# NOTICE

When Government drawings, specifications, or other data are used for any purpose other than in connection with a definitely related Government procurement operation, the United States Government thereby incurs no responsibility nor any obligation whatsoever; and the fact that the Government may have formulated, furnished, or in any way supplied the said drawings, specifications, or other data, is not to be regarded by implication or otherwise as in any manner licensing the holder or any other person or corporation, or conveying any rights or permission to manufacture use, or sell any patented invention that may in any way be related thereto.

This report has been reviewed by the Office of Public Affairs (ASD/PA) and is releasable to the National Technical Information Service (NTIS). At NTIS, it will be available to the general public, including foreign nations.

This technical report has been reviewed and is approved for publication.

| 20. ABSTRACT (Continue on reverse side if necessary and identify by block number)<br>A selective suppression of the very high frequency content of the generalized motion simulated by the original DREB computer program has led to a considerable increase in the maximum permissible time step size and hence performance simulations over relatively large time domains (several shaft revolutions) have been economically possible with the updated version RAPIDREB. Capabilities of RAPIDREB are demonstrated for both light load, low speed DMA (Despun Mechanical Assembly) ball bearings and the heavy load, high speed (cont'd) |                                     |                                                                                 |

SECURITY CLASSIFICATION OF THIS PAGE(When Data Entered)

engine type ball bearings. From the simulations obtained over a shaft revolution it is shown that the race guided cage in the DMA bearings is generally stable while the ball guided cage produces relatively noisy and to some extent unstable cage motion. The high speed engine bearing performance is simulated over more than seven shaft revolutions. The steady whirl and continued contact of the cage with the guiding race is simulated under a combined thrust and radial load applied on the bearing. Thus conditions of excessive cage wear and eventual failure are simulated.

## 1.0 INTRODUCTION

With the availability of advanced computer codes, such as the Dynamics of Rolling Element Bearings (DREB) computer program [1-5], the interest in real time performance simulation of rolling bearings has been growing rather rapidly over the past few years. The most generalized dynamic model underlining DREB has been employed for the purpose of both design and performance diagnosis in advanced rolling bearing systems. However, in spite of the rapidly advancing computer technology, the computational effort required in using DREB has proven to be a practical limitation. This is related directly to the nature of the model in the sense that the maximum step size for the numerical integration of a system of differential equations of motion is determined by the highest frequency present in the system, which is often several orders of magnitude higher than the shaft rotational speed. Thus in order to simulate effects of the order of shaft speed, integration over a very large time domain is required and since the maximum step size is limited by the high frequencies, the computing costs, specially for very low speed applications, have proven to be prohibitive. The primary objective of the present investigation is to examine the various time scales in the general behavior of a ball bearing and accordingly modify DREB to suppress the very high frequencies and thereby develop a "rapid version" of DREB, which has been called RAPIDREB.

For a typical ball bearing the high frequency present in the system is defined by the ball/race Hertzian contact. If the ball is free to translate, vibratory motion corresponding to this natural frequency has been observed. Also, as will be discussed in the next section, a relatively high frequency is also associated with the kinematics of ball motion. In order to suppress these high frequencies the ball mass center may be constrained in a suitable manner. Once this is done the step size can be made relatively large and also predictor-corrector type algorithms can be employed to considerably reduce the computing costs. However, if a cage is present in the bearing, the discontinuities associated with the ball/cage and race/cage collisions can produce stability problems for the predictor-corrector schemes and therefore such algorithms can only be effectively used in the

case of a cageless bearing, and considerable care will be required in using such algorithms when there are repeated ball/cage or race/cage collisions. In general it will be necessary to re-start the predictor-corrector process at the time of the start and end of such collisions if the collision time is large. For short collisions an explicit formula can be used during the entire collision. The ultimate integrating scheme may therefore be of a hybrid nature employing both explicit and implicit algorithm. Thus, the incorporation of both types of formulae has been one of the objectives of the present work.

The next section of this report reviews the various time scales associated with generalized motion of the rolling elements in a ball bearing. Section 3 contains the essential modifications to the existing program DREB in order to develop the RAPIDREB version. Some dynamic simulations for both the very low speed DMA\* bearings and high speed engine bearings are then presented as typical test cases demonstrating the capabilities of RAPIDREB. Descriptions of program inputs are presented in Appendix A, and typical outputs of the program are shown in Appendices B and C.

## 2.0 GENERAL TIME SCALES

The characteristic frequencies in the general dynamic performance of ball bearings normally cover a wide spectrum. Frequencies associated with the elastic contact phenomenon are on the high end while the shaft speed is on the low end of the spectrum. Fortunately for most operating environments the high frequencies are several orders of magnitude greater than the frequencies of the order of shaft revolution speed and therefore it is relatively easy to constrain the motion to eliminate all the high frequencies in order to look at the low frequency phenomenon in depth. To understand the physical mechanism behind each frequency the basic model for each interaction and the fundamental kinematics of ball motion must be reviewed.

### 2.1 Ball/Race Interaction

The normal contact loads at the ball/race interaction are computed by the Hertzian elastic contact theory. For small changes in load the non-linear Hertzian load-deflection relation can be suitably linearized.

Now if the ball is free to translate arbitrarily a vibration frequency corresponding to this spring will be observed. This has been discussed in depth by Gupta et al [6]. To review the phenomenon briefly Figure 2-1 shows typical axial and radial components of ball mass center as it travels in its orbit. The high frequency component corresponds to the elastic contact phenomenon. For most ball bearings this frequency can be in the range of 1 to 50 kHz. A large bearing will normally have a lower elastic contact frequency due to heavier balls.

Figure 2-1 also shows a distinct low frequency whose axial and radial components are  $180^\circ$  out of phase. This frequency has been termed as a kinematic frequency [6] since it is a strong function of race curvatures and it is proportional to square root of ball/race contact load. Again the actual frequency for a given bearing depends on the geometry of bearing and the applied conditions but the general range is from about 500 Hz to 10 kHz.

It is interesting to review the load dependence of both the above frequencies. The kinematic frequency, by definition, has a square root variation as dis-

Fig. 2-1 Characteristic Ball Mass Center Vibration Pattern  
in an Angular Contact Ball Bearing

cussed above and the load dependence of the elastic contact frequency can be easily shown as 1/6 power of load:

$$\text{Hertz contact load } Q = K \delta^{3/2}$$

$$\text{Stiffness } k = \frac{\partial Q}{\partial \delta} = \frac{3}{2} K \delta^{1/2} = \frac{3}{2} K \left( \frac{Q}{K} \right)^{2/6}$$

$$\text{Natural frequency} = \sqrt{\frac{k}{m}} \sim Q^{1/6}$$

Figure 2-2 shows such a dependence for a ball bearing with 12.7 mm diameter balls and 70 mm pitch diameter. It is seen that as the contact load increases the two characteristic frequencies come close together. Thus either at high applied loads or at high speeds, the distinction between the two frequencies may not be as clearly seen in the ball acceleration plots as it is seen in Figure 2-1.

