seam Pair Request Processing and Reply Task. This task generates the reply message and sets ATSID in the Pair Record to the requesting site's ID, unless the pair is already being resolved by own-site. It is essential that the reply message be sent as quickly as possible, so that the requesting site may process the reply before it chooses resolution advisories.

The ATCRBS aircraft which appears in an exchanged Conflict Table must be subjected to a correlation procedure by the receiving site when that ATCRBS aircraft first appears. It is necessary to perform this correlation procedure to prevent two adjacent sites from creating separate Conflict Table Entries for the same aircraft.

The site which sends a Conflict Table containing an ATCRBS aircraft will identify that aircraft with a unique ID. The receiving sites need perform the correlation only once. Thereafter, a cross-reference will link that ID to the local State Vector. The ID selected for this purpose must be one that cannot be duplicated by another remote site. For this reason, the ID is constructed by concatenating the local CTS slot number with the ID of the local site.

This cross-reference will contain entries for all ATCRBS aircraft within the local ATARS mask which the local ATARS function currently has in Conflict Tables that are being exchanged. It is identified as CREFX and is entirely unrelated to the CREFA cross-reference used in report processing. Each entry in CREFX consists of an ATCRBS ID (created by either a local or remote ATARS) and a pointer to the State Vector of this aircraft in the

local CTS. For ATCRBS aircraft, the pointer in the State Vector designated ATCREF will be used as a return pointer to this entry in CREFX. Only those ATCRBS aircraft which are in seam Conflict Tables will have an entry in CREFX and have a non-null value for ATCREF.

The ATCRBS correlation procedure consists of a proximity test plus ATCRBS code check. An ATCRBS "report" is always transmitted with an ATCRBS aircraft ID in a Conflict Table. This report consists only of the current predicted range, azimuth, and altitude coordinates and the ATCRBS code. In the ATCRBS correlation, the remote range and azimuth are converted to local coordinates. The correlation procedure consists of using the X/EX-list in much the same way as in coarse screening. The proper location of the ATCRBS report in the X/EX-list is found. A search along the X/EX-list in both directions to x limits is made. All aircraft encountered are tested against y and z limits and against the ATCRBS code. The correlation procedure is successful if one and only one ATCRBS aircraft is found satisfying the requirements.

Correlation should be attempted every scan until a successful correlation occurs. Hence, the failure to correlate on the first appearance of a new ATCRBS aircraft is not fatal. An entry in REMA is created and used until a successful correlation occurs.

Two other new data structures, besides CREFX, are used to provide cross-referencing during the processing of exchanged Conflict Tables. These are the remote DABS (REMD) and remote ATCRBS (REMA) lists. A single entry on one of these lists applies to a single aircraft. The entry is a subset of the aircraft State Vector. An entry on these lists is accessed either directly with a pointer or through a cross-reference with an aircraft ID (either a DABS code or the same type of ATCRBS ID used with CREFX).

It may happen that a remote ATARS will pass a seam Conflict Table that includes one or more aircraft which are not within the local data base. The local ATARS must retain these aircraft in the Conflict Tables as place-keepers so that, when the local ATARS is required to perform conflict resolution on an aircraft in this Conflict Table which is in the local data base, an accurate Conflict Table exists. The local ATARS is not required to process these remote aircraft in any other way. Hence, the entries in REMD and REMA serve essentially as abbreviated State Vectors.

The REMFLG in the Conflict Table entry registers the current remote status of the aircraft to which that entry refers. If REMFLG is set, the ACID field in that Conflict Table entry points to an entry in REMD or REMA instead of to a State Vector. REMFLG is not transmitted in the Conflict Table message because each ATARS must determine for itself if a particular aircraft is remote.

The local ATARS determines the value to be used for NAC in the Conflict Table head of a received Conflict Table by counting the number of Conflict Table entries. This field is not transmitted in the Conflict Table Exchange Message.

14.2 Conflict Table Exchange Using RAR

Since all ATARS-equipped aircraft have a RAR, the information contained therein is always used to update and exchange conflict information. This data exchange is primary for purposes of coordination with BCAS, and for confirming that own ATARS resolution advisories were received (see Section 5.2 for both of these); and for determining the current multi-site seam status of the aircraft in geographical processing (see Section 6.2.2). When ground communication lines are installed and operating, the RAR exchange is secondary for multi-site ATARS. When no ground lines are available, the RAR becomes the primary method of coordination.

All resolution advisories sent to an aircraft are stored in the RAR (unless rejected for incompatibility). The RAR is read every scan by every ATARS site providing service to the aircraft. In this way, one site can learn of another site's action affecting aircraft in the seam. Although the conflict information exchanged this way (see Table 5-2) is less detailed than that exchanged over ground lines, it contains sufficient information to ensure selection of compatible advisories.

Every RAR column indicates the system responsible for its resolution advisories. Normally, when adjacent sites are connected, the ATARS site originally resolving a conflict continues the resolution to the conflict end. This is true even when the pair flies into a seam area where another site would normally have higher priority. However, when an aircraft leaves a site's service area, that site must release it for pairs involving this aircraft. This action is called a "handoff" in this document but is unrelated to ATC handoffs. The site releasing it sends a message to any connected neighboring sites indicated in the aircraft GEOG variable. This action gives the

neighboring sites an opportunity to immediately assume responsibility for the pair. If the ground line is not available, a neighboring site takes responsibility using the rules listed in Section 10.

14.3 Pseudocode for Multi-site Resolution Processing

The pseudocode for Multi-site Resolution Processing contains two tasks: the Request and Process Remote Conflict Tables Task, and the Incoming Seam Pair Request Processing and Reply Task. These two tasks are concerned with the exchange and updating of information in the Conflict Table data structure. This pseudocode does not provide the full details of Pair Record creation, deletion or updating. These should conform to the treatment of Conflict Tables elsewhere in the document, except where otherwise specified.

15. PAIR AND TRACK REMOVAL PROCESSING

The Resolution Deletion Task and the Conflict Pair Cleanup Task ensure that each conflict resolved by the local site is closed out in the proper manner when the conflict is over and that conflict data stored in the Pair Records is deleted when it is no longer needed. The State Vector Deletion Task removes aircraft from the Central Track Store when they leave the ATARS/Domino Surveillance Area or when they are no longer being adequately tracked.

15.1 Resolution Deletion Task

The Resolution Deletion Task examines the Encounter List for conflict pairs no longer requiring resolution advisories. For each such pair, this task calls the Conflict Closeout Routine to determine whether the Pair Record can be deleted. If so, the Pair Record Deletion Routine is called. If not, the PWISF flag is set in the Pair Record to indicate that the pair has been processed on the current scan.

The Conflict Closeout Routine checks for two basic conditions: (1) an aircraft has just flown out of the coverage area of the local site, and or (2) the local site has assumed responsibility for the pair, but is no longer calling for resolution advisories. When an aircraft is discovered to have flown out of coverage of the local site, all resolution advisory information pertaining to that aircraft can be cleared out of the Conflict Table; this may mean that a Pair Record involving that aircraft can be deleted immediately. For a local-responsibility conflict where resolution advisories are no longer needed, the Conflict Closeout Routine will normally place null resolution advisories in the Conflict Table. In some exceptional cases (e.g., positive advisories have not been up long enough), however, the Pair Record will be left unchanged as long as necessary. Once the aircraft have received null advisories for a conflict, the Conflict Closeout Routine will permit the Pair Record to be deleted. In instances where initial resolution advisories have not yet been selected for a conflict but the detection logic is not calling for resolution on the current scan, the Conflict Closeout Routine implements part of the two-out-of-three logic by updating POSCMD and deleting the Pair Record if appropriate.

The job of deleting a Pair Record is always performed by the Pair Record Deletion Routine. This routine is called by the Resolution Deletion and Conflict Pair Cleanup Tasks, as well as by the RAR Processing Task, the Request and Process Remote Conflict Tables Task, and the Backup Mode Initiation Process.

When a Pair Record is deleted, the Conflict Table entry for each aircraft may be simplified or deleted. It is possible at this point for a multi-aircraft Conflict Table to split into two separate Conflict Tables. It then becomes necessary to determine which aircraft belong in each of the resultant tables. This is accomplished by examining the remaining Pair Records and Conflict Table entries. This process is described conceptually in the pseudocode as the creation of three new lists (A, B, and C - lists). However, the same effect can be achieved by the manipulation of pointers, rather than by the actual creation of separate lists of aircraft and conflict pairs.

15.2 Conflict Pair Cleanup Task

The Conflict Pair Cleanup Task performs a function equivalent to the Resolution Deletion Task. The Conflict Closeout Routine and the Pair Record Deletion Routine are the primary routines called by this task. The Conflict Pair Cleanup Task serves primarily as a backup to the Resolution Deletion Task to ensure that no conflict pairs are overlooked and fail to be deleted when the data is no longer needed. This task might be needed, for instance, if a pair for which own site is responsible unexpectedly failed to pass through the coarse screen filter. Unlike the Resolution Deletion Task, the Conflict Pair Cleanup Task searches through the Pair Records for the current ATARS sector, looking for pairs which have not been processed on the current scan.

15.3 State Vector Deletion Task

This task processes aircraft on the Deletion List (not to be confused with "resolution deletion" entries on the Encounter List) and removes each aircraft State Vector from the Central Track Store if appropriate. An aircraft may be put on the Deletion List in three ways:

1. By the Track Update Process if DABS has lost surveillance contact with the aircraft.
2. By the Track Update Process if missed reports have caused the ATARS track firmness to drop below the level needed to qualify for ATARS service.
3. By the Report Processing Task if the track is seen to have left the ATARS/Domino Surveillance Area.

If the aircraft is still contained in a Conflict Table, a REMA or REMD entry is created at the time the State Vector is

deleted. If ATARS has some unfinished business with the aircraft, such as a null advisory to be sent, State Vector deletion is delayed.

15.4 Pseudocode for Pair and Track Removal Processing

The pseudocode for pair and track removal is presented in this section. It should be noted that the Resolution Deletion Task and the Conflict Pair Cleanup Task call the same set of routines, which are presented once, following the Resolution Deletion Task. Also note that in the Conflict Closeout Routine, pointer (PTR) variables are used to indicate variable GROUP names; this convention does not adhere strictly to the established rules for pseudocode.

16. MESSAGE UPLINK PROCESSING

This section discusses the construction of the uplink messages to equipped aircraft. These messages are defined in the ATARS National Aviation Standard (Reference 9). All the messages discussed in this section are sent in the MA field of a DABS Comm-A message. Reference 9 provides complete details of these messages, their signal formats, and their coding.

