1. INTRODUCTION

During the months of January, February, and March, 1980, the U. S. Army Aviation Engineering Flight Activity (AEFA) conducted natural and artificial icing tests in the vicinity of St. Paul, Minnesota. The natural events involved exposure of a fully instrumented JUH-1H "Huey" Helicopter to extended periods of flight in supercooled stratiform clouds. The artificial portion of the testing required the same aircraft to fly in the cloud produced by the helicopter icing spray system (HISS) aboard a CH-47 "Chinook" Helicopter. The tanker cloud was sampled at various water flow rates, ranges, humidities, and temperatures. During the test period, the sampling helicopter was equipped with droplet sizing instrumentation provided by Meteorology Research, Inc. (MRI). A similar program was performed during the winter of 1978-1979 (Anderson and Jahnsen, 1979)*, but nozzle reconfiguration and other modifications to the HISS were necessary to produce an artificial cloud that more closely resembled a natural one. The new nozzles required a new HISS calibration effort.

This report describes the MRI instrumentation aboard the sampling aircraft, the data reduction techniques employed, and a discussion of the results.

*Anderson, R. S., and L. J. Jahnsen, 1979: Bell Helicopter UH-1H Natural Icing Test Flights. Data Volume MRI 79 DV-1679/1 prepared for Bell Helicopter, Contract No. F573 5229.

2. INSTRUMENTATION AND CALIBRATION

The MRI instrumentation package was comprised of the following devices:

- (1) PMS* axially scattering probe (ASSP-100)
- (2) PMS Cloud Particle Spectrometer (OAP-200X)
- (3) PMS Precipitation Particle Spectrometer (OAP-200Y)
- (4) MRI Buffer Memory System (BMS)
- (5) Kennedy Fast Gap 800 bpi Tape Recorder

*Particle Measurement Systems, Inc.

One-second data from the ASSP and one of the optical array probes (OAP) is input to the BMS and output to the Kennedy recorder in 32 one-second groups. The BMS has additional capabilities that allowed analog input on 11 channels to be recorded. Three channels of the analog input were dedicated to liquid water content (LWC) devices. These instruments were the Rosemount, the Leigh MK10, and the Leigh MK12. Operator error resulted in loss of Rosemount LWC data for all but the last flight. The remaining analog channels received input from a variety of aircraft state devices. These parameters included indicated air speed, collective stick position, torque, fuel flow, altitude, and outside air temperature.

The cloud droplet instrumentation were fixed to the aircraft on two specially fabricated pylons. One pylon was designed to accommodate the ASSP-100 and the other to accept one OAP spectrometer. The two OAP spectrometers were dimensionally identical and could be interchanged as desired to accomplish specific goals.

ASSP-100

This device employs a light-scattering technique as is shown schematically in Figure 2-1. A highly collimated laser beam projects across a sample tube located on the outboard end of the instrument boom. Photo detectors measure the intensity of the light scattered out of the beam by

Figure 2-1 AXIALLY SCATTERING SPECTROMETER PROBE OPTICAL SYSTEM DIAGRAM

the cloud droplets as they pass through the sample area. For droplets in the size range measured by the ASSP-100 (3 to 45 μm), the scattered light intensity varies smoothly with droplet size as shown in Figure 2-2. The electronics and recording equipment register the observed number of droplets in each of fifteen size categories. The sample is normally one second in duration.

During the course of the test program, a noise problem became apparent in the ASSP measurement system. The cause, effect, and solution to this problem will be discussed later in this report.

Optical Array Spectrometers

The other two instruments in the MRI droplet measurement package were of the optical array type. A schematic representation of these devices is given in Figure 2-3.

A collimated laser beam is projected normal to the air flow (using mirror system) and is focused on a photo diode array. A droplet entering the light beam casts a shadow over part of the diode array, causing the recording system to register a count. The size of the droplet is determined from the number of elements in the diode array which are shadowed.