## 2.2 Ball/Cage and Race/Cage Interactions

The dynamics of ball/cage interaction can be quite complicated depending on the operating conditions and the ball pocket clearances. For a simple thrust loaded condition with gravity acting along the bearing axis, the cage weight will be supported uniformly by all the balls and therefore ball/cage contact will be established in each pocket. For such a condition the elastic contact spring modeling the normal contact will produce a vibratory motion if the cage is allowed to translate axially relative to the balls. Such a phenomenon is demonstrated in Figure 2-3. Again the frequencies will be generally high compared to the shaft rotational speed.

In most instances the ball/cage contacts may be of impulsive nature and the total time of contact may be very small. A typical example is presented in Figure 2-4. Such impulsive contacts will produce definite discontinuities in the motions of both the balls and the cage and considerable care will be required in integrating the equations of motion.

## 2.3 Low Frequency Components

This class of motion basically contains frequencies of the order of race angular velocities. The components of interest generally include ball

Fig. 2-2 Variations of computed elastic contact frequency,  $\omega_e$  and bearing kinetic frequency,  $\omega_k$  as a function of ball-race contact load

802875-1

Fig. 2-3 Typical Ball/Cage Contact Vibration

Fig. 2-4 Typical Ball/Cage Collisions in an Angular Contact Ball Bearing with Combined Axial and Radial Load

angular velocity, ball orbital velocity, ball pass frequency (rate at which a given point on the race is passed by the balls) etc. All of these frequencies may not be constant depending on the operating conditions. In fact, the variation in ball angular velocity may sometimes be quite large. This can be easily illustrated if the equations of ball angular motion are written in a coordinate frame rotating with a velocity  $\dot{\theta}$  which is also the ball orbital velocity:

$$I\dot{\omega}_1 = G_1$$

$$I\dot{\omega}_2 - I\omega_3\dot{\theta} = G_2$$

$$I\dot{\omega}_3 + I\omega_2\dot{\theta} = G_3$$

Where  $I$  is the ball moment of inertia,  $\vec{\omega}$  is the angular velocity and  $\vec{G}$  is the applied moment vector.

If, for instance, the applied moment is zero, then  $\omega_1$  will be constant and  $\omega_2$  and  $\omega_3$  will be governed by

$$\dot{\omega}_2 - \omega_3\dot{\theta} = 0$$

$$\dot{\omega}_3 + \omega_2\dot{\theta} = 0$$

or  $\ddot{\omega}_3 + \omega_3\dot{\theta}^2 = 0$  assuming  $\dot{\theta}$  to be constant and also  $\ddot{\omega}_2 + \omega_2\dot{\theta}^2 = 0$ .

Thus both  $\omega_2$  and  $\omega_3$  will have a cyclic variation with a frequency of  $\dot{\theta}$ . The nature of the applied moment  $\vec{G}$  and its dependence on ball angular velocity will of course greatly influence the ultimate motion of the balls.

As will be discussed in the next section, a knowledge of all of the above characteristic motions is necessary if any constraints on the ball motion are considered. In particular the knowledge of differences between the various components will be very useful and two classes of problems may be considered:

Class I: All frequencies are of the same general order

Class II: There is a distinct difference between the "very low" and "very high" frequency components.

Class I will be relevant for a relatively large bearing operating at very high speeds and Class II will apply to most small to moderate size bearings in a wide operating environment and large bearings operating at very low speeds, such as the DMA bearings. For the Class I system a generalized motion of each element must be determined while certain constraints can be imposed on Class II systems depending on the frequency range of interest. Also, some constraints may apply to class I system if the amplitudes of motion of certain components are very small compared to other components. A more extensive discussion of this subject is presented in the next section in terms of the modifications to the computer program DREB.

### 3.0 DREB MODIFICATIONS AND RAPIDREB DEVELOPMENTS

The available Dynamics of Rolling Element Bearings (DREB) computer program has been enhanced for several added capabilities for ball bearing performance simulation. The roller bearing capabilities of DREB have been suppressed in this enhanced version named RAPIDREB. All program modifications are centered around speeding up the computation and examining the low frequency behavior in the generalized performance simulation. Hence the modifications fall in two categories:

1. Suppression of High Frequency Content
2. Improved integrating algorithms.

Aside from the above, a minor modification to extend the program capabilities to treat ball guided cages for DMA bearings has also been made. This section of the report briefly discusses all these program enhancements.

#### 3.1 Suppression of High Frequency Content

As discussed in the preceding section there are certain high frequency characteristics present in the general performance simulation of ball bearings. A careful suppression of these frequencies is necessary to efficiently simulate the low frequency phenomenon specially because the time step size in the numerical integration algorithm is determined by the highest frequency present in the system. DREB is modified in two ways to suppress the high frequency motion, e. g., ball motion constraints and suitable damping.

##### 3.1.1 Ball Motion Constraints

The very high frequency motion results from ball vibration between the two races. Both the elastic contact frequency and the kinematic frequency represent the motion of ball mass center relative to the supporting races, as discussed in the preceding section. If the applied loads on the bearing are free of any high frequency vibrational loads, the amplitudes of the ball vibration are generally small and the resulting changes in contact loads are fairly insignificant when compared with the nominal loads. Thus it may be reasonable to constrain the ball such that the ball center follows a definite path which satisfies equilibrium of all normal contact forces acting on the ball including the centrifugal forces. The traction forces,

being quite small compared to the normal forces, may be neglected in the equilibrium equations. Also an equilibrium of forces is carried out on the inner race and its motion is constrained to satisfy such an equilibrium. Such constraints are reasonable for all static applied loads and constant races speeds. They are also applicable to time varying loads and speeds provided the frequency of such variations is very small compared to the characteristic ball/race vibration frequencies. Thus moderate race accelerations and synchronous loading due to unbalance can be satisfactorily treated within the realm of such equilibrium constraints.

It is true that the process of imposing the above constraints is similar to obtaining the conventional quasi-static solutions at each time step and hence a set of non-linear algebraic equations has to be solved. This may appear to be quite time consuming but even for relatively large steps, allowable by ball/race traction phenomenon, the changes in the equilibrium conditions are rather small and therefore the convergence of the equilibrium equations is very rapid. Thus in spite of the additional effort of solving the equilibrium equations at each step, the equilibrium constraints result in a substantial reduction in the overall computational effort, primarily due to the relatively large time step size permissible by suppressing the very high frequency motion.

### 3.1.2 Damping Considerations

There may be some damping considerations which can assist in eliminating certain high frequencies. It is true that actual damping at any contact interface in the bearing is quite small and therefore the introduction of any damping will be "fictitious" with the prime objective of eliminating the high frequency response without significantly altering the very low frequency behavior.