16.1 Classes of ATARS Service

Reference 9 currently defines three classes of ATARS Service, denoted as Class 0, Class 1, and Class 2. This document contains the logic to service only these classes, although more may be defined in the future. The classes represent alternative levels of information. Messages from one of these classes are sent to an aircraft according to its airborne processing capabilities. The message sets are designed to minimize the processing required by the simplest user, and thus minimize his avionics cost; and to minimize the ATARS message load on the DABS channel by not sending certain information to those aircraft not equipped to process it.

Certain message types, namely the ATARS Resolution and the ATCRBS Track Block Messages, are common to all three classes of Service. These are described in the section for Class 0 service. Certain other types are also common to Classes 1 and 2. These are described in the section for Class 1 Service. A summary of all message types appears in Reference 9 and is repeated herein as Table 16-1.

16.1.1 Class 0 Service

Class 0 Service is intended for an aircraft with simple ATARS avionics. The avionics is assumed not to store traffic advisory data in a "track file," as described below for higher classes of service. The avionics may only display position data for one traffic advisory at a time, or it may be capable of displaying several traffic advisories. To allow for this limited capability, traffic advisories are ordered in decreasing order of "importance" so that the pilot will be shown the most urgent one(s). The following sections define the messages for Class 0 Service.

16.1.1.1 ATARS Resolution Message

This message is the same for all classes of service. It contains a 14-bit COL field, which is the column to be written

TABLE 16-1
MA SUBFIELD STRUCTURE OF ATARS MESSAGES

ATARS MESSAGE NAME	CLASS OF ATARS SERVICE	SUBFIELD	STRUCTURE OF MA
Bit33-----Bit40 Bit 41-----Bit88			
(ADS1:4) (ADS2:4)			
ATARS Resolution	0,1,2	-3 -0	(COL:14) (TRA:19) (**:12) (SIT:3)
Not Assigned	-	-3 -1-15	-
Six Advisories	0	-1 -0	(**:12) (**:12) (SIX:6) (SIX:6) (SIX:6) (SIX:6)
Three Advisories	0	-1 -1	(**:18) (**:18) (**:12)
Not Assigned	-	-1 -2	-
ATCRBS Track Block	0,1,2	-1 -3	Note: Defined in Ref. 11: 3.3.2.3.2 and is sent only to BCAS equipped aircraft.
Not Assigned	-1	-1 -4-6	-
Auxiliary Advisories	1,2	-1 -7	When RST=0 (TER:8) (OBT:13) (RST:1) (OBT:13) (OBT:13) When RST=1 (TER:8) (OBT:13) (RST:1) (RTD:26)
Own Plus Altitude Echo	2	-1 -8	(ODS:24) (AEC:24)
Own Plus Proximity	2	-1 -9	(ODS:24) (PDT:24)
Start/End Encounter	2	-1 -10	(PDT:24) (SED:24)
Dual Proximity	1,2	-1 -11	(PDT:24) (PDT:24)
Proximity Plus Altitude Echo	1,2	-1 -12	(PDT:24) (AEC:24)
Start Threat	2	-1 -13	(ODS:24) (STD:24)
Threat	1,2	-1 -14	(PDT:24) (TRD:24)
Not Assigned	-	-1 -15	-
(**:12) can be either (TPA:12), (TEA:12), (OBA:12) OR (RAA:12), or a Null Advisory (**:18) can be either (TPE:18), (APE:18), (TAE:18), (OAE:18), OR (RAE:18), or a Null Advisory			

Note: (XXX:N) denotes a subfield designated "XXX" which is assigned N bits.

into the aircraft RAR column designated by the SIT field. The COL field represents the composite of all resolutions the site is sending the aircraft for all conflict pairs. The site repeats the message each scan during the conflict, and sends this message again with COL containing all zeros, once at the end of the conflict to remove its advisories from the RAR. SIT corresponds to the ID of the site originating the advisories. It is normally set to own-ID. In the backup-master mode, it may contain the failed site's ID. When performing remote uplink, it contains the requesting site's ID.

This message contains the TRA subfield which describes the threat or proximate aircraft causing the resolution advisory. In the case of a multi-aircraft encounter, the most critical threat is used. A resolution advisory should always be caused by an aircraft whose Encounter List entry is a Threat type. However, on the scan when the final (zero) COL field is sent, the only traffic remaining may have entries with Proximity type.

The resolution message also contains a 12-bit subfield. This may contain another threat or proximity advisory, or a terrain, airspace, or obstacle advisory.

16.1.1.2 ATCRBS Track Block Message

This message is sent only to BCAS-equipped aircraft. Its generation (Section 8.1) is dependent upon BCAS logic, and is independent of any ATARS traffic and/or resolution advisories to BCAS for the same ATCRBS traffic. Up to eight such messages may be sent to each BCAS aircraft, depending upon the number of qualifying ATCRBS tracks. The message contains a SIT field as in the ATARS Resolution Message, and a track number to aid BCAS in associating messages with the same track on subsequent scans. The track data contains range, range rate, altitude, altitude rate, and bearing. ATARS tracked data is predicted ahead one scan to the time of transmission of the message.

16.1.1.3 Three Advisories Message

If no ATARS Resolution Message is constructed, this message is used to send up to three advisories. The first two advisories are contained in 18-bit subfields, and the third in a 12-bit subfield as described above for the ATARS Resolution Message. The 18-bit subfields may contain any of the following: a threat or proximity advisory, which is like that of the 12-bit subfield

with additional data for range and fine altitude; terrain, airspace or obstacle advisories containing the same data as for the 12-bit subfield; or an altitude echo. If there are at least two traffic advisories, these will use the 18-bit subfields and any altitude echo in the PWILST will not be sent. If there are less than two traffic advisories, an altitude echo will always be sent in an 18-bit subfield, unless sending the altitude echo creates a need for an extra message.

16.1.1.4 Six Advisories Message

If more advisories remain to be sent after either the ATARS Resolution or the Three Advisories Messages are constructed, up to six additional advisories may be sent in this message. These are limited to fewer bits than those preceding but would correspond to less important advisories. Any remaining advisories after these six would not be sent to the aircraft this scan.

The first two advisories use the same 12-bit subfield described above. The remaining four advisories are contained in 6-bit subfields. These subfields may only contain proximity or threat advisories. Thus, if the proximity and threat advisories on the PWILST have not all been sent before reaching the 6-bit subfields, any terrain, airspace, or obstacle advisories will not be sent. This only happens when there are at least five traffic advisories, or at least four traffic advisories and a resolution advisory.

16.1.2 Class 1 Service

Class 1 Service will support a graphic display and is intended for aircraft capable of displaying larger quantities of data than the Class 0 aircraft. In most cases, more messages will be sent to such aircraft to uplink the same number of advisories. The ATARS Resolution Message and the ATCRBS Track Block Message are as described in Sections 16.1.1.1 and 16.1.1.2. However, any traffic advisory data contained in the ATARS Resolution Message is repeated using the messages below.

16.1.2.1 Dual Proximity Message

This message contains position data for two proximity advisories. Each advisory is sent in a Position Data Subfield, which contains clock and fine bearing, altitude zone and fine altitude, range, the heading of the traffic, and the control state and ATARS equipage of the traffic. A first-time transmitted bit is sent to denote new traffic.

16.1.2.2 Threat Message

This message contains one threat advisory. It consists of a Position Data Subfield as above, plus a Threat Data Subfield containing an altitude extension, fine heading, horizontal miss distance, turn type, vertical speed of the threat, and an indication as to whether the threat is causing a resolution advisory to be sent to own aircraft.

16.1.2.3 Proximity Plus Altitude Echo Message

This message combines one proximity advisory with altitude echo data. It contains the last (i.e. least important) proximity advisory. If no single proximity advisory remains after all Dual Proximity Messages are built (if any), and an altitude echo is required, a null Position Data Subfield will be inserted to complete this message.

16.1.2.4 Auxiliary Advisories Message

This message contains terrain, obstacle, and airspace advisories. Its format contains a terrain warning (if needed), an obstacle advisory (if needed), and either an airspace advisory or up to two additional obstacle advisories. Both its obstacle and airspace advisories include specific identification data not provided in the Class 0 formats. A first-time transmitted bit is sent to denote each new advisory.

16.1.3 Class 2 Service

Class 2 Service is intended for aircraft with sophisticated avionics capable of tracking traffic from scan to scan. Class 2 messages include the entire set of Class 1 messages plus additional types intended to aid such avionics. These additional messages are described below.

16.1.3.1 Start/End Encounter Message

This message helps the avionics start a track by assigning a track number to the traffic. The message contains a Position Data Subfield and a Start/End Subfield. The latter indicates whether to begin or end the track, assigns the track number, and contains the groundspeed, climb performance, and abbreviated identification data for the traffic. Up to eight unique track numbers may be assigned to tracks for an aircraft's traffic advisories. The End Encounter Message is normally sent at the conclusion of traffic advisory status. However, if more than eight tracks qualify simultaneously, ATARS sends a Start

Encounter Message when a new track is chosen to replace an old one with the same number, and this implies the end of the old track.

16.1.3.2 Own Plus Proximity Message

This message combines a single proximity advisory with own-aircraft data. The own-aircraft data allows the avionics to more accurately relate advisory data to own aircraft's heading, speed and turn rate. It also confirms the class of ATARS service in use. A bit indicates the initiation or handoff of ATARS service, to indicate to the avionics possible track number discontinuities if sensors change ATARS responsibility during an encounter.

16.1.3.3 Own Plus Altitude Echo Message

This message combines own-aircraft data with altitude echo data and is uplinked when both of these types are required.

16.1.3.4 Start Threat Message

This message combines own-aircraft data with a Start Threat Data Subfield. The latter is the same as a Start Encounter Message, except the Start/End bit is replaced by a bit indicating whether the threat is a new track or is an upgrade of an existing proximity advisory to a threat.

16.2 Data Link Message Construction Task

The Data Link Message Construction (DLMC) Task assembles messages for uplink to each equipped aircraft in the ATARS service area. The following sections describe the functions performed by this task.

16.2.1 Ranking PWILST Entries

The uplink messages are eventually constructed from the entries on the aircraft's PWILST. These entries are created in the order that pairs on the Encounter List are processed. However, the desired order of their uplink is determined by factors independent of this original ordering. The ranking procedure reorders the list, enabling the subsequent procedures to travel through the list and assemble messages in the desired order.