The cloud particle spectrometer and precipitation particle spectrometer function in this manner. The devices, while physically similar, contain different optics and, therefore, measure particles over different size ranges.

The characteristics of the three droplet sizing probes is summarized in Table 2-1.

Table 2-1

DROPLET SIZING PROBE CHARACTERISTICS

	Droplet Size Interval (Diameter, μm)	No. of Size Classes
ASSP-100	3-45	15
OAP-200X	35-300	15
OAP-200Y	140-2100	15

Calibration Summary

The calibration of the ASSP, OAP-200X, and OAP-200Y was accomplished in three phases: (1) the initial calibration at MRI to check the measurement setting, (2) multiple field verification checks, and (3) the final calibration at MRI. Figure 2-2 is the reference voltage and size interval curve for the ASSP with three-micron intervals. The curve is used with glass bead measurements to ensure the proper output from the photo detector. The results of the calibrations are included as calibration reports on the following pages.

The calibration values were checked by using a single size of beads for each probe periodically while in the field. The probes were also checked for end element voltage to insure alignment. The calibrations were reviewed and checked on returning of the probes to MRI to ensure data accuracy. The results of these checks indicated the calibrations remained the same during the flight test program.

Calibration of the LWC devices and the other analog instruments measured by MRI are presented in Table 2-2.

Calibration of Water Flow Meter

After the field program was completed, a recalibration of the water flow meter on-board the HISS was performed. This recalibration revealed that the actual water flow was slightly less than that indicated on the gauge during testing. The water flow rates referenced in this report are indicated flows which are related to actual flows as given below:

<u>Indicated (gal min⁻¹)</u>	<u>Actual (gal min⁻¹)</u>
4.80	4.10
6.75	6.10
8.70	7.90
10.80	9.90
12.90	11.65
14.85	14.00
19.90	18.40

3. DATA REDUCTION

The objective of this report is to provide droplet data which characterized the helicopter icing spray system (HISS) plume as it existed in the 1980 field season. Based on the data obtained during 1979, the most useful information concerning the HISS plume characteristics can be learned from vertical and horizontal surveys made under a variety of conditions with additional data on LWC variability obtained by holding in the center of the cloud.

Certain characteristics of the plume and operational restrictions resulted in a data set which required careful analysis to extract information which, as near as possible, represented the cloud penetrated by the HISS.

Due to the limited number of survey missions for which data were available and due to the careful data treatment required, a "hand" reduction was undertaken. This procedure involved reviewing the one-second droplet data obtained during the surveys.

It was found at the outset that vertical profiles provided the best characterization of the physical plume, but that steady state points provided the most reproducible LWC information.

Droplet size and LWC are dependent upon vertical position in the HISS plume. This dependency, and the absence of adequate vertical position information, made analysis of survey data difficult.

It was decided to plot all the data for each flow rate for each vertical sweep into a drop size distribution and LWC profile plot. A curve of best fit through these points represents the vertical and horizontal cross section information.

The steady state data were examined and a most representative one-second point was selected for each HISS flow rate and standoff distance. The selected one-second points compare remarkably well with both 16-second and 32-second averages for each exposure and could have been used interchangeably with those average values.

To convert the droplet count data to estimates of concentration, a series of processing steps are made. These are explained below for each of the droplet probes.

ASSP-100

The small droplet probe operated on a light-scattering principle as described in Section 2. The cross sectional area of the laser beam is given as the sample area. The sample area times the true air speed yields the sample volume, usually expressed in cubic meters. The number of droplets counted in each channel is divided by the sample volume to give a droplet count per cubic meter. The mass per droplet multiplied by the droplet count will give the LWC for each channel. The sum of all 15 channels will yield the LWC measured over the total probe measurement range. An example of the process is given below:

Assume a sample area (measured and given by the manufacturer during probe calibration) of 0.332 mm^2 and a true air speed of 46.4 m s^{-1} (90 kts); the sample volume (V_s) is given as:

$$\begin{aligned} V_s &= \text{sample area} \times \text{true air speed} \times \text{sample period} & (3-1) \\ &= 0.332 \text{ mm}^2 \times 46.4 \text{ m s}^{-1} \times 1 \text{ sec} \\ &= 1.54 \times 10^{-5} \text{ m}^3 \end{aligned}$$

then given 30 counts in the 21 μm channel yields;

$$\begin{aligned}\# \text{ m}^{-3} &= 30/1.54 \times 10^{-5} \text{ m}^3 \\ &= 1.94 \times 10^6 \text{ 21 } \mu\text{m} \text{ drops in a cubic meter}\end{aligned}\quad (3-2)$$

the mass of a 21 μm diameter drop can be calculated as:

$$\begin{aligned}\text{volume} &= 4/3 \pi \left(\frac{21}{2} \mu\text{m}\right)^3 \\ &= 4.85 \times 10^{-9} \text{ cm}^3\end{aligned}\quad (3-3)$$

but for water, $1 \text{ cm}^3 \approx 1 \text{ gram}$ so the mass is given as $4.85 \times 10^{-9} \text{ g}$

the liquid water content of the 21 μm channel can be expressed as

$$\begin{aligned}\text{LWC}_{21} &= 1.94 \times 10^6 \text{ m}^{-3} \times 4.85 \times 10^{-9} \text{ g} \\ &= 0.009 \text{ g m}^{-3}\end{aligned}\quad (3-4)$$

Optical Array Spectrometers (Data Reduction)

Droplets larger than 45 microns were measured with optical array spectrometers (either the cloud particle spectrometer or precipitation particle spectrometer). These devices generate count data for 15 drop size classes which can be converted to estimates of the actual drop concentrations.

The form of the conversion equation is similar to that of the ASSP, however, for optical array probes, sample area varies with channel number as

$$A_i = \Delta D \times (K - i) \times L \quad (3-5)$$

where

ΔD = nominal channel width (drop size interval)

and

L = 6.1 cm

K = $N-1$

where

N = number of sensitive elements in the photodiode array

Sample areas used in the analysis of cloud probe data require a correction for depth of field. This correction applies to size classes one through seven and has the following form:

$$A_{1-7} = A_i \times \left(\frac{i}{8}\right)^2 \quad (3-6)$$

where

A_i is calculated as in Equation (3-5)

A summary of sampling characteristics of the droplet probes is presented in Table 3-1.

The data reduction scheme described yields droplet concentration estimates for the various drop sizes measured by the probes. This is the basic parameter describing the drop size distribution, and the parameter which can be used to calculate such things as particle concentration, mean particle size, liquid water content, median volume diameter, etc.

The measured droplet concentrations are presented in a series of figures in the next section. Logarithmic scales are used for both concentration and drop diameters since each varies over several orders of magnitude.

For each number distribution figure, a mass distribution is included. Mass distribution is simply droplet concentration weighed by the mass of a droplet of the appropriate size,

$$m_i = \frac{\pi}{6} D_i^3 \times \text{density of water}$$

then

$$M_i = \rho_i \times m_i$$

where

$$M_i = \text{quantity plotted in Section 4}$$

$$\rho_i = \text{droplet concentration as given in Section 4}$$

$$m_i = \text{mass of droplet of size observed in Channel } i$$

An inventory of all data tapes recorded is given in Table 3-2, and the chronology of the field program is given in Table 3-3.