Any contact interface can be modeled in terms of a spring with stiffness  $k$  (N/M) and a dashpot with damping  $C$  (NS/M) as shown in Figure 3-1. The contact stiffness will be known from the Hertzian contact parameters at the particular contacts and the damping coefficient will be the required input. Perhaps specification of damping will be best in terms of a damping ratio  $C/C_c$ , where  $C_c$  is called critical damping [7] corresponding to the

812820

Fig. 3-1 Simple Spring and Damper Model for any Contact Interface

undamped natural frequency of the system.

$$\text{Damping ratio } \zeta = C/C_c$$

$$\text{Where } C_c = 2m\omega_n$$

$$\omega_n = \sqrt{\frac{k}{m}}$$

Thus  $\zeta$  can be specified for the ball/race, ball/cage and cage/race interfaces. For the purpose of "real" damping  $\zeta$  will be very small for most steels but for certain nonmetals used for fabricating the cages it may be appreciable. In any event any non-zero value of  $\zeta$  will only effect the general response in the neighborhood of the undamped natural frequency  $\omega_n$  [7] and the response at very low frequencies will be practically unchanged.

Each contact interface in the bearing is modeled in terms of the above simplified vibration model and the computer program DREB is modified accordingly.

### 3.2 Integrating Algorithms

Algorithms used to integrate a system of first order differential equations may be either of implicit or explicit type. The implicit algorithms are better known as the predictor corrector formulae and such schemes can be very efficient if no discontinuities and high frequency oscillatory motions are present. These methods make use of a set of existing solutions to extrapolate to an expected solution at the current time step and this is called the prediction step. With the predicted values the derivatives are computed and corrections to the predicted values are applied in an iterative manner. Normally two to three correction iterations are enough for most non-stiff systems. If no high frequency motion exists in the bearing and if there are no discontinuities in the solutions the predictor-corrector process can provide a relatively large time step and therefore speed up the computation in the desired time domain. However, if discontinuities are present, such as ball/cage or race/cage collisions, the extrapolation process may not be realistic and the integration process as a whole will exhibit stability problems. For such cases an explicit formula, better known as the Runge-Kutta method, which makes use of only one solution to march to the

next step will probably be the best choice.

DREB is modified to incorporate both implicit and explicit methods, with appropriate step changing criterion. The step changing process generally depends on the local truncation error at each step. An estimate of this error is quite straight forward for an implicit method but it may be quite difficult for an explicit method. On the other hand treatment of variable size steps is trivial for an explicit scheme while considerable complications arise in the extrapolation process of the predictor. A special predictor-corrector formula in terms of a divided difference notation is therefore developed to efficiently carry out the extrapolation. Some suitable explicit Runge-Kutta methods are then reviewed with particular emphasis on error estimates and step changing rationale.

### 3.2.1 Adams Type Predictor-Corrector in Divided Differences

A predictor-corrector algorithm for a differential equation with one dependent variable is developed in this section. The extension of the algorithm to a system is quite obvious. Let the governing differential equation be written as:

$$\frac{\partial y}{\partial x} = f(x, y), \quad (1)$$

with initial condition  $y_0 = y(x_0)$ .

It will be further assumed that solutions in the domain  $0 \leq x \leq x_n$  have been obtained by some explicit algorithm and the predictor-corrector formula, to be developed here, will advance the solution from  $x_n$  to  $x_{n+1}$ . The process can be written as:

$$y_{n+1} = y_n + \int_{x_n}^{x_{n+1}} f(x, y) dx \quad (2)$$

With certain polynomial approximations to  $f(x, y)$ , the required algorithm can be developed. The formulation presented below is very similar to the conventional Adams-Bashford-Moulton formulae.

#### 3.2.1.1 Predictor Formula

Let the solutions ( $y_n, y_{n-1}, \dots, y_{n-N}$ ) and the derivatives ( $f_n, f_{n-1}, \dots, f_{n-N}$ ) be available at the  $(N+1)$  points ( $x_n, x_{n-1}, \dots, x_{n-N}$ ) and for any  $x$ , let the

derivative  $f(x)^*$  be a Nth order polynomial passing through the points  $(x_n, x_{n-1}, \dots, x_{n-N})$ , i.e.:

$$f(x) = f(x_n) + \sum_{i=1}^N (x-x_n)(x-x_{n-1}) \dots (x-x_{n-i+1}) f[x_n, x_{n-1}, \dots, x_{n-i}] \\ + (x-x_n)(x-x_{n-1}) \dots (x-x_{n-N}) f[x_n, x_{n-1}, \dots, x_{n-N}, \xi] \quad (3)$$

Where  $x_{n-N} \leq \xi \leq x_{n+1}$  and the conventional divided difference notation [8] is used. The divided difference notation will be convenient for step size change and will eliminate the need for interpolation to points spaced uniformly with a constant grid spacing.

The predictor formula is obtained by substituting the polynomial approximation, equation (3), in equation (2). Thus

$$y_{n+1} = y_n + \sum_{i=0}^N f[x_n, x_{n-1}, \dots, x_{n-i}] \sum_{j=0}^i \frac{x_{n+1} - x_n}{(j+1)} \cdot A_j \\ + f[x_n, x_{n-1}, \dots, x_{n-N}, \xi] \sum_{j=0}^{N+1} \frac{x_{n+1} - x_n}{(j+1)} \cdot A_j \quad (4)$$

Where  $A_j$  are the coefficients of the polynomial

$$(x-x_n)(x-x_{n-1}) \dots (x-x_{n-i}) \equiv A_0 + A_1 x + A_2 x^2 + \dots + A_{i+1} x^{i+1}$$

Note that estimate of  $\xi$  will be required in order to estimate the truncation error term of equation (4). It will be reasonable to assume  $\xi = x_{n+1}$  and the corresponding solution as the predicted value.