Assuming all types are present, the Entry Ranking Process produces the ordering of entries shown in Table 16-2. The groups numbered 2, 4, and 9 are selected using only the TYPE of the entry. For all TA_PROX or TA_THREAT entries, the Entry Ranking Process calculates the current value of each entry's RANKTYP field according to the criteria shown in the "Meaning" column of Table 16-2.

Within each group containing traffic advisory entries, the entries are ordered according to additional rank data. The formats of these fields are also shown in Table 16-2. The Traffic Advisory Task (Section 9) computes the "tau" and "weighted range" fields each scan, using data from the encounter list entry. The DLMT Task assigns the RANKTYP. Both tau and weighted range are stored in two's complement form. These fields are concatenated and then interpreted as a single unsigned integer. This interpretation causes entries with the smallest positive values of tau and range (i.e. shortest tau and closest range) to receive the highest ranking within each group. Both tasks update their respective data each scan that the entry is refreshed. Within groups 1 and 3 (separately), the ranking procedure orders entries by tau and weighted range. Within groups 5 through 8 (separately), this procedure orders proximities with mode C altitude reports ahead of non-mode C proximities, and within each group, orders entries by weighted range. Within groups 2, 4, and 10, the order is immaterial. Group 9 can have only one entry. This ranking orders the entries by importance, and avoids problems in class 2 message construction, in which advisories in a Start/End Encounter Message use a full message, while proximities may be paired together or paired with ALEC or Own-aircraft data. The only adverse impact of this ranking for Class 0 or 1 users is minor: a new proximity advisory may precede another for closer traffic on one scan.

There are no OWN entries on the PWILST, as all the logic to generate Own-aircraft data subfields is handled locally within the DLMT Task. Also, group 10 entries (END Threat or Prox) are only kept for class 2 ATARS users.

16.2.2 Altitude Echo

Altitude Echo (ALEC) PWILST entries are created for any of several reasons:

TABLE 16-2
RANKING ENTRIES ON THE PWILST

<u>GROUP</u>	<u>ENTRY TYPE</u>	<u>RANKTYP FIELD</u>	<u>MEANING OF RANKTYP FIELD</u>
1.	TA_THREAT	1100	SVECT.CTPTR non-null
2.	ATCRBS_TB	- -	
3.	TA_THREAT	1000	SVECT.CTPTR null and TA_THREAT.END not set
4.	TERRAIN AIRSPACE, OBSTACLE	- -	
5.	TA_PROX	0101	SVECT.MCFLG set and TA_PROX.OLD_TYPE = "none"
6.	TA_PROX	0100	SVECT.MCFLG not set and TA_PROX.OLD_TYPE = "none"
7.	TA_PROX	0011	SVECT.MCFLG set and TA_PROX.OLD_TYPE not "none" and TA_PROX.END not set
8.	TA_PROX	0010	SVECT.MCFLG not set and TA_PROX.OLD_TYPE not "none" and TA_PROX.END not set
9.	ALEC	- -	
10.	TA_PROX, TA_THREAT	0000	END set

TABLE 16-2
(Concluded)

-Tau Field

Set to zero for TA_PROX types.
For TA_THREAT types, two's complement of "Tau" (stored by
Traffic Advisory Task)

-Weighted Range Field

Two's complement of weighted range (stored by Traffic Advisory
Task)

Note: The -Tau and -Weighted Range fields are concatenated and
interpreted as a single binary unsigned integer in the ranking
process.

- a. When a pilot sends an ALEC request (received in a DABS surveillance report), the Report Processing Task (Section 4.4) creates an ALEC entry.
- b. When an equipped aircraft enters ATARS service, the DLMC Task notes that ALECT in the State Vector is uninitialized, and creates an ALEC entry.
- c. When sufficient time has elapsed since ALECT, the time of the last ALEC message to the aircraft, the DLMC Task creates an ALEC entry.
- d. When an ALEC uplink fails, the uplink delivery notice process in Non-surveillance Message Processing Task (Section 5.1) resets ALECT to an uninitialized value to force an immediate retry as in b. above.

As stated in Section 16.1, in periods of heavy traffic, the low priority assigned ALEC may cause this message not to be assigned a field if the user is ATARS Class 0, or to not be delivered if many uplinks are scheduled, for other user classes. In all cases, ALEC will be retried as soon as traffic becomes light enough.

16.2.3 Construction of Uplink Messages

After ordering PWILST entries and assigning track numbers, the DLMC Task constructs as many uplink message MA fields (see References 9, 10) as required to send ATARS advisories to each equipped aircraft. The pseudocode specifies the fields that are to be built within each message. The detailed coding of these fields is in Reference 9. For Class 1 and 2 users, every 48-bit MA field contains two 24-bit fields, as shown in Table 16-1. The pseudocode uses a local variable SUBFIELDNO to indicate whether the first or second of these in an uplink message is next to be filled. The ADS code is added to indicate the type of message and define the subfields that follow. All completed messages are sent as uplinks, as specified in Section 3.2.

16.2.4 Deleting PWILST Entries

The various types of PWILST entries are removed in different ways. Some types are sent only once; others are dropped when not refreshed; and some need an end message uplinked.

TA types (THREAT and PROX) contain an END item which is set by uplink delivery notice processing after they are successfully delivered. If an entry again qualifies for TA status, the Traffic Advisory Task resets END. If not, the DLMC Task Entry Ranking Process deletes these entries if the user is Class 0 or 1, as an end message is not sent to these users. If the user is Class 2, the DLMC Task builds an End Encounter Message and then immediately deletes the PWILST entry.

An ALEC entry is deleted by the DLMC Task immediately after the message is built.

Terrain, Airspace, and Obstacle types also contain an END item which is set by uplink delivery notice processing after successful delivery. The T/A/O Task resets END each scan that the alert continues. When the alert ends, END is not reset and the DLMC Task Entry Ranking Process deletes the entry.

ATCRBS Track Blocks likewise contain END. A single attempt to send an End Track Block is made for these types. The DLMC Task sets END when the ATCRBS Track Block Message is constructed. If the Traffic Advisory Task does not reset END on the next scan, the DLMC Task sends an End Track Block and deletes the PWILST entry.

16.3 Pseudocode for Message Uplink Processing

The following comments will clarify the implementation of the Data Link Message Construction Task. The pseudocode repeatedly refers to PWILST entries of a particular TYPE. While TYPE is not a field in the entry, the definitions of PWILST entries in Section 3 pseudocode identify the TYPE for each.

The Entry Ranking Process makes several passes through an aircraft's PWILST. These passes include the RANKTYP assignment and reordering discussed in Section 16.2.1, and the assignment of track numbers. It is suggested that temporary lists be kept of unused track numbers and of ATCRBS Track Block track numbers.

The various message generation processes primarily look down an aircraft's PWILST to find the next entry which has not been marked SENT. An exception is the Auxiliary Advisories Message Generation Process, which builds the Auxiliary Advisories Message from all T/A/O entries on the PWILST and marks them all SENT.

As uplink messages are built, the pseudocode assigns an ADS code. These are shown as the appropriate ATARS Message name.

See Table 16-1 for the corresponding numerical values. The priority bit included with each message is not uplinked to the aircraft, and thus is not contained in the formats shown in Table 16-1. This bit is used by the DABS sensor in its message scheduling (Reference 1). The phrase "move to uplink buffer" means "build the complete message format as shown in References 1 and 8". If SVECT.REMRAR is set to a positive value, the uplink messages should be routed to the remote sensor indicated. In all other cases, the local sensor performs the uplink.

As each message is moved to the uplink buffer, a copy is linked to a list kept for the aircraft. This list, which is discarded and created anew each scan, is pointed to by SVECT.UPMES.

17. FAILURE MODE OPERATION

17.1 Failure Provisions in ATARS Design

Protection against numerous types of failures is incorporated in the ATARS system design. Specific features are provided to cope with the following ATARS-specific failures:

1. Failure to receive a target report from the local sensor
2. False altitude or track association in target report from local sensor
3. Failure to deliver traffic or resolution advisory by local sensor
4. ATARS selects a resolution advisory which is incompatible with an aircraft's existing resolution advisories
5. Failure of a ground communication channel between sensors
6. Where a ground communication channel is not provided, or has failed, ATARS selects resolution advisories, not knowing the pair of aircraft is already being resolved by another ATARS site
7. Failure of the DABS sensor at a single site
8. Failure of the ATARS function at a single site
9. Catastrophic failure of an ATC facility

Logic for items 7 and 8 is contained in this section. The features which accommodate the other items are found in other sections of this document. All the capabilities are discussed here to summarize the robust nature of the overall design.

17.1.1 Missing Target Report

If the local sensor misses a target report on an aircraft, it requests a report from an adjacent sensor. ATARS performs coordinate and time conversion for the remote report and uses it to update the track for the aircraft. If the aircraft is ATARS equipped, ATARS requests a RAR report from the remote sensor. Even if that sensor was not previously reading the aircraft's RAR, the remote sensor may do so.

When a sensor detects an aircraft passing into its antenna's zenith cone ("cone of silence"), it requests an adjacent sensor to provide target reports continuously until told to stop. In a like manner, ATARS requests RAR reports from the adjacent sensor, for an equipped aircraft, to be provided until told to stop. The adjacent sensor "borrows" the original site's ATARS ID during this condition.

If no target report is obtained from any sensor (e.g., no adjacent sensor covered the aircraft's location or no ground communication channel is operating), ATARS coasts the track using its last estimates of position and velocity. Full conflict detection continues. If no report is received by a predetermined time, ATARS drops the track.

If a position report is received with altitude missing, the altitude estimate is coasted. If a target report is received but RAR data is missing, ATARS assumes the last known RAR contents are unchanged, rather than assuming an empty RAR.

17.1.2 Target Report Contains False Altitude or Track Association

ATARS maintains tracks on aircraft in its service area which are independent of DABS surveillance tracks. Since the requirements of a collision avoidance system differ from a surveillance system, ATARS uses its own criteria for establishing or dropping tracks.

ATARS performs a reasonability check on each altitude report. If unreasonable, the altitude report is ignored. If a falsely decoded altitude is sufficiently reasonable to be accepted, it is smoothed by the tracker and thus is unlikely to seriously affect ATARS service.

17.1.3 Sensor Fails to Deliver Traffic or Resolution Advisory

Although the DABS data link is very reliable, the sensor may occasionally fail to deliver traffic or resolution advisories. When a target report was received, but part or all of the ATARS messages were not delivered during the beam dwell, ATARS has good reason to believe that the aircraft is still visible to the sensor. ATARS simply computes updated advisories for the next scan. In the meantime, the avionics retains the existing advisories until they are updated, or until a time out several scans in length has expired. When an ATARS uplink message was attempted and not even a target report was successfully achieved by the local sensor, ATARS immediately attempts to deliver its

messages through one (and only one) adjacent connected sensor. The adjacent sensor borrows the local ATARS ID, regardless of whether or not its own ATARS is providing service to the aircraft. The DABS multi-link protocol may not be used for ATARS uplink messages.