Evaluation of Noise Problem

Early in the field program, constant counts in Channel 1 of the ASSP were detected. The counts were near 1900 per second. While the source was unknown, the number was considered insignificant since the LWC contained in Channel 1 is very small. For example, the maximum number of counts possible in the first channel is 9999 and, at 90 knots true airspeed, that amounts to a maximum of 0.009 g m^{-3} LWC. As the program progressed, a factor of two in LWC became apparent in the HISS Measurements. While the factor was cause for concern, recalibration of the ASSP revealed no apparent probe problems. Since the ASSP and the other LWC devices have historically not compared behind the HISS and since the vertical variation of LWC was large, it was concluded that possibly the LWC measurement might be reasonable. However, when the factor of two was evident in natural icing events, real alarm prevailed since the other LWC instruments and the ASSP are in close agreement under those conditions. After two recalibrations in the field indicated no apparent problem, the probe was hand-carried to the manufacturer for complete checkout. The manufacturer could detect no hardware problem with the instrument, but mentioned that the noise in Channel 1 could be enough to disable the velocity rejection circuitry. The velocity rejection feature of the probe eliminates those droplets which pass through the fringe areas of the sampling beam and are thus not sized correctly. This is done by computing an average beam transit time (electronically, a pulse width) for the particles and rejecting all particles with transit times shorter than the average. Nominally, this value is near 50 percent for the sampling techniques and airspeed in this program. When noise is introduced, it is interpreted as an immense number of particles with very short transit times. The average particle transit time becomes severely biased toward the short end and thus all real particles, whether in the fringe area or not, are larger than the average and accepted. On the premise that the noise was the problem, a search for the cause was started. No clear-cut source was found, but the

data cable to the probe and electronics box was replaced. The noise vanished in ground testing after cable replacement but soon returned in-flight and in successive flights. It was then determined that complete change of instruments was necessary. A new ASSP and electronics box was installed and the noise problem was eliminated. To recover the data obtained with the previous probe, a series of tests was performed on the aircraft while under its own power. The results of this test are given in Table 3-4. The testing showed the problem was unique to 400 Hz aircraft power and the old ASSP-electronics system. Furthermore, the 400 Hz was reproduced in the laboratory and shown to disable the velocity rejection.

The procedure to recover the old ASSP data was straightforward. The flights where that sampling system was flown were examined for noise. The analysis revealed a constant noise value of 1900 ± 10 percent for all flights except those when the cable was changed (#19, #20). For those flights where constant noise was observed, the velocity rejection was simulated numerically by reducing the counts per channel by one-half. In addition, 1900 counts were subtracted from Channel 1. The LWC obtained from this procedure compares favorably with calculated LWC for this HISS and with the other LWC devices in natural icing encounters. The noise problem had no effect on MVD calculation. Further laboratory testing is being undertaken to establish a hardware fix to the system so the probe may be returned to service.

4. DISCUSSION

This section presents the results of analysis of the data collected during the field program. There are five parts to the discussion: a physical description of the HISS cloud, the effects of changing water flow rates, the humidity effects on droplet distributions; the range or standoff effects; and the comparison of these data with the 1978-1979 program results. However, before those items are discussed, a few general comments on the artificial cloud environment and measurement techniques should be mentioned.

First, in a natural cloud, the median volumetric diameter (MVD) is a good indicator of the central point in the distribution about which most of the mass is clustered. In an artificial cloud, the MVD can be misleading without some measure of the mass dispersion. Mass can extend in droplets as large as $220\text{ }\mu\text{m}$, but be compensated by droplets in the small end of the spectrum, yielding a reasonable MVD. Fortunately, in the present HISS cloud, at nominal water flows, most of the mass is confined in a fairly narrow band between 15 and $45\text{ }\mu\text{m}$. However, some mass is present at the larger droplet ranges and must be considered when examining ice buildup and component performance.

Second, natural cloud distributions can be represented as smooth curves in both droplet concentration and mass concentration plots; this is not the case for artificially produced clouds. Even the best performing nozzles have preferred droplet sizes in multiple areas of their distributions. These "humps" in an otherwise smooth distribution curve become greatly exaggerated when the nozzles "break down" (that is, when they are operated outside the recommended performance envelope). Typically, this occurs when the water pressure (flow rate) exceeds the air pressure and the nozzles begin to sputter. Frequently, this sputter or breakdown is evident as a change in droplet size distribution well before it is visible, if ever, to the eye.