From computational standpoint, it may be noted that as the order N increases, the term multiplying the polynomial coefficient  $A_j$  may experience a round off problem, which can be eliminated by scaling the independent variable as

---

\* Note the change in notation: the derivative is actually a function of y also, notation used here is  $f(x) = f(x, y)$ .

$$S \equiv \frac{x - x_p}{x_{p+1} - x_p} = \frac{x - x_p}{\Delta_p} \quad (5)$$

so that the polynomial

$$(x - x_n)(x - x_{n-1}) \dots (x - x_{n-j}) \equiv \Delta_p^{j+1} (S - x_n^*)(S - x_{n-1}^*) \dots (S - x_{n-j}^*)$$

where  $x_j^* = (x_j - x_p)/\Delta_p$

Also if  $p=n$ , the integral of equation (2) takes the convenient form:

$$\begin{aligned} \int_{x_n}^{x_{n+1}} \{(x - x_n) \dots (x - x_{n-j})\} dx &= \Delta_n^{j+2} \int_0^1 \{(S - x_n^*)(S - x_{n-1}^*) \dots (S - x_{n-j}^*)\} dS \\ &= \Delta_n^{j+2} \sum_{k=0}^{j+1} \frac{A_k^*}{k+1} \end{aligned} \quad (6)$$

Where  $A_k^*$  are coefficients of the polynomial

$$(S - x_n^*) \dots (S - x_{n-j}^*) \equiv A_0^* + A_1^* S + \dots + A_{n-j+1}^* S^{n-j+1}$$

Substituting (5) and (6) in equation (4) gives the final predictor formula

$$\begin{aligned} y_{n+1} = y_n &+ \sum_{i=0}^N f[x_n, x_{n-1}, \dots, x_{n-i}] \Delta_n^{i+1} \sum_{j=0}^i \frac{A_j^*}{j+1} \\ &+ f[x_n, x_{n-1}, \dots, x_{n-N}, x_{n+1}] \Delta_n^{N+2} \sum_{j=0}^{N+1} \frac{A_j^*}{j+1} \end{aligned} \quad (7)$$

It can easily be seen from equation (5) that the coefficients  $A_j^*$  will only have to be computed if the grid in  $x$  is non-uniform.

### 3.2.1.2 Corector Formula

For the general corrector formula, let  $f(x)$  be a polynomial of degree  $M$ , passing through the  $(M+1)$  points  $(x_{n+1}, x_n, x_{n-1}, \dots, x_{n-M+1})$ . Again using the divided difference notations

$$\begin{aligned} f(x) = f(x_{n+1}) &+ \sum_{i=0}^{M-1} (x - x_{n+1})(x - x_n) \dots (x - x_{n-i+1}) f[x_{n+1}, x_n, x_{n-1}, \dots, x_{n-i}] \\ &+ (x - x_{n+1})(x - x_n) \dots (x - x_{n-M+1}) f[x_{n+1}, x_n, \dots, x_{n-M+1}, \xi] \end{aligned} \quad (8)$$

Substitution of (8) in equation (2) gives the required corrector formula.

$$y_{n+1} = y_n + \sum_{i=-1}^{M-1} f[x_{n+1}, x_n, \dots, x_{n-i}] \sum_{j=0}^{i+1} \frac{x_{n+1}^{j+1} - x_n^{j+1}}{(j+1)} B_j \\ + f[x_{n+1}, x_n, \dots, x_{n-M+1}, \xi] \sum_{j=0}^{M+1} \frac{x_{n+1}^{j+1} - x_n^{j+1}}{(j+1)} B_j \quad (9)$$

Where  $B_j$  are coefficients of the polynomial

$$(x - x_{n+1})(x - x_n)(x - x_{n-1}) \dots (x - x_{n-i}) \equiv B_0 + B_1 x + \dots + B_{i+2} x^{i+2}$$

Again an estimate of the truncation error will require the value of  $\xi$  which may be assumed as  $x_{n-M}$ , which demands that one additional data point is available. This demand is easily met if  $M \leq N$ .

Scaling the independent variable again, as done for the predictor formula will give the final corrector algorithm:

$$y_{n+1} = y_n + \sum_{i=-1}^{M-1} f[x_{n+1}, x_n, \dots, x_{n-i}] \Delta_n^{i+2} \sum_{j=0}^{i+1} \frac{B_j^*}{j+1} \\ + f[x_{n+1}, x_n, \dots, x_{n-M+1}, x_{n-M}] \Delta_n^{M+2} \sum_{j=0}^{M+1} \frac{B_j^*}{j+1} \quad (10)$$

As for the predictor formula, the coefficients  $B_j^*$  will only have to be computed for non-uniform grid. Also it can be easily seen that the truncation error will employ the last term in the divided difference table and it will be proportional to  $\Delta_n^{M+2}$ .

### 3.2.1.3 Computation of Coefficients

In order to implement equations (7) and (10) a formula for computing the coefficients of the polynomial

$$P \equiv (x - x_n)(x - x_{n-1}) \dots (x - x_{n-p})$$

will be required.

By expanding the polynomial for  $p = 1, 2, 3, 4$  and by noting the algebraic similarities in the expansions, the polynomial can be written in the following general form:

$$\begin{aligned}
 P \equiv x^{p+1} + \sum_{k=1}^{p+1} x^{p-k+1} (-1)^k \sum_{i_1=1}^{p-k+2} x_{n-i_1+1} \sum_{i_2=i_1+1}^{p-k+3} x_{n-i_2+1} \dots \sum_{i_j=i_{j-1}+1}^{p-k+j+1} x_{n-i_j+1} \dots \\
 \dots \sum_{i_k=i_{k-1}+1}^{p+1} x_{n-i_k+1}
 \end{aligned} \quad (11)$$

The above formula can be coded once the maximum value of  $p$  is assigned.

### 3.2.1.4 Step Changing Criterion

The step size can be changed at any time in the above formulation by knowing the truncation error at the preceding step size and the allowable limit. Let us assume that the order of corrector is equal to that of the predictor ( $M=N$ ) and hence the above algorithm is a  $(N+1)$  step process. The truncation error of the predictor-corrector step will now be given by the truncation error of the corrector step only [9]. Thus error committed in arriving at  $x_{n+1}$ , from  $x_n$  is given by:

$$\frac{E_{n+1}}{\Delta_n^{N+2}} = f[x_{n+1}, x_n \dots x_{n-N}] \sum_{j=0}^{N+1} \frac{B_j^*}{j+1} \quad (12)$$

An estimate of step  $\Delta_{n+1}$  in going from  $x_{n+1}$  to  $x_{n+2}$  can be obtained from the relation:

$$\Delta_{n+1} = \frac{\Delta_n}{C} \left( \frac{\epsilon}{E_{n+1}} \right)^{\frac{1}{N+2}} \quad (13)$$

Where  $\epsilon$  is the allowable truncation limit and  $C (> 1)$  is a constant, which arbitrarily reduces the computed step size with the expectation that the tolerance criterion will be met at  $x_{n+2}$ . The value of  $C$  may be selected primarily by experience, it may vary from 1.2 to 2.0. Also it should be noted that any time the step size is changed all coefficients will have to be computed for  $N+1$  steps (assuming that no step change occurs within these steps) and hence this added work may outweigh the savings in increased step size. It is therefore recommended that the step size be changed only if the following conditions is met:

$$\frac{\Delta_{n+1}}{\Delta_n} > a \quad (14)$$

Where  $a$  is a constant, again selected by experience; it may be assumed as 1.25 as a first approximation.

Equation (13) can also be used to reduce the step size at any time, if the truncation limit is not met.

From a practical standpoint, upper and lower limits to the step size are assigned and the objective of the step changing rationale is to keep the step size to a maximum within this range. Also if the truncation limit is not met for a specified number of steps then further integration should be terminated.