17.1.4 ATARS Selects Incompatible Resolution Advisory

ATARS resolution logic always selects new resolution advisories compatible with an aircraft's existing resolution advisories. However, if an existing advisory is not known to the ground, an incompatible (i.e., contradictory) sense advisory could be uplinked. This could happen if a BCAS outside ATARS coverage (called a "pop-up" threat) initiated resolution with the subject aircraft since the last RAR downlink; or if another ATARS site, unconnected by a ground communications link, resolved another conflict since the last RAR downlink.

Any incompatible advisory is rejected by the ATARS avionics. The RAR performs a compatibility check for every uplinked advisory. If multiple advisories are being uplinked, all compatible advisories will be accepted even if others are incompatible and rejected. ATARS reads down a copy of the RAR contents as they existed at the time the RAR was accessed. ATARS duplicates the avionics' compatibility logic to immediately determine whether each of its uplink advisories will be accepted. For any which are found incompatible, new advisories are recomputed for delivery the next scan, taking account of the updated copy of the RAR contents. This logic is described in Section 5.2.

17.1.5 Failure of Ground Communications Channel

A ground communications channel between sensors is not a critical element for ATARS operation. Where a network of more than two DABS sensors exists, the loss of a ground channel prompts DABS network management to establish alternate message paths. Whenever this succeeds, the ground channel failure is transparent to ATARS.

When ATARS becomes unconnected to a neighbor, some degradation of service will occur, since remote reports, cone of silence coverage, and remote uplink become unavailable. However, the majority of service, including multi-site coordination of conflict resolution, continues unaffected. The RAR is used as the coordinating device for all resolution, and responsibility is unchanged.

17.1.6 Resolution Duplicating That Provided by Another Site

Whenever a ground communication channel is available, positive coordination between sites assumes that only one site at a time issues resolution advisories to a particular pair of aircraft. However, when no channel is provided, or when the channel has failed, such duplicate service may be attempted in certain situations. This primarily happens when a DABS-ATCR^S pair moves into the low altitude part of an ATARS seam; or for unusual situations such as when a DABS-DABS pair flies into an ATARS seam and site responsibility changes just before the conflict begins, and one site has been unable to read down the ATARS site ID bits for at least one scan since they changed. The latter situation is a compound event of low probability.

The principal case is handled by having the site designated "lower priority" evaluate the other site's advisory to the DABS aircraft. If this appears adequate, the site yields responsibility to the higher priority site. In any event, the compatibility logic within the RAR prevents contradictory advisories from being posted.

17.1.7 Failure of the DABS Sensor

The DABS sensor is complex and may fail in a variety of ways, many of which are beyond the scope of this document. Any failure which causes the local ATARS function to fail is treated in the next Section.

If only the surveillance function or RF channel fails, so that ATARS continues to operate, data from remote sensors may be used as described in Section 17.1.1. In this case, ATARS attempts to provide service in its usual area, but is limited to servicing those aircraft seen by adjacent connected sensors. It is the responsibility of the local DABS to request the remote surveillance.

17.1.8 Failure of ATARS Function

Any network of neighboring DABS sensors may take advantage of overlapping DABS coverage for the purpose of allocating replacement coverage for a failed ATARS site. Section 17.3 discusses the means for recognition of a failed ATARS and the action to be taken.

17.1.9 Failure of the ATC Facility

ATARS normally serves controlled aircraft only as a backup to ATC. When aircraft come into conflict in sufficiently hazardous

situations, ATARS issues traffic and resolution advisories. This action is performed routinely, and in the event of a catastrophic ATC failure, ATARS continues to provide full service.

17.2 Function Status Processing

Each DABS sensor contains a performance monitoring function. Once per scan, the sensor sends sensor status and ATARS Status Messages to all adjacent sensors. ATARS is only interested in the status ("operational" or "failed") of the ATARS function of each of its neighbors. Whenever such Status Messages are received, the Non-surveillance Message Processing Task (Section 5.1) calls the Remote Function Status Routine. This routine examines all remote ATARS Status Messages which have been queued since the last execution of the routine. The routine maintains a function failure table indicating the status of each remote ATARS. However, the logic only accommodates a single remote ATARS failure.

17.3 ATARS Backup Mode

Upon recognizing the first such failure, the Backup Mode Initiation Process is performed. This process replaces the ATARS service map with the backup service map corresponding to the failed ATARS. Tables are stored to indicate the appropriate service map to use after the failure of any neighboring site. The table MAPTBL (i) contains the list of map vertices corresponding to site (i) failing. The value i = 0 is used for the normal mode of operation. Similarly, the table MASTRTBL(i) contains bits to indicate whether or not own-site becomes the master site upon the failure of site (i). If Own-site becomes Master for more than one neighbor's failure (but always one at a time), another table CTRTBL(i) stores the map vertices for the center zone areas. ATARS does not assume a remote ATARS failure when a communication line fails. A separate register keeps track of currently connected sites. This is used in various places in the logic.

When an "operational status" indication is received in a message from a previously failed ATARS, the Backup Mode Termination Process is executed. This routine merely reinstates the normal service area, and resets the Backup and Master flags. It is not necessary to send Conflict Tables to the recovered site, since that site should be able to immediately read down aircraft RAR's, and may request Conflict Tables from its neighbors over ground lines. When the (smaller) normal service map is reinstated, aircraft outside this map will be dropped from ATARS service in the normal way, just as if they had flown out of the service zone.

17.3.1 Backup ATARS Service Areas

In a region having several DABS sensors located within reasonable proximity, some flexibility may exist in drawing the ATARS map boundaries. The choice of boundaries will take into account geographical coverage, terrain features and the expected traffic load for the sensors. Upon the failure of one ATARS site, other sensors with overlapping coverage may be capable of replacing the failed ATARS. If the failed site was serving a large load of traffic, no single neighbor may have sufficient capacity to absorb it all. Therefore, a better strategy, where geographic coverage and terrain features permit, is to divide the failed site's service area among several neighbors.

An example of this operation is depicted in Figure 17-1. Here, when the site with ID 0010 fails, its two neighbors each expand their coverage and share the failed site's area. The two surviving sites' maps should provide an overlap (seam) of the usual width. In this case, no "master" site or "center" zone (see below) is required. Both surviving sites operate normally, and treat newly acquired aircraft in their expanded service areas in the same manner as any aircraft which has just entered the normal service area. Any of these aircraft having RAR entries created by the failed site will soon have them released by the avionics time out.

The surviving sites may not be connected with ground communications lines. In this case, all coordination is performed through the transponders using the RAR features, as explained in Section 14.2.

17.3.2 Master Site

In certain configurations of ATARS sites, the simple procedure described above cannot be used. Since only four distinct ATARS ID's are assigned, the failure of an ATARS may cause two sites assigned the same ID to become adjacent, if the most desirable backup service map were implemented. Since the multi-site protocol does not permit this condition, several alternatives are available. Using another neighbor to cover the failed area may be feasible, but geographic considerations may prohibit this choice. Leaving a coverage gap without ATARS is very undesirable. The solution implemented in this design is to designate one of the surviving sites as the "Master" site. This should be the site with the best geographical coverage of the part of the failed area that separates the two sites having the same ATARS ID. The master site then continues to serve its own

A) COVERAGE WITH ALL 3 SITES OPERATING

B) COVERAGE WHEN SITE 0010 FAILS

**FIGURE 17-1
EXAMPLE OF AREA WHERE CENTER ZONE NOT USED
FOR BACKUP COVERAGE**

ATARS area using its own ID, and also serves a small "center" zone within the failed site's area, borrowing the failed site's ATARS ID to send to aircraft in this area. This is illustrated in Figure 17-2. The center zone should be made small, so all sites may use their own ID in as large an area as possible, but sites with like ATARS ID's must be separated by more than the usual seam width.

The master site performs an extra masking (in this backup mode) to decide which of the aircraft in its expanded coverage are in the center zone and thus are to receive the failed site's ID. The master site still uses its own sensor to service both of its areas, sending different ATARS ID's to aircraft according to their location. The center zone is mapped to have the usual overlap (seam) with all of its neighboring sites except the master site. No overlap is provided between Master's own area and its center zone. The master ATARS keeps aircraft in both of its areas in the same data base, and is able to treat the boundary between its two areas as "soft". This means that if an aircraft receiving resolution crosses this boundary, the master site may change the site ID sent to that aircraft, while continuing to send the other ID to the other aircraft until it too crosses the boundary.

17.4 Pseudocode for Failure Mode Operation

The pseudocode follows. The Remote Function Status Routine is called from the Non-Surveillance Message Processing Task. Upon initiating the Backup mode, the ID of the failed site is used as an index to the tables of service areas, Master status flag settings, and Center zones. An index of zero is used for the Normal mode of operation.

A) COVERAGE WITH ALL 5 SITES OPERATING

B) COVERAGE WHEN SITE 0010 FAILS. MASTER SITE USES FAILED SITE'S ID IN CENTER ZONE

18. PERFORMANCE MONITOR

This section develops functional requirements for the Status Monitoring and Reporting (SMR) Function of ATARS. The ATARS SMR provides start and stop control indication to the local ATARS function executive processing routine. In addition the SMR monitors the status of the various functional modules, buffers and files of ATARS. The SMR constructs and transmits messages indicating the status of ATARS.

These messages are routed to the ATARS Non-surveillance Buffer. The DABS Performance Monitor reads these messages to determine the local ATARS status. The DABS Performance Monitor also transmits these messages to NAS facilities (ATC, RMM) and clears the buffer once a scan.

The Status Messages sent to DABS have limited capacity for failure reporting. If the reportable status conditions exceed this capacity then an indication of this condition is sent in the message. In accordance with this the SMR is also capable of transmitting a complete list of status conditions to a requesting NAS facility via the ATC Coordination Buffer.

The following paragraphs describe the inputs, processing function, and outputs of the ATARS SMR.

18.1 Status Monitoring and Reporting Function Inputs

DABS Status

The local DABS sensor status as determined by the DABS Performance Monitor is reported (Status Message) to the SMR via the Non-surveillance Buffer. This status will allow the SMR to control ATARS operation depending on the operational status of the local DABS sensor. This message may also report adjacent ATARS or sensor status. Logic for such reports is contained in Section 17.