Finally, the accuracy of the LWC measurement using the laser probes must be addressed. The probes are designed as droplet sizing instruments, not LWC devices. In the ASSP, the droplets are sized in 15 channels of $3\text{ }\mu\text{m}$ bandwidth. For example, the counts in Channel 7 ($21\text{ }\mu\text{m}$), represent droplets between 19.5 and $22.5\text{ }\mu\text{m}$. This range is not a significant difference in size, but the range can be significant in LWC. The LWC contained in each channel is the product of the number of droplets counted and the mass of the droplet at the channel midpoint (in this example, $21\text{ }\mu\text{m}$). For illustration, assume a droplet count of $0.167 \times 10^8 \text{ # m}^{-3}$: for $21\text{ }\mu\text{m}$ droplets, this yields 0.08 g m^{-3} liquid water; for $22.5\text{ }\mu\text{m}$ droplets (the upper limit of the size bin), the LWC is 0.10 g m^{-3} . This is a difference of 25 percent in Channel 7 alone and arises from the fact that, while size change is linear, volume increases as the cube of the radius. Of course, while 25 percent overestimation in LWC is entirely possible, the droplets might easily have been 19.5 instead of $21\text{ }\mu\text{m}$, and an underestimation would result. The point is that a variation of 10 to 20 percent in LWC is a reasonable figure.

Physical Cloud Description

Early in the data analysis effort, it became clear that both MVD and LWC varied significantly in the vertical across the HISS plume. These effects greatly complicated efforts to determine "mean" drop size distributions for the vertical plume surveys.

To illustrate the variation of droplet size, a diagram of MVD vs vertical position in the HISS Plume is presented in Figure 4-1. This figure is constructed from the second-by-second data for a series of vertical sweeps of the HISS plume.

Figure 4-1 illustrates that droplet size increases from near 30 microns at the top of the visible plume to more than 50 microns at the bottom. This "size sorting" effect is consistent with the buoyant effects

Figure 4-1 VERTICAL VARIATION OF MVD IN THE HISS CLOUD

observed for small drops. The increase in MVD is not due to an increased number of larger droplets at the bottom but rather to the absence of smaller ones. The increase of MVD at the bottom of the cloud occurs at extremely low LWC and should be no reason for concern. As is obvious from Figure 4-1, the current HISS cloud represents a vast improvement over the 1978-1979 cloud in MVD in all areas of the plume.

The variability of LWC observed in vertical sweeps of the HISS plume is illustrated in Figure 4-2. The three vertical profiles presented in this figure show a core of high LWC slightly below center bounded above and below by regions with lower LWC. Figures 4-3 through 4-5 illustrate how well the LWC curve fits the observed data. The consistent below center bulge at all water flow rates seems to indicate that the lower HISS boom is expelling more water than the upper boom.

It is clear from Figure 4-2 that observations of plume LWC are subject to large effects for relatively small vertical displacements. Note that a 1-foot displacement upward from cloud center at 5 gal min⁻¹ could result in a decrease in measured LWC from 0.4 g m⁻³ to less than 0.3 g m⁻³. Also note that the constant cloud center measurement point apparently are not at the point of peak, in-cloud LWC. Furthermore, neither the measured center point nor the peak point in LWC would be the LWC to characterize the average cloud. In fact, the area under each curve represents the total LWC contained in the cloud. Table 4-1 illustrates the average cloud LWC and values above and below cloud center. The average cloud LWC should compare with calculated LWC given an assumed cloud size and water flow rate. Figure 4-6 shows the LWC variation in the cloud for horizontal sampling sweeps. The curves show a steep "tailing" at the cloud edges and relatively constant values in between. No MVD plot is presented since no discernible change could be noted from side to side.