#### 3.1.2.5 Change of Order

A criterion for change of order is not very clear and generally a trial and error approach is used. At a given time, solutions with the order reduced and increased by one are computed and the order giving minimum truncation is selected. Similar to the step size the maximum and minimum bounds on the order should also be assigned. The maximum order can generally be determined by examining the divided differences which will generally decrease with increase of order. However, the computed values may show an increasing trend at very high order, which will commonly be due to machine round off errors. Thus the maximum order should be limited by this phenomenon. Selection of minimum order will primarily be by experience with the problem being investigated.

#### 3.1.2.6 Computational Considerations

In developing a computer code for implementing the above formulation, certain considerations will be helpful:

1. Set a maximum limit on the order and hence the number of solutions to be stored.
2. Compute divided differences of derivatives at the first call and upgrade table at subsequent calls by adding the latest solution and deleting the earliest solution.

3. Check grid uniformity and compute coefficients (in subsequent calls) only in case of non-uniformity resulting from step size change.
4. Check maximum allowable order by examining the divided difference table and make sure that the current order is less than this maximum.
5. Store the entire divided difference table in disc file at the end of the run for subsequent restarts of the program.

### 3.2.2 Explicit Runge-Kutta Type Algorithms

As discussed earlier an explicit formula is required for two purposes. First for integrating the equations in the domain of time where there are either discontinuities or large cyclic variations at relatively high frequency. Secondly an explicit formula is required to start the implicit predictor-corrector process. Also it is required that some estimate of the local truncation error be available in order to establish some criterion for changing the step size.

The existing DREB program employs a Runge-Kutta-Merson method [9] which does estimate the truncation error. It is a fourth order process and requires an additional function evaluation for estimating the error. Hence a total of five function evaluations per step are used. There have been some questions about the accuracy of the error estimate provided by this method particularly when the equations are non-linear. Hence methods due to Scranton and England have appeared in the literature [10]. The Scranton method also uses five function evaluation but the error estimate is only realistic for a single equation and its validity to a system of equations is questionable. The England method attempts to resolve this problem by an additional function evaluation per step and it is therefore a six stage process. More recently Fehlberg [11] has provided another six stage formula which has been of considerable use in recent years. Since the selection of a method really depends on the problem under consideration, which in the case of a ball bearing can be quite complicated by the operating conditions, both the formulae due to England and Fehlberg are incorporated in the RAPIDREB version of DREB.

All of the explicit formulae can be best summarized in terms of tabular notation [12]. Thus with given solution  $y_n$  at the  $n$ th step, the solution  $y_{n+1}$  at  $(n+1)$ th step is given by

$$y_{n+1} = y_n + \sum_{i=1}^n \gamma_i k_i \quad (15)$$

where

$$k_i = h f(y_n + \sum_{j=1}^{i-1} \beta_{ij} k_j) \quad i = 1, \dots, n \quad (16)$$

and the estimate of local truncation error  $E_{n+1}$  is given by

$$E_{n+1} = \sum_{i=1}^n \gamma_i^* k_i \quad (17)$$

The values of  $\beta$ ,  $\gamma$  and  $\gamma^*$  for the three methods discussed above are given in Tables 3.1 to 3.3.

All of the above methods are fourth order. For improved accuracy a higher order method may sometimes be desirable, e.g., in a detailed simulation of one ball/cage collision. With this objective a fifth order Kutta-Nystrom method [10] and a sixth order (eight stage) Huta method [10] are also incorporated in the computer program. The coefficients of these methods are given respectively in Tables 3.4 and 3.5. For these methods since  $\gamma^*$  is not available a step doubling technique is used to compute the truncation error. In other words the computation at each step is done twice, first with the prescribed step size and then with half the prescribed step size. Thus the computation with these methods can be very expensive but the solutions obtained will be extremely accurate. Just for reference purposes the classical fourth order Runge-Kutta method, the fourth order Ralston-Runge-Kutta method, and the third and second order Runge-Kutta methods are also incorporated in the computer program. Again a step doubling technique is used in all these methods and hence considerable care must be exercised in their use. The coefficients for all these methods are fairly well known and they are summarized in Tables 3.6 to 3.9 for completeness.

TABLE 3.1

### 3.3 Modifications for Ball/Cage Guidance in DMA Bearings

An analytical model for the ball guided cages has been presented earlier [13]. The model assumes a conical end on a cylindrical pocket as shown in Figure 3-2. It is really a purely geometric interaction model in the sense that the ball center is located with respect to the center of the cone base. This is shown as vector  $\vec{r}_{bp}^p$  in the pocket frame in Figure 3-2.

In order to determine the magnitude of interaction with the conical surface, it will be convenient to transform  $\vec{r}_{bp}^p$  into cylindrical coordinates  $(r, \theta, z)$  such that

$$\begin{aligned} r &= \sqrt{(\tilde{r}_{bp_1}^p)^2 + (\tilde{r}_{bp_2}^p)^2} \\ \theta &= \arctan(-\tilde{r}_{bp_1}^p / \tilde{r}_{bp_2}^p) \\ z &= \tilde{r}_{bp_3}^p \end{aligned} \tag{17}$$

The angle  $\theta$  measured as positive rotation about the  $z$  axis from the  $y$  axis will also denote the contact angle for the cage cone contact. It should be noted that if the cone exists on the inner diameter of cage the positive  $z$  axis will be pointing radially inwards and the  $y$  axis will also be rotated by  $180^\circ$ .

From simple geometry it may be shown that a unit vector along the normal to the conical surface from the center of the ball is given by

$$\vec{e}_{bp}^p = \begin{pmatrix} \cos\phi \sin(\theta + \theta') \\ \cos\phi \sin(\theta + \theta') \\ \sin\phi \end{pmatrix} \tag{18}$$

where  $\phi$  is the cone angle and the angle  $\theta$  is measured from the line denoting maximum interaction. Thus  $\theta' = 0$ , will correspond to the unit vector along maximum interaction.

The interaction  $\delta_{bp}$  is given by

Fig. 3-2 Exaggerated Pocket Geometry For a Ball Riding Cage

812825

$$\delta_{bp}(\theta') = \left(\frac{d}{2} + \Delta_{bp}\right) \cos\phi - \vec{r}_{bp}^p \cdot \vec{e}_{bp}^p - \frac{d}{2} \quad (19)$$

It may be noted that since  $\vec{e}_{bp}^p$  is a function of  $\theta'$ , the interaction will depend on  $\theta'$  and it will be necessary to determine the range of  $\theta'$  for which  $\delta_{bp}$  is negative. This range will also determine the length of interaction. Also by straightforward geometry, the relative position of the ball center and the length of the conical surface will determine if the vector  $\vec{e}_{bp}^p$  falls on the given surface or not. The interaction analysis will only be performed when the vector  $\vec{e}_{bp}^p$  falls on the given cage surface. Once the point of contact has been established the relative slip velocity can be readily defined in terms of the ball and cage velocities.