ATARS Functional Failure Conditions

These inputs consist of various failure indicators from the functional modules of ATARS. These failure indicators indicate memory utilization failure, processing truncation, and software failures.

Memory Utilization Failure Indication

There are three categories of failure indicators for memory utilization. These are: output buffer overflow, file more than 90% full, and no more space in file. These are described below.

Output Buffer Overflow

This condition is reported for all ATARS buffers (see Figure 3-3) and specifies the applicable buffer.

File More than 90% Full

The SMR monitors the degree of ATARS file utilization and reports any condition of over 90 percent full for the following files:

1. Central Track Store
2. Conflict Tables
3. PWILST's
4. Encounter Lists

No More Space in File

This condition is reported for the same files listed in paragraph above.

Processing Truncation

The ATARS executive program reports any occurrence of an ATARS task being truncated due to a processing timing deadline. The report identifies the task and the sector of data for which processing was truncated.

Software Failures

This condition is unusual and is detected with the use of sector flags or other suitable indicator. The indicator shall be set by each of the ATARS functions when reporting their status for the SMR. When the SMR reads the status each scan it updates this indicator. If the SMR finds any indicator not properly updated, a failure is declared.

Request Full ATARS Status Control Message

This message from NAS to ATARS controls ATARS SMR reporting. The format is contained in Reference 8.

This message is processed by the SMR as described in Section 18.2. The following sections describe the control field in this message.

Field CTLTX

This two bit field is for transmission control of all active condition codes to a requesting NAS facility. The interpretation is as follows:

- 00 = transmit all condition codes for one scan
- 01 = transmit all condition codes repeatedly for NSMR scans
(a system parameter) unless told to stop
- 10 = stop transmission of all condition codes
- 11 = not used

18.2 Status Monitoring and Reporting Function Processing

This section describes the processing tasks to be performed by the SMR.

18.2.1 Local ATARS Processing Control

The SMR controls the commencement and cessation of local ATARS processing under the following conditions.

1. DABS/ATARS local sensor start up: (Reference 1)
 - a. Cold start
 - b. Warm start
2. Failure of the DABS portion of the local sensor
3. Failure of the ATARS portion of the local sensor

Commencement of ATARS activity will occur under item 1 above when all the ATARS functions have begun to set their software failure check indicators.

Cessation of ATARS activity will occur for items 2 and 3 above. An ATARS failure will be declared after one scan of operation with a red condition indicator if the red condition is not cleared.

18.2.2 Message Generation and Processing

The ATARS SMR processes the indicators and control message described in Section 18.1. Two outputs are constructed in each scan (see Reference 1):

1. ATARS Status Message to sensor. This message is used to notify the sensor of the operation or failure of the local ATARS function. The sensor is expected to utilize this data in its Status Message sent to adjacent ATARS functions.
2. ATARS Status Message to ATC. This output is one of the three types of messages listed below. Their formats are defined in Reference 8, with additional detail in Section 18.3 below. These messages convey to ATC a more detailed description of the local ATARS status. The messages are:

ATARS Green Condition
 ATARS Yellow Condition Codes
 ATARS Red Condition Codes

These messages may be read by a local Status Monitor Display for the sensor.

The ATARS SMR maintains a current determination of the local ATARS status. This status may be classified as "Green" (normal operation), "Yellow" (marginal operation), or "Red" (Failed). The ATARS status flag shall be reported as "normal operation" when the local status is Green or Yellow, and as "failed" when the local status is Red (see Section 18.3.3).

The categories of indicators and assigned number of scans of consecutive occurrences to produce a Yellow or Red status condition are listed below:

CATEGORY	NUMBER OF SCANS TO DECLARE STATUS	
	<u>Yellow</u>	<u>Red</u>
1. Output Buffer Overflow (each buffer)	2	-
2. File 90% Full (each file)	2	-
3. No Space on File (each file)	1	2
4. Processing Truncation (each task)	1	-
5. Software Failures (each task)	1	2

Also, if two or more files are full in one scan, Red status is declared.

The SMR shall construct a list of active Yellow and Red condition codes. These codes identify all buffers, files, tasks, and services which meet an identified failure condition, and specify the failure condition for each.

If none of the above categories of indicators have occurred, then the local status is Green. If any Red condition has occurred, the local ATARS status is Red. If no Red condition has occurred, but any Yellow condition has occurred, the local ATARS status is Yellow.

The ATARS Status Message to ATC shall be determined from Table 18-1. The following paragraphs describe these messages and specify the processing to be performed when the number of active condition codes exceeds the number of available fields in the indicated message.

ATARS Green Condition Message

The Green condition implies ATARS is fully operational.

ATARS Yellow Condition Codes Message

This Yellow condition is a warning that ATARS is functioning at a reduced service level. The Yellow Condition Codes Message, with field ALL = 0, may specify up to 25 Yellow condition codes. These condition codes describe specifically how ATARS is operating at a reduced level.

If there are more than 25 Yellow condition codes active, the Last Condition Code Message/Overflow (LM/OVF) flag is set in the message. The monitoring facilities (ATC, RMM) may request full status reporting using the message specified in Section 18.1. The SMR performs the requested action in the message.

ATARS Red Condition Codes Message

The Red condition indicates some portion of the ATARS software has failed. After the detection of this code the SMR halts local ATARS processing according to the rules in Section 18.2.1. However, the SMR continues to transmit upon request any existing Yellow condition codes as well as the Red condition codes which were active as of the time of shut down.

TABLE 18-1
SELECTION OF STATUS MESSAGE TO ATC

<u>LOCAL ATARS STATUS</u>	<u>ALL CODES REQUEST STATUS</u>	<u>MESSAGE SENT</u>
Green	Any	ATARS Green Condition
Yellow	Yes	ATARS Yellow Condition Codes (field ALL = 1)
Yellow	No	ATARS Yellow Condition Codes (field ALL = 0)
Red	Yes	ATARS Red Condition Codes (field ALL = 1)
Red	No	ATARS Red Condition Codes (field ALL = 0)

If there are more than five Red condition codes active, or any Yellow condition codes in addition to the Red condition codes, the LM/OVF flag is set in the Red Condition Codes Message. ATC must request all condition codes in this case to be sent any Yellow codes. Yellow codes would be sent in a separate message, even if the Red Condition Codes Message had unused fields.

18.2.3 Request Full ATARS Status Control Message Processing

The actions to be taken by the SMR upon the receipt of this message depend on the specified transmission control (see Field CTLTX, Section 18.1) as follows:

Transmit All Condition Codes for One Scan

The SMR transmits to the requesting facility all the currently active condition codes (Red and Yellow) using as many messages as necessary. If there are none, the ATARS Green Condition Message is sent. The SMR uses the appropriate condition codes messages (field ALL = 1) for Red or Yellow codes. Each message specifies up to 50 condition codes. As many messages shall be transmitted as are needed to transmit all active condition codes. The Last Condition Code Message/Overflow bit is set in the last Red or Yellow code message.

Transmit All Condition Codes Continuously

Yellow and Red codes active during a scan are transmitted once a scan for as many scans as they exist, for a maximum of NSMR scans, with NSMR a site adaptable ATARS parameter. After NSMR scans, the "All Codes Request Status" for the requesting facility is reset until a new request is received. If there are no Yellow or Red codes active at the time of receipt, the ATARS Green Condition Message is sent only once and the "All Codes Request Status" is immediately reset. If, prior to NSMR scans, all Yellow or Red condition codes revert to Green, the ATARS Green Condition Message is sent once and the "All Codes Request Status" is immediately reset for each requesting facility.

Stop Continuous Transmission of All Codes

When the SMR has been transmitting all condition codes continuously, this message resets the "All Codes Request Status" for the requesting facility. Otherwise the SMR ignores the message.

18.3 Status Monitoring and Reporting Function Outputs

The outputs of SMR processing consist of the control messages to allow commencement or cessation of local ATARS processing, and the messages listed in Section 18.2.2. The following paragraphs supplement Reference 8, to define the contents of the message fields.

18.3.1 Fields in Output Messages

Field ALL

When this bit, All Condition Codes Transmission, is set to 1, the message is part of a group (one or more) of messages containing all active ATARS Yellow or Red condition codes. When set to 0, only one ATARS Yellow or Red Condition Codes Message is being transmitted. The existence of any untransmitted condition codes is indicated by the Last Condition Code Message/Overflow (LM/OVF) field defined below.

Field LM/OVF

This bit, Last Condition Code Message/Overflow, has a dual purpose depending on the value of the field ALL, described above.

When ALL = 0, this bit is interpreted as the overflow indicator bit for ATARS Yellow and Red Condition Codes Messages. LM/OVF set to 1 indicates more condition codes are currently active than are being transmitted in a single message. The maximum number of Yellow and Red condition codes that can be transmitted under this setting of ALL = 0 is 25 and 5 respectively.

When ALL = 1, this bit is interpreted as the last condition code message indicator flag and is set to 1 in the last (of one or more) condition codes message. This, when combined with the field ALL, allows transmission of all active condition codes when more than one message is required.

Field #AY

This field, used in the Yellow Condition Codes Message, is a binary integer indicating the number of Yellow condition codes contained in the message. This number is a maximum of 25 when field ALL = 0, and a maximum of 50 when field ALL = 1.

Field AY(1)...AY(n)

These fields contain the Yellow condition codes as defined in Section 18.3.2. These fields are sorted from lowest to highest binary value, the lower value codes being transmitted first.

Field #AR

This field, used in the Red Condition Codes Message, is a binary integer indicating the number of Red condition codes contained in the message. This number is a maximum of 5 when field ALL = 0 and a maximum of 50 when field ALL = 1.

Fields AR(1)...AR(n)

These fields contain the Red condition codes and are defined in Section 18.3.2. These fields shall be sorted from lowest to highest binary value, the lower value codes transmitted first.

18.3.2 Formats of Condition Codes

The general format of the condition codes is as follows:

CATEGORY	CONTENT
6	16

The assigned categories and formats are described in the following paragraphs. Each condition code may be used as a Yellow or Red code in the message fields listed in Section 18.3.1. The placement in the proper message corresponds to the status determination described in Section 18.2.