³LWC 2 feet below center cloud

Flow Rate Effect

During most HISS sampling flights, a steady state point was measured near the cloud center. The procedure was to hold the probes near the center for about 30 to 120 seconds at each of the various water flow rates. A plot of water flow rate versus measured LWC is given in Figure 4-7. The two solid lines represent the LWC expected if all the water available at each flow rate was distributed uniformly throughout the entire 8 ft x 32 ft and 8 ft x 36 ft cloud areas. Most points lie slightly above and parallel to the 8 ft x 32 ft line. The measured LWC is expected to be greater throughout both areas than the expected average LWC since the LWC in center cloud is greater than the average LWC due to the variation of LWC in the vertical. The scatter of most points is $\pm 0.05 \text{ g m}^{-3}$ which is remarkable considering they were measured on different days under different conditions. The scatter becomes greatly increased when water flows become greater than 20 gal min^{-1} .

Figure 4-7 MEASURED LWC vs FLOW RATE FOR THE 1979-1980 HISS

Water pressure overcomes air pressure at flows greater than 20 gal min⁻¹ and as the control on the nozzles breaks down, measured LWC values become erratic and unreliable. Figures 4-8 and 4-9 show the effects of nozzle breakdown in number and mass distribution. Nominally, an insignificant amount ($<0.05 \text{ g m}^{-3}$) amount of mass was present in the precipitation probe (droplets $>140 \mu\text{m}$) but, at the few high water flow rate points tested, there did appear to be larger droplets. In Figure 4-7, Flight #27 LWC appears much lower than the other flights. This might be due to the fact that those points were sampled under gusty, high wind conditions and either the cloud was larger (about 8 ft x 40 ft) or a stable cloud center point might not have been achieved. Figures 4-10 through 4-13 show droplet and mass concentrations for three different flow rates. In each case, the number concentration and mass increases with increasing water flow. The MVD also increases slightly with water flow from near 20 μm at 5 gal min⁻¹ to 28 μm at 20 gal min⁻¹.

Figures 4-14 and 4-15 present droplet concentration data on two occasions with differing relative humidities. The selected points were made at the same standoff range and LWC to minimize the effect of these variables.

The high and low relative humidity (RH) examples presented in Figures 4-14 and 4-15 have similar droplet concentrations in the 25 to 45 micron size range. The low RH case, however, exhibits a much lower concentration of small droplets (<20 microns). This feature is consistent with evaporative effects but may include the effects of other variables such as air temperature.

The effect of standoff range is illustrated in Figure 4-16 and 4-17, which present drop size distributions for 150 and 300 ft. No significant range effect could be determined.

Comparison with 1978-1979 HISS and Natural Clouds

Figures 4-18 and 4-19 show the marked improvement of the current HISS over the past HISS configuration. Note the greatly increased number of droplets in sizes less than $30\text{ }\mu\text{m}$. In fact, the increase in number is about two orders of magnitude. Also greatly reduced in number are droplets larger than $45\text{ }\mu\text{m}$ in diameter. A one order of magnitude decrease in number can be observed in those sizes. Both of the above changes result in a significant shift of mass toward smaller droplet sizes. This results in the decrease in MVD from about $250\text{ }\mu\text{m}$ to approximately $30\text{ }\mu\text{m}$.

Natural

While the current HISS is much improved over previous versions when compared to a natural cloud, two important differences can be observed. Figures 4-20 and 4-21 compare the HISS to a natural cloud observed in the 1980 field program. First, there is still considerable mass at sizes greater than $45\text{ }\mu\text{m}$ which is absent in a natural cloud. Second, a natural cloud has both its mass and number concentration peaked steeply about the MVD. While the HISS cloud peaks near the MVD, the peak is much broader indicating the presence of both larger and smaller droplets. Figures 4-22 and 4-23 show the droplet concentration and mass distributions for 3 natural clouds sampled during the 1979-80 HISS program.

ASSP LWC (GM-3)	grams per m^3	LWC in ASSP
CPS LWC (GM-3)	grams per m^3	LWC in CPS
ASSP Counts (CC-1)	# per cc	Total number of normalized counts in ASSP
CPS Counts (LIT-1)	# per liter	Total number of normalized counts in CPS

The spectral data are for stable, selected one-second points. These data points were selected as representative of the average data for the HISS conditions.