For the computed geometric interference, the normal load is approximated by either a Hertzian point or line contact, depending on the contact arc length. This is certainly an approximation because the contact between a sphere and a cone is not really Hertzian and the true solution will require a generalized three-dimensional elastic contact analysis. The tractive forces are computed by substituting the calculated slip velocities in the prescribed traction-slip relation. For the line contact the contact arc is divided into several incremental areas and an integration is performed to compute the normal and traction forces.

#### 3.4 Recommendations for Using the RAPIDREB Version of DREB

All of the above enhancements are incorporated into the DREB program to create the new version RAPIDREB. In addition, with the objective of making the program efficient for ball bearings, the roller bearing parts and some special output options of DREB have been eliminated. Depending on the operational conditions, the computation effort in RAPIDREB may be significantly reduced if proper options are exercised. Some useful guidelines to this effect are therefore presented here:

1. If elastohydrodynamic lubrication exists it is recommended that a few time steps be run on the original DREB program and typical traction curves be printed out. Thus a ball to ball variation in traction

may be studied and a judgement can be made if the traction behavior can be approximated by a single curve and thereby eliminating all EHD computations at each step. If so, such a curve must be approximated for RAPIDREB.

2. For purely thrust loaded bearings the ball constraints can be set such that the load computation is performed only once. This will significantly effect the computational effort.
3. Bearings with a combined radial and thrust load may also employ ball/race constraints by performing an equilibrium analysis at each time step. This may result in an increase in the computational effort per step but the total effort will be greatly reduced by permitting the maximum step size to be much larger in absence of any high frequency motions.
4. Considerable care must be exercised in selecting the integration method. By extensive running of RAPIDREB it is found that the predictor-corrector scheme performs very well for cageless bearings with ball/race constraints. Hence this method is not recommended for most bearings with cage, where large discontinuities in the solutions may be present. The Fehlborg and England formulae do sometimes provide an increase in permissible step size but an increased function evaluation at every step adds to the effort per step. The benefit of these methods may only be investigated for prescribed application by a few trial runs. Any of the higher order methods provide extreme accuracy but they may be very time consuming and hence these methods should only be used in very small time domains.
5. For investigating the effects of small perturbations in the operating conditions, a steady state solution under nominal conditions must be obtained first and it should be used for determining the initial conditions for subsequent parametric runs.

6. Proper error processing control must be used to process time limit errors in order to store all the generated data files in the event an CP time limit is encountered. This is normally done by using the EXIT control statement on the CDC systems.

Appendix A contains the description of the input data to the RAPIDREB versions of both the main program RDREB and the plotting program RDREBP. The plot program is almost identical to the original version except for a few enhancements for handling large quantities of data and properly truncating the curves if they exceed the plot limits. This can be easily understood from the input description in Appendix A.

#### 4.0 PERFORMANCE SIMULATION OF DMA BEARINGS

Ball bearings used in DMA (Despun Mechanical Assembly) systems are generally very large bearings operating at very low pure thrust loads and speeds. However, they are designed for a long time of continuous operation (of the order of ten years). The lubricant is sealed into the bearing at the time of assembly and hence lubricant degradation or starvation is not an uncommon problem. Also the nature of friction at ball/cage interface has been a suspect for cage instability in such applications.

Simulation of the dynamic performance of such bearings can be obtained for extended time domains by using the equilibrium constraints on ball motion in the RAPIDREB version of the computer program. This basically eliminates the ball/race natural vibration and thereby allows a substantially large time step to integrate the differential equations of motion over more than a shaft revolution. Such simulations are the subject of this section.

#### 4.1 Bearing Geometry

Two different geometrical configurations of the DMA bearings are investigated. Figure 4-1 shows the geometrical details of a 100 mm bore angular contact bearing with the cage guided on the inner race and Figure 4-2 displays the design of a 150 mm bore ball bearing with the cage guided on the balls. The guidance surface is of a conical shape and it is attached to the cylindrical pockets on the inner diameter of the cage. Details of the cage geometry are shown in Figure 4-3.

#### 4.2 Operating Conditions

Both bearings operate at relatively low pure thrust loads and speeds, which are typical of actual application. The operating condition assumed for the simulations to be presented here are:

|                 |                  |   |          |
|-----------------|------------------|---|----------|
| 100 mm bearing: | Thrust load      | = | 178 N    |
|                 | Inner race speed | = | 60 RPM   |
| 150 mm bearing: | Thrust load      | = | 534 N    |
|                 | Inner race speed | = | 62.5 RPM |

**Fig. 4-1 Geometrical Data for the 100 mm DMA Ball Bearing with Inner Race Guided Cage**

The outer race is assumed to be stationary in both cases and the operating temperature of both bearings is assumed to be 15°C. The motion of the cage is considered under the influence of gravity with the bearing axis oriented both along and normal to the direction of gravity. This is really the only factor which will promote cage motion and its interaction with the balls. The two orientations of the bearing with respect to the direction of gravity do represent laboratory conditions.

#### 4.3 Ball/Race Traction Models

Traction behavior of typical lubricants used in DMA bearings is not fully known and a number of assumptions in modelling the behavior are generally made. For the present application a lubricant called Apiezon C + 1.5% antioxidant [14, 15] is considered with the following properties under ambient pressure and at a reference temperature of 15°C.

|                                     |                              |
|-------------------------------------|------------------------------|
| Viscosity =                         | 0.38425 Pa.S                 |
| Pressure-Viscosity Coefficient =    | $8.4234 \times 10^{-9}$ 1/Pa |
| Temperature-Viscosity Coefficient = | 6000°K                       |
| Thermal Conductivity =              | 0.10 N/S/°C                  |

Since the traction parameters are not known, the following parameters, which actually correspond to a MIL-L-7808 type oil, are arbitrarily assumed for the Type I traction model discussed by Gupta et al [16].

|                                            |   |                               |
|--------------------------------------------|---|-------------------------------|
| Viscosity Parameter, $\mu^*$               | = | 0.58889 Pa                    |
| Pressure-Viscosity Parameter, $\alpha^*$   | = | $5.22136 \times 10^{-9}$ 1/Pa |
| Temperature Viscosity Parameter, $\beta^*$ | = | $2.48550 \times 10^{-2}$ 1/°K |

Also typical of the DMA bearing environment a lubricant starvation factor (distance of lubricant meniscus from the edge of the Hertzian contact zone divided by the major contact half width) of 2 is assumed.