The formats of the condition codes for each assigned category are as follows:

OUTPUT BUFFER OVERFLOW

000100	SP	BUFFER
6	8	16

FILE MORE THAN 90% FULL

000110	SP	FILE
6	8	16

NO MORE SPACE IN FILE

000101	SP	FILE
6	8	16

PROCESSING TRUNCATION

000010	SECTOR	FUNCTION
6	10	16

SOFTWARE FAILURES

000001	SP	FUNCTION
6	10	16

Field BUFFER

This field identifies a buffer of concern as follows:

<u>Coding</u>		<u>Buffer</u>
0000	0001	ATARS-ATARS Coordination Buffer
0000	0010	Uplink Message Buffer
0000	0011	Non-surveillance Buffer
0000	0100	ATC Coordination Buffer
0000	0101	RAR Buffer
0000	0110	Surveillance Buffer

Field FILE

This field identifies an ATARS file as follows:

<u>Coding</u>		<u>File</u>
0000	0001	Central Track Store
0000	0010	Conflict Tables
0000	0011	PWILST's
0000	0100	Encounter Lists
0000	0101	ATARS Sector Lists
0000	0110	X/EX Lists
0000	0111	Potential Pair List
0000	1000	Resolution Pair Acknowledgement List
0000	1001	Controller Alert List
0000	1010	Deletion List

Field SECTOR

This 4-bit field identifies an ATARS sector of data which was not fully processed.

Note: Each sector of data that is not fully processed shall be separately identified by an active condition code.

Field FUNCTION

This field identifies a function of ATARS in a condition code. The values and associated functions are as follows:

<u>VALUE</u>		<u>FUNCTION</u>
000	001	Master Resolution (Normal) Task
000	010	Master Resolution (Delayed) Task
000	011	Data Link Message Construction Task
000	100	Coarse Screen Task
000	101	Traffic Advisory Task
000	110	RAR Processing Task
000	111	Aircraft Update Processing Task
001	000	Track Processing Task
001	001	Seam Pair Task
001	010	Detect Task
001	011	Conflict Pair Cleanup Task
001	100	State Vector Deletion Task
001	101	Request and Process Remote Conflict Tables Task
001	110	Conflict Resolution Data Task
001	111	Resolution Notification Task
010	000	Incoming Seam Pair Request Processing and Reply Task
010	001	Surveillance Report Processing Task
010	010	Non-surveillance Message Processing Task
010	011	New Aircraft Processing Task
010	100	Terrain/Airspace/Obstacle Avoidance Task
010	101	Resolution Deletion Task

18.3.3 ATARS Normal Operation/Failure Flag

This flag in the ATARS Status Message to the sensor is used by the DABS Performance Monitor in the DABS Status Message described in Reference 8. The SMR transmits this bit according to the following rules:

Bit = 1

This setting is used when the SMR has declared local ATARS status to be Green or Yellow.

Bit = 0

This setting is used when the SMR has declared local ATARS status to be Red (Failed).

19. DATA EXTRACTION FUNCTION

The purpose of the Data Extraction Function of ATARS is threefold: to provide the capability to conduct detailed analysis of conflict scenarios, to locate and correct erroneous code (debug), and to serve as an operations log recording important events within ATARS. A well designed data extraction capability for conflict scenario analysis should be able to incorporate the needs of the remaining two functions.

19.1 Information Recorded

The information required for analysis is (1) the results of important calculations, such as TH and TV, and (2) the logic paths taken within ATARS. Table 19-1 gives the parameters to be saved on a scan-by-scan basis for off-line analysis. Table 19-2 lists the logic paths taken in the code to be recorded. The path checkpoints are an attempt to give in summary the reason for a particular ATARS action, without the detailed decision process explicitly documented. For example, if an immediate resolution advisory is requested by the Detect Task, one wants to know which of the seven ways this can happen. A possible implementation is to have a variable with eight values, indicating how the immediate RA was generated or set to zero indicating no action through these paths occurred.

Recording of all the information in Tables 19-1 and 19-2 at all times would be very cumbersome and perhaps affect the efficiency of the ATARS. So a selection control function is required to reduce the information extracted as described. Table 19-3 defines the allowable options for extracting data. Whenever data is to be saved, i.e., removed from the ATARS system, a comparison is made to see if it corresponds to that data to be recorded for the particular mode specified for the present ATARS configuration. More than one mode can be specified. Detect Task traffic advisory operations can be requested with Master Resolution Task operations, for example. When multiple modes are specified, it is of course not necessary to record the same information twice.

Judicious placement of the selection test in the ATARS code can limit the amount of testing done for extraction. It is not necessary to test for possible extraction every time a Detect Task flag is set. It is only necessary to test at the end of detection processing for a flag set condition, since the items being saved exist until this point. The actual time or location for extraction can occur in many places and is not specified. The only requirements of such extraction are that it be editable,

TABLE 19-1

INFORMATION INCLUDED IN DATA EXTRACTION

Aircraft Description Information

1. Aircraft ID - DABS ID or ATCRBS/Radar code with surveillance file number, any CREFX entries and the AC abbreviated field in the State Vector (ACAB)
2. Sector Time for Aircraft - system variable TEN
3. ACLASS - ATARS service class, as in State Vector
4. CUNC - aircraft control state, as in State Vector
5. ATSEQ - equipage type, as in State Vector
6. ACLP - aircraft climb performance, as in State Vector

Tracking Information

7. HMS - from State Vector
8. TURN - from State Vector
9. Tracked X, Y, Z - from State Vector
10. Reported range, azimuth and mode C altitude - from DABS/ATCRBS/Radar data block in State Vector
11. Velocity (XD, YD, ZD) of the aircraft - as in State Vector
12. LOFL - local data flag, as in State Vector
13. RMFL - remote data flag, as in State Vector

Detect Information

14. ENAT - from EENTRY
15. DOT - from EENTRY
16. MD2 - from EENTRY
17. RANGE2 - from EENTRY
18. TH - from EENTRY
19. TV - from EENTRY
20. RZ - as in Detect Task
21. VRZA - as in Detect Task
22. MULT - as in Detect Task
23. FAZ - from State Vector
24. AREA TYPES for both AC - from State Vector
25. TCONV - as in Detect Task
26. TCONH - as in Detect Task
27. TFPWIV - as in Detect Task
28. TFPWIH - as in Detect Task
29. TCMDV - as in Detect Task
30. TCMDH - as in Detect Task
31. TFIFRV - as in Detect Task

TABLE 19-1
(Continued)

- 32. TFIFRH - as in Detect Task
- 33. TIFRV - as in Detect Task
- 34. TIFRH - as in Detect Task
- 35. ICAFLG - from EENTRY
- 36. CAFLG - from EENTRY
- 37. FPWFLG - from EENTRY
- 38. MTTFLG - from EENTRY
- 39. FPIFLG - from EENTRY
- 40. CMDFLG - from EENTRY
- 41. FPWFLG - from EENTRY
- 42. IFRFLG - from EENTRY

Resolution Information

- 43. PSEP matrices (QSEP, before and after PSEP, HMD, VMDA, VMDB) - as in Master Resolution Task
- 44. Pair Record on entry to RAER - as in Master Resolution Task
- 45. SNGDIM - as in Master Resolution Task
- 46. Conflict Tables - as in Master Resolution Task
- 47. Feature Evaluation vs Resolution Advisory Set - as in Master Resolution Task
- 48. MANTM - as in Master Resolution Task (Structure MODVBL)

Domino Information

- 49. Coarse Screen Limits - as in domino logic
- 50. Potential Domino Conflict List - as in domino logic
- 51. Resolution Advisory Projected Position Table - as in domino logic

Multi-aircraft Logic Information

- 52. PSEP matrices - as specified in multi-aircraft logic (not the same as 43)
- 53. Resolution Advisory vs Feature Evaluation Table - as specified in multi-aircraft logic (not the same as 44)
- 54. Conflict Tables - as specified in multi-aircraft logic
- 55. Pair Records - as specified in multi-aircraft logic

Terrain Airspace Obstacle Avoidance Information

- 56. TALRT - as in Structure TAO
- 57. OALRT - as in Structure TAO
- 58. TCALRT - as in Structure TAO

TABLE 19-1
(Concluded)

Controller Alert Task Information

- 59. RALRT - as in Structure TAO
- 60. Conflict Resolution Data Message - as in Table 11-1
- 61. Resolution Notification Message - as in Table 11-2

TABLE 19-2
LOGIC PATH CHECKPOINTS

Detect Controller Alert Paths

- a. ICAFLG is set (i.e., bypass 3/5 requirement) because:
1. Immediate range and immediate altitude is satisfied for FAZ (in controller alert determination)¹
 2. HPROX and VPROX satisfied (ibid)
 3. Dangerous maneuver detected (ibid)

CAFLG is not set because:

1. Prefiltering DOT test failed (in ac converging_or_proximate_)
2. Prefiltering horizontal test failed (ibid)
3. Prefiltering vertical test failed (ibid)
4. Controller alert inhibited, CAREQ not set (in controller_alert determination)
5. Failed horizontal tests (ibid)
6. Failed vertical tests (ibid)
7. Failed miss distance test (ibid)

Detect Resolution Advisory Paths

- b. MTFLG is set (i.e., bypass 2/3 requirement) because:
1. HPROX and VPROX set (in proximity_checks)
 2. TH below threshold and VPROX (ibid)
 3. HPROX set and TV below threshold (ibid)
 4. TH and TV below thresholds (ibid)
 5. Dangerous maneuver detected (in maneuvering_threat_logic)
- c. CMDFLG is not set because:
1. Prefiltering failed (in ac converging_or_proximate)
 2. Failed horizontal tests for threat advisory (in THREAT_TAU_AND PROXIMITY_COMPARISONS)
 3. Failed vertical tests for threat advisory (ibid)
 4. Failed miss distance tests for threat advisory in (ibid)
 5. Failed horizontal tests for resolution advisory (in RESOLUTION_TAU_AND PROXIMITY_COMPARISONS)
 6. Failed vertical tests for resolution advisory (ibid)
 7. Failed vertical divergence filter (ibid)

TABLE 19-2
(Concluded)

- d. IFRFLG not set because:
 - 1. Prefiltering failed (in ac converging or proximate)
 - 2. Failed horizontal tests for threat advisory (in THREAT_TAU_AND PROXIMITY_COMPARISONS)
 - 3. Failed vertical tests for threat advisory (ibid)
 - 4. Failed miss distance tests for threat advisory (ibid)
 - 5. Failed horizontal tests for resolution advisory (in RESOLUTION_TAU_AND PROXIMITY_COMPARISONS)
 - 6. Failed vertical tests for resolution advisory (ibid)
 - 7. Failed vertical divergence filter (ibid)
- e. The resolution advisory origin was:
 - 1. Initial resolution selection caused call to RAER
 - 2. Initial resolution selection for IFR (VFR resolution previously selected) caused call to RAER
 - 3. Positive horizontal to negative transition caused call to RAER
 - 4. Negative horizontal to positive transition caused call to RAER
 - 5. Positive vertical to negative transition caused call to RAER
 - 6. Negative vertical to positive transition caused call to RAER
 - 7. Recomputation, MD2 less than PMD, caused call to RAER
 - 8. Recomputation, ALT less than PVMD, caused call to RAER
 - 9. Model validation logic caused call to RAER
 - 10. Negative vertical to VSL transition (RAER not called)
 - 11. Recalculation of incompatible resolution advisories caused call to RAER
 - 12. Conflict Resolution Data Task called RAER

¹The capitalization conforms to the convention used in the pseudocode, where process names are all lower case and routine names are all upper case.

TABLE 19-3

SELECTION MODES FOR DATA EXTRACTION

<u>MODE</u>	<u>DESCRIPTION</u>	<u>DATA RECORDED</u>	<u>INITIATION</u>
1	Tracking Information	Table 19-1, #1-13	Whenever tracking is completed
2	Detect Summary	Table 19-1, #1-6, #35-42	Whenever a Detect Task flag is set
3	Detect CA Operations	Table 19-1, #1-36 Table 19-2, #a	Whenever CAFLG is set
4	Detect TA-prox Operations	Table 19-1, #1-42 Table 19-2, #b, c, d	Whenever PWIFLG is set
5	Detect TA-threat Operations	Table 19-1, #1-42 Table 19-2, #b, c, d	Whenever FPIFLG or PPWFLG is set
6	Detect RA Operations	Table 19-1, #1-42 Table 19-2, #b, c, d	Whenever CMDFLG is set
7	Master Resolution Summary	Table 19-1, #1-6, 46	Whenever resolution advisory is generated by RAER
8	Master Resolution Operations	Table 19-1, #1-13, #43-48 Table 19-2, #e	Whenever resolution advisory is determined in Master Resolution Task
9	Domino Operations	Table 18-1, #1-13, #49-51	Whenever domino logic called
10	Multi-aircraft Operations	Table 19-1, #1-13, #52-55	Whenever multi-aircraft logic called

TABLE 19-3
(Concluded)

11	T/A/O Operations	Table 19-1, #1-13, #56-59	Whenever TALRT, OALRT, TCALRT, RALRT is set
12	Controller Alert Operations	Table 19-1, #1-13, #60-61	Whenever message sent
		Table 19-2, #e	Whenever RAER is called from Conflict Resolution Data Task

for efficiency and ease of use, and contain all information necessary for generation of the Data Analysis Summary Chart or any subset of the chart. This form is discussed in Section 19.3.

19.2 Scope of Design and Application

The data extraction system presented has minimal impact on the ATARS software. The data is "dumped in real time". All information required to decide if the data need be recorded is available at the time for recording without modification to the present system. An apparent limitation of the design presented, is the inability to record at all times why a particular flag was not set in the Detect Task. In order to do this, the implications would be:

1. Record every time a flag is not set.

Disadvantage - Massive data handling and storage problems

Advantages - Guaranteed knowledge of reason for condition desisting
- Ability to generate all parts of data analysis summary chart

2. Record whenever flag is not set after being set on previous scans.

Disadvantage - Information must be made available from scan to scan in the Detect Task
- Global memory storage required on a per pair basis

Advantages - Guaranteed knowledge of reason for condition desisting
- Ability to generate all parts of data analysis summary chart
- Introduction of global scan-to-scan storage for decisions would allow much more sophisticated data extraction designs

While it is not possible to guarantee recording of the reason for "not acting" under the present design, it is possible to arrange the edit mode options to cover most possibilities. For example the data analysis summary chart requires the path

information in Table 19-2 items c and d, i.e, why is ATARS not giving a resolution advisory? Requesting mode 4 will record path information whenever the PWIFLG is set. Under normal conditions a resolution advisory will be requested after the PWIFLG is set and end before the PWIFLG goes off. Therefore, the resolution advisory path information is available for recording and analysis with mode 4. It is for this reason that modes 4, 5, and 6 record the same information but are initiated by different events.

Table 19-4 gives the intended use of the mode option in recording information.

19.3 The Data Analysis Summary Chart

An example of the data analysis chart is depicted in Figure 19-1. Values are provided only to illustrate the use and meaning of the various data items. This format and content have proven to be most satisfactory in studying aircraft encounters. Any encounter summaries generated from the ATARS using the specified data extraction techniques will be in this format. Notice that the data is only for one aircraft pair for the duration of an encounter. The extraction task is recording information for many encounter pairs on a scan-by-scan basis. A formatting program must first sort the recorded information by aircraft ID's. The scan-by-scan sequence can be attained by maintaining the exact sequence of the dump for aircraft and labelling each new recording of the same data item as a new scan. Alternately, the time recorded with each extracted data unit, can serve as a scan organization key.

19.3.1 The Data Analysis Summary Chart Contents

The analysis chart has five sections. These sections are denoted by the right hand margin numerals in Figure 19-1. The first is an initial conditions section, which identifies the ATARS site, the ATARS program release, and the aircraft state (controller state, equipment, ATARS service state, location, altitude, heading, speed and vertical rate of each aircraft) as defined in the first scan of information. This first section is displayed in two parts, the site name, program release, date and aircraft identities appearing on every page of the form, the aircraft state only appearing once at the beginning of the chart. The second section is a scan-by-scan summary of ATARS messages and the basic conditions causing the generation of these messages. The duration of this section is variable and is defined by the amount of information recorded, i.e., it ends

TABLE 19-4
DATA EXTRACTION SELECTION SETTINGS
FOR PARTICULAR APPLICATIONS

<u>USE</u>	<u>MODE</u>	<u>COMMENTS</u>
Debug	1	Only at test sites due to large amount of data generated
	3,4,5,6,8, 9,10,11,12	Use of these modes will allow a complete history of a scenario to be recorded, as all available information is recorded
Analysis	3,4,8,11,12	These options will generate most of the Data Analysis Summary Chart
Log	2,7	Alarm rate statistics are available from this information

FIGURE 19-1
DATA ANALYSIS SUMMARY CHART EXAMPLE
(CONCLUDED)

when the extracted information ends for the aircraft(s). The third section lists the value of important parameters at the time of a significant ATARS event, such as calling RAER. The fourth section gives the closest separation occurring during the analysis recording. The final section gives the PSEP and feature array values used by RAER. This section only appears when RAER has been used to generate resolution advisories during the course of the depicted synopsis.

The chart as presented allows for a two aircraft summary. An obstacle avoidance message however involves only one aircraft, and thus generates a chart with only a few entries. Similarly, the mode options selected in extraction will determine the information available to be included in the chart. The details of the five sections of the chart are presented next.

19.3.1.1 Initial Conditions Information

1. System - The system field indicates the origin of the data, i.e., the ATARS site name.
2. ATARS Algorithm Version - This denotes the ATARS release identifier from which data is being extracted.
3. Date and Time - The date and time (Greenwich mean) when data is first recorded. The time used is the start of the sector in which the aircraft appears. TEN is the name by which the time is referenced in the ATARS pseudocode. Either aircraft's time can be used. However, the same aircraft's time must be used throughout the encounter.
4. Aircraft Identification - This field specifies the DABS ID or ATCRBS/Radar code with surveillance file number, the nine bit abbreviated aircraft ID in the State Vector, and the CREFX entry, if any, for each aircraft in this scenario. The CREFX entry is used to establish the correspondence between two data analysis summaries for the same aircraft, both of which originated from separate ATARS sites.
5. Aircraft Control Status - The control status of the aircraft is specified in the State Vector.

6. ATARS Equipage - The equipage of the aircraft is specified in the State Vector. For an aircraft which is both ATARS and BCAS equipped, EQAB is the appropriate label. For ATARS only equipped, EQA is used, for an unequipped aircraft, UNEQ is used.
7. ATARS Service Class - The value of ACLASS is specified in the State Vector.
8. Horizontal Position, Altitude, Heading, Speed, Vertical Rate of Each Aircraft - This information is for the first scan recorded. It is available with the exception of the heading in all extraction modes. The heading can be calculated using the velocity components. The units used will be nautical miles, feet, knots, degrees, as appropriate. In general, parameters referring to the horizontal dimension are in nautical miles or knots, the vertical dimension feet or feet/second. All information related to mensuration throughout the summary chart will have these same units unless explicitly mentioned.

19.3.1.2 Scan-by-Scan Data

1. Time and Scan Number - The scan number used serves as an identifier from one scan's information to the next. As such it will always start with zero and be incremented by one regardless of the elapsed time. The time recorded is the time in seconds (to the nearest tenth) from the start time as specified in item 2 of the initial conditions field.
2. Aircraft Uplink Messages - The resolution advisories calculated in Master Resolution Task as extracted in mode 8 appear in this field. The abbreviations for the advisories are in Table 19-5. Notice that the resolution advisories print positions are one scan after the call to RAER, i.e., at the time the message is displayed in the aircraft.
3. Controller Alert Messages - Each time a controller alert message is generated and extracted under mode 12 for a particular scan, the resolutions specified are to appear in this position. The contents of the DEL field in the controller alert message for each aircraft also appear in the summary sheet. The code used for the advisories is the same as that in aircraft uplink messages. The print position is also delayed by one scan as in item (2) above.

TABLE 19-5
MESSAGE ABBREVIATIONS

<u>MESSAGE</u>	<u>ABBREVIATION</u>
Proximity	P
Threat	T
No Message	Blank
Turn Left	L
Turn Right	R
Climb	C
Descend	D
Don't turn left	NL
Don't turn right	NR
Don't climb	NC
Don't descend	ND
Limit Climb to 500 ft/min	C5
Limit Climb to 1000 ft/min	C1
Limit Climb to 2000 ft/min	C2
Limit Descent to 500 ft/min	D5
Limit Descent to 1000 ft/min	D1
Limit Descent to 2000 ft/min	D2

4. Final Approach Zones and Area Types - The appropriate zone and type for each aircraft is displayed for each scan. These parameters are extracted with options 3 and 4.
5. HMS (Horizontal Maneuver Status)/TURN (Turn Sensing Status) - These are available under any mode option.
6. CAFD/CMDFD/IFRFD, ICAFLG/MTTFLG - The path flags which are as specified with modes 4, 5, or 6. These path parameters should not be confused with the same names used for flags in the Detect Task.
7. OB/RA/TC/TR - This space refers to the terrain/airspace/obstacle avoidance flags extracted in mode 11.

19.3.1.3 Significant Event Summary Data

For each of the following events a group of parameters is recorded which describes the state of the encounter.