With the above lubricant parameters and the operating conditions outlined earlier the computed elastohydrodynamic traction coefficients for the two bearings are fairly linear with the slide-to-roll ratio, in the range of 0 to 0.10, as shown in Figure 4-4. The lubricant film thicknesses are

Fig. 4-3 Geometry of the Ball Guided Cage

also listed in the figure and from these numbers it may be concluded that the assumption of full film elastohydrodynamic lubrication even under starved conditions may be fairly reasonable. If the data of Figure 4-4 is plotted as a function of the sliding speed or slip velocity, then all of the data lies on one line with a slope of 0.0410 S/M; this is because the roll speed is different for each line in Figure 4-4. Thus a linear traction curve with a slope of 0.0410 S/M is assumed for both bearings.

Friction at ball/cage and cage/race contacts is another unknown and for the present investigation a constant friction coefficient of 0.010 is arbitrarily assumed.

#### 4.4 Performance Simulations of 100 mm DMA Bearing

The first simulation with the RAPIDREB program is obtained for the 100 mm, inner race guided DMA ball bearing operating with gravity oriented along the bearing axis. In such a orientation the cage moves axially and rests on all the balls to balance its own weight. Typical ball/cage force variation is shown in Figure 4-5. The mean force is approximately equal to the cage weight. What is interesting to notice is the settling in of the ball/cage contact angle. The observed distinct frequency in this pattern is about 44.6 Hz and it is probably related to some kinematic phenomenon in the bearing; it is really much lower than the ball/cage contact frequency which is of the order of 1 kHz. Such a cyclic variation also gets transmitted to the cage angular acceleration about the bearing axis as shown in Figure 4-6, and hence to the skid parameter  $\lambda_2$  as shown in Figure 4-7. The parameter  $\lambda_2$  is defined as:

$$\lambda_2 = \frac{\text{Cage Angular Velocity}}{\text{Race Angular Velocity}}$$

From Figure 4-7 it is also seen that the cage does not experience any significant whirl. This is indicated by the parameter  $\lambda_1$  in Figure 4-7 which is defined as:

$$\lambda_1 = \frac{\text{Cage Mass Center Whirl}}{\text{Cage Angular Velocity}}$$

## A REAL TIME SIMULATION OF BEARING PERFORMANCE

Fig. 4-7 Cage Whirl and Skid Parameters for the 100 mm DMA Bearings

The sudden change from zero whirl to some vibratory motion indicates cage radial motion beyond a certain machine round off threshold set in RAPIDREB. In reality the entire whirl pattern will look like what is seen in steady state in Figure 4-7, but the magnitude of the radial motion for all practical purposes will be negligible and no interaction with the guiding race will be seen. The bearing torque variations are seen in Figure 4-8. Again the cyclic variation corresponding to about 44.6 Hz is seen in both the outer and inner race torque. The damping of the cyclic variation is due to ball/race and ball/cage friction. Under actual laboratory conditions such cyclic torque variations may exist in steady state since the bearing is constantly subjected to subtle disturbances which may be adequate to continually excite the cyclic motion.

The ball motion indicates that the conventional race-control hypotheses do not hold when the ball/race friction is quite low as in the present case. As shown in Figure 4-9 the angular velocity vector tends to orient itself along the bearing axis and hence the x component continually increases while the z component decreases. Also a small component about the y axis is developed indicating gyroscopic slip. The resulting spin-to-roll ratios are shown in Figure 4-10. Such deviations of ball velocity from the race-control hypothesis have also been observed earlier [17].

When the bearing is oriented vertically such that the cage weight now acts in a plane perpendicular to the bearing axis, the cage tends to move radially and this causes substantial variations in ball/cage interactions as the ball travels around its orbit. Also significant interaction with the guiding race is observed and some coning motion (rotation about transverse axes of the cage) is also noted. Figure 4-11 shows the ball/cage force variation. The high frequency content is generally the ball/cage elastic contact frequency and the low frequency variation corresponds to the ball orbital velocity; the simulation time in Figure 4-11 corresponds to about one shaft revolution or approximately half of ball orbit. The cage/race forces are shown in Figure 4-12. The steady magnitude of the force is of the order of cage weight although not exactly equal to it since the ball/cage forces also enter in the cage equilibrium. Although not very clear

from Figure 4-12, there is an appreciable difference between the contact forces at the two land<sup>2</sup>, which is due to the coning motion of the cage. This is better seen in Figure 4-13 where the cage angular accelerations are plotted. Most of this motion is clearly cyclic and it has both the high and low frequency content present in it. The high frequency corresponds to the ball/cage and cage/race elastic contacts while the low frequency is similar to what is seen earlier in Figure 4-5. Both the y and z components do show the low frequency but it is more clear in Figure 4-14, where the angular velocities are plotted. The magnitude of this low frequency is about 76.4 Hz compared to the frequency of 44.6 Hz shown earlier with the bearing more symmetrically oriented.

In spite of the complicated motion the cage does seem to be fairly stable with practically no whirl in steady-state as indicated by  $\lambda_1$  in Figure 4-15. Also seen in this figure is the skid parameter  $\lambda_2$ , which is also fairly stable. The bearing torque variations are shown in Figure 4-16. These variations do contain both the high and low frequency cyclic variations, although they are not very clear in the figure. The ball angular velocities, as seen in Figure 4-17, are similar to those seen earlier. Also, the deviations from the race-control hypothesis are clear in terms of the spin-to-roll ratios plotted in Figure 4-18. In addition to this it may be interesting to note the ball orbital acceleration pattern shown in Figure 4-19. The noise in the ball orbital acceleration correlates well with the noise observed earlier in the skid parameter  $\lambda_2$  in Figure 4-15. Again the high frequency content comes from the ball/cage elastic collisions, which are now continually varying as the ball travels around its orbit.

#### 4.5 Performance Simulations of the 150 mm DMA Bearing

The general behavior of the 150 mm DMA bearing with ball guided cage is relatively more noisy than the 100 mm bearing. With the gravity oriented along the bearing axis the ball/cage pocket force variation is shown in Figure 4-20. Once again the mean force balances the cage weight and the ball/cage contact angle demonstrate some cyclic variations as is seen for the 100 mm bearing (Figure 4-5). The frequency of this component is now 37.4 Hz which is not very different from 44.6 Hz observed with the 100 mm bearing. The resulting cage motion is, however, substantially noisier.

Fig. 4-20 Ball/Cage Interaction in the 150 mm Bearing With Ball Guided Cage Operating Horizontal with Gravity Acting Along the Bearing Axis

Figure 4-21 shows cage mass center accelerations. It is clear that both radial and orbital components develop beyond the threshold of machine round off errors. Although the resulting whirl motion is substantial in terms of angular velocity, the whirl radius is still small and no appreciable interaction with the pocket cone takes place. The cage whirl is indicated by  $\lambda_1$  variation in Figure 4-22. It is easily seen that once the cage starts whirling the whirl velocity oscillates by large magnitudes; this may indicate some form of instability. Cage angular velocity, indicated by  $\lambda_2$ , is, however, fairly steady after the dampening of the initial cyclic variations. The bearing torque variations are very similar to those for the 100 mm bearing, as seen in Figure 4-23.