1. PWIFLG, FPWFLG, FPIFLG, CAFLG, CMDFLG, IFRFLG - Whenever these flags are set for the first time the parameters listed below are to be included in the encounter analysis summary. The formatting program must check the contents of each scan's dump of modes 4, 5 or 6 for these flag settings. Whenever a flag transitions from not set to set the information is displayed. It is possible for the first scan to have one of the flags set, in which case this scan's information is used.
2. Resolution Advisories Determined (RA SET) - The information for determining if this routine has been called is contained within options 8 or 12. This line may be repeated as often as resolution advisories are generated during the same scan.
3. Resolutions Dropped - This event is determined by examining the CMDFLG flag extracted under options 4, 5, and 6 for each scan appearing in the analysis summary. The transition from a set to a not set condition defines resolution advisories dropped. The scan information may not be available to determine if this condition has occurred (see Section 19.2).

4. EVENT Follow-up - Whenever resolution advisories are determined or a resolution(s) dropped condition occurs, the succeeding scan information is to be displayed. The succeeding scan may or may not be available.

The parameter values appearing with each of the above events are:

- a. Scan Number - This is an arbitrary identifier as defined in (1) in the scan-by-scan data section. This is the scan in which the event has occurred.
- b. ENAT, DOT (nmi^2/s), TH, TV, RANGE, MD, RZ, VRZ - These parameters are recorded under modes 4 or 5, and their values for the scan in question are to be printed. Notice that the range and miss distance are the square roots of the values extracted. RZ and VRZ must be defined consistently from scan to scan. The Detect Task makes no distinction between AC1 and AC2 from one scan to the next and consequently the sign of the values may alternate, as AC1 alternates with AC2. This is to be corrected in the analysis chart.
- c. TH THR, TV THR - Under these headings the appropriate threshold, TCONH(V), TFPWH(V), TCMDH(V), TFIFRH(V), TIFRH(V) for the particular flag set is shown. If both the flags are set which correspond to a line, e.g., CMDFLG/IFRFLG, display the lower of the two thresholds. In the example given IFRFLG would normally have the lower corresponding threshold, TIFRH(V).
- d. Track Crossing Angle - The angle between the aircraft headings as calculated from the velocity vectors for the appropriate scan.

19.3.1.4 Separation Summary Content

The closest point of approach shall be the minimum slant range that occurs for all scans represented on the analysis chart for one aircraft pair. The slant ranges can be calculated from the (x, y, z) positions recorded for each aircraft. Appearing with the minimum slant range are the corresponding scan number, and the horizontal and vertical components of the slant range.

19.3.1.5 PSEP and Feature Array Content

For each call to RAER the PSEP matrices and the feature evaluation versus resolution advisory set data array are to be formatted and printed. In the example a "1" indicates that the feature is true

for a given advisory set. Note that MANTM, the climb rate for each aircraft and the RASET value are also provided.

19.3.2 Formatting Requirements

For any extraction mode chosen, the system parameters (Appendix A) must also be recorded, once, for any extraction cycle. These parameters must be formatted and printed in a clear and concise manner with each value accompanied by its parameter name.

Similarly, data extracted items which are not part of the encounter analysis must be formatted and printed in a clear concise manner. These data are to be labelled and ordered by aircraft pair and within aircraft pair by scan. It shall be the user's option to determine if these additional data are to be printed (if available) in addition to the data analysis summary chart.

APPENDIX C

SYNTAX OF E PSEUDOCODE

This appendix provides a concise overview of the syntax of the pseudolanguage E. The information supplied should be sufficient to allow the reader to decipher the logic specified in this document. For a complete discussion of pseudolanguage in general and E in particular, see Reference 13.

C.1 General Information

- A. E = Eclectic System Specification Language
- B. E is similar to other pseudolanguages, except that indentation counts: no BEGIN/END, IF/ENDIF, DO/OD, etc.
- C. E character set conventions:

Underscored text denotes E constructs.
Uppercase text denotes "real" program statements.
Lowercase text denotes abstract (pseudo) statements.
Angle brackets ("<", ">") denote comments.
Semicolons are used as statement delimiters.

An example:

```
-----  
  REPEAT UNTIL (all conditions satisfied);  
    Obtain message type;  
    IF (obsolete message OR A EQ SQRT(B))  
      THEN PERFORM message_elimination;  
  ENDREPEAT;  
-----
```

- D. Identifiers have no inherent length limit. Underscores are used to break up long names, as shown in the example above.
- E. Syntax definitions below follow convention of having square brackets ("[", "]") indicate optional statement elements.

C.2 Blocks

External Blocks

TASKs and ROUTINEs are the external blocks supported by E. Although they are functionally equivalent, ROUTINEs tend to be subordinate to (i.e., invoked by) TASKs.

Syntax:

```
-----  
TASK taskname  
    [IN (input parameter(s))]  
    [OUT (output parameter(s))]  
    [INOUT (modified parameter(s))];  
    ...  
    ...  
END taskname;  
-----
```

```
-----  
ROUTINE routinename  
    [IN (input parameter(s))]  
    [OUT (output parameter(s))]  
    [INOUT (modified parameter(s))];  
    ...  
    ...  
END routinename;  
-----
```

Input parameters are read but not modified; output parameters are set by the block; modified parameters are read and then modified.

Functions may also be defined. The returned value may be assigned to the single output parameter or, alternatively, assigned to the function name itself.

```

FUNCTION functionname
    [IN (input parameter(s))]
    [OUT (output parameter)];
    ...
    ...
END functionname;

```

Invocation of External Blocks

TASKs and ROUTINEs:

```

CALL blockname
    [IN (input parameter(s))]
    [OUT (output parameter(s))]
    [INOUT (modified parameter(s))];

```

Functions are invoked by name:

```

J = SQRT(K);
L = OWNER_OF(M);

```

Internal Blocks

Internal blocks (known as processes) serve as a means of decomposing a large block (external or internal) into manageable one-page segments. They are known only to the block in which they are defined. They do not accept parameters, as it is assumed that internal blocks have access to all variables known to the invoking block.

```

PROCESS processname;
    ...
    ...
END processname;

```

Invocation of Internal Blocks

PERFORM processname;

Nomenclature of Internal Blocks

A TASK or ROUTINE might be decomposed into processes as follows:

Processes frequently invoke external blocks (TASKs and ROUTINEs).

Logic Document Organization

When pseudocode is presented in formal logic documents, each chapter is typically devoted to defining a single task. Within a task definition, the blocks of pseudocode appear in a standard sequence:

- . The task's main logic;
- . First-level processes, in order of invocation;
- . Lower-level processes, in alphabetical order.

C.3 Data Types

Variables

Variables are declared at the beginning of a block in the format shown below:

<u>BIT</u> bitname;	<single logical bit>
<u>BITS</u> stringname;	<bit string>
<u>CHR</u> stringname;	<character string>
<u>FLG</u> bitname;	<synonym for BIT>
<u>FLT</u> name;	<floating point number>
<u>INT</u> name;	<integer>
<u>PTR</u> name;	<pointer>

The precision of numeric variables and the length of strings are implementation-dependent, although comments on the declaration may be used to indicate specific requirements.

Arrays are declared by means of subscripts:

<u>INT</u> ZONES(4);	<four-element array>

E uses PL/I syntax for pointer qualification. Thus,

P→X

means "the copy of X pointed to by P."

Constants

Constants in E are variables that are assigned a value when they are declared and keep that value forever. By convention, constant names are preceded by dollar signs in E to remind the reader that they are special.

```
FLT $FTPERNM    = 6076.115;  
INT $TL        =      2;      <Turn Left>
```

On occasion, the constant is shown without a corresponding value. This convention indicates that a constant is required but that its value may be anything the system implementor chooses.

Built-in Constants

Strictly speaking, the only hard constants permitted in code are zero and one. E recognizes the logical constants \$TRUE and \$FALSE. Two special statements are provided to set and clear bits:

```
SET bitname;          <bitname = $TRUE >  
CLEAR bitname;       <bitname = $FALSE >
```

The built-in constant \$NULL defines a null pointer.

Data Structures

E provides a mechanism for grouping related variables into data structures:

```

-----
STRUCTURE structurename
  GROUP groupname
    FLT variablename
    ...
    ...
ENDSTRUCTURE;
-----

```

An arbitrary number of groups may be defined. The keyword LIKE may be used to indicate that a group is identical to another group or a structure identical to another structure.

When a variable that has been declared inside a data structure is used in code, it must be qualified with the name of the structure (and the name of the group, if needed to resolve ambiguity):

```

-----
SVECT.X = PREC.ct1_thresh.ALT;
-----

```

When groups are manipulated as a unit, the GROUP keyword may be included as an aid to the reader:

```

-----
CALL COMPUTE
  INOUT (GROUP SVECT.radar_reports);
-----

```

Expressions

E assumes the existence of the usual repertoire of built-in functions (ABS, SIN, SIGN,...). Within logical expressions, logical operators are of the form LE, LT, GE, and so on.

C.4 Flow-of-Control Constructs

E uses a set of flow-of-control constructs that incorporates structured programming principles. Readers familiar with other pseudolanguages are once again reminded that indentation counts.

IF-THEN-ELSE

This is the usual conditional. The ELSE clause is optional (but recommended in complex statements). Since readers will presumably be familiar with the syntax of this construct, the example below is meant to emphasize the effects of indentation.

```
-----  
IF (cond1)  
    THEN s1;  
        S2;  
    ELSE s3;  
        IF (cond2)  
            THEN s4;  
            S5;  
        S6;  
-----
```

IF-ELSEIF-OTHERWISE

This is the multiple-choice conditional (like SELECT-CASE in other languages). The conditions are mutually exclusive. If all the logical tests fail, the optional OTHERWISE clause is executed.

```

IF (cond1)
    THEN s1;
ELSEIF (cond2)
    THEN s2;
    ...
    ...
[OTHERWISE sn;]

```

REPEAT-WHILE

This is the first of three looping constructs. Note that the logical test takes place at the top of the loop, so that the loop may never be executed.

```

REPEAT WHILE (cond1);
    s1;
    ...
ENDREPEAT;

```

REPEAT-UNTIL

This construct is the complement of REPEAT-WHILE: the logical test is performed at the end of the loop and the loop continues while the condition is not true. The loop body is always executed at least once.

REPEAT UNTIL (cond1);

S1;

...

ENDREPEAT;

LOOP-EXITIF-ENDLOOP

This construct provides a good general-purpose looping mechanism.

LOOP;

S1;

EXITIF (cond1);

S2;

ENDLOOP;

In some cases, low-level operations within the three looping constructs (such as obtaining the next element in a linked list) will be omitted for brevity.