The general motion of the ball is almost identical to that observed in the 100 mm bearing. The ball angular velocity vector, see Figure 4-24, tends to line up with the bearing axis and the race-control hypotheses do not hold, as seen by the spin-to-roll ratios in Figure 4-25.

When the 150 mm bearing with ball-guided cage is run with gravity oriented normal to the bearing axis, significant noise in the performance simulations is produced by the repeated collisions in the cage pocket. Figure 4-26 shows typical collisions with the cylindrical part of the pockets and Figure 4-27 shows interaction at the conical guidance surface. Such repeated collisions produce considerable noise in both the ball and cage motions. The ball angular velocity variations are shown in Figure 4-28 and the orbital accelerations of the ball from the repeated impacts is shown in Figure 4-29. The angular velocity of the cage indicates substantial coning motion as seen by the y and z components in Figure 4-30. The noise generated from the ball-cage collisions is also transmitted to the cage mass center accelerations as shown in Figure 4-31. Excessive cyclic whirl of the cage is produced although no significant steady whirl is observed over the short time of this performance simulation. This is seen by the  $\lambda_1$  variation in Figure 4-32. As may be expected the skid parameter,  $\lambda_2$ , does pick up the influence of the excessive ball/cage collisions.

## 5.0 ENGINE BEARING PERFORMANCE SIMULATIONS

The enhanced capabilities of RAPIDREB also apply to the high-load and high-speed engine bearings by providing bearing performance simulation over several shaft revolutions. For a given bearing and a set of operating conditions some typical performance simulations are presented in this section.

### 5.1 Bearing Geometry

The geometry of the bearing is shown in Figure 5-1. It is a 100 mm bore ball bearing with a steel cage guided on the inner race. The design corresponds to an actual test bearing at the Air Force Propulsion Laboratories.

### 5.2 Lubricant Traction Models

Conventional lubricant with the MIL-L-7808 specification is assumed. The traction behavior of this lubricant has been studied fairly extensively and the model in the original DREB program has been demonstrated to show a reasonable fit with the experimental data. The model is also built into RAPIDREB and appropriate input option is exercised to select the MIL-L-7808 model.

For the ball/cage and cage/race interfaces a hypothetical traction model (see Appendix C) is used to compute the friction forces when a metal contact takes place.

### 5.3 Operating Conditions

To simulate typical test conditions, the following operating conditions are assumed:

|                         |            |
|-------------------------|------------|
| Axial load =            | 18,000 N   |
| Radial load =           | 4,500 N    |
| Inner race speed =      | 20,000 RPM |
| Outer race speed =      | 0          |
| Operating temperature = | 330°K      |

Gravity acts normal to the bearing axis, but in this case it really plays no appreciable role because the applied forces are quite high. Radial and axial equilibrium constraints on ball motion are assumed to eliminate the high frequency ball/race vibrations. Also the quasi-static solutions are used to determine the initial conditions.

#### 5.4 Performance Simulations

Performance simulations for the engine bearing at the above conditions are obtained over seven shaft revolutions and hence definite steady state behavior can be easily understood. Typical initial parameters are illustrated in the computer output presented in Appendix C.

As might be expected in case of combined axial and radial load, the ball load and contact angles go through a cyclic variation with a frequency corresponding to the ball orbital velocity. This is seen in Figure 5-2, where over three wavelengths of variations corresponding to over seven shaft revolutions are shown. It is also seen in this figure that the race-control hypotheses do not hold here also and definite spin velocities on both races develop in steady-state. Ball angular velocities demonstrate an interesting effect, see Figure 5-3. Since the initial quasi-static solutions do not allow gyroscopic slip and exact equilibrium of moments is not satisfied, the ball immediately tends to slip about the transverse y axis due to the gyroscopic moments. This alters the x and z components also and it takes approximately two shaft revolutions for the angular velocities to develop some steady state pattern and satisfy the gyroscopic slip as permitted by the lubricant characteristics. The ball cage interactions show that about one collision in each pock takes place per revolution of the cage and the ball drives the cage (ball/cage contact angle of  $180^\circ$ ) for part of the revolution and gets driven by the cage (contact angle of zero) for the remaining part. This is seen in Figure 5-4. The ball/cage forces seen in this figure are really the collision forces and the hydrodynamic forces, being very small compared to the collision forces, are not seen in the figure. However, the ball/cage approach relative to the radial pocket clearance clearly demonstrates the transition from hydrodynamic to metal contact.

The race/cage interaction is very dynamic and interesting to note. Figure 5-5 shows the race/cage force variations at the two lands (labelled 1 and 2) on either side of the balls. Initially both lands show identical collision forces but when appreciable coning motion of the cage develops, the forces on the two lands begin to differ; this is more clear from the traction

# DYNAMICS OF ROLLING ELEMENT BEARINGS A REAL TIME SIMULATION OF BEARING PERFORMANCE

Fig. 5-5 Repeated Cage/Race Collisions in the 100 mm Engine Bearing

force curves. The ultimate behavior to note is that the race/cage collisions are really very close together in time in steady state. Also the magnitude of the force is fairly large ( $\sim 1800$  N). This means that the cage will steadily be in contact with the race with a relatively large force, and some cage wear problems may be expected. This is seen by the steady circular orbit of the cage mass center in Figure 5-6 with the orbit radius equal to the cage/race radial clearance. This effect has indeed been confirmed experimentally [18] and the experimental results will soon be documented elsewhere [19].

Corresponding to the above race/cage collisions considerable radial chatter of the cage mass center is observed, as shown in Figure 5-7 in terms of the cage mass center velocities. Excessive whirl is indicated by the increased orbital velocity. The coning motion is demonstrated by the angular velocity variations in Figure 5-8. The deviation of cage angular velocity from the initial epicyclic angular velocity (see component x) indicates substantial skid in the bearings due to excessive rubbing of the cage at the cage/race interracial. Both cage whirl and skid are better understood in terms of the parameters  $\lambda_1$  and  $\lambda_2$  respectively, as shown in Figure 5-9.

Finally, the variations of bearing torque, power loss, and the cumulative load slip integral are shown in Figure 5-10. The initial bump in the torque curves correspond to the gyroscopic slip of the balls as discussed above and the steady noise is a result of the ball/cage and race/cage collisions.

## 6.0 CONCLUSIONS AND RECOMMENDATIONS

The existing Dynamics of Rolling Element Bearings (DREB) computer program has been enhanced to selectively suppress the very high frequency vibratory motion of the balls in an angular contact ball bearing and thereby provide the added capability of investigating the low frequency phenomena in some depth. With such an enhancement a considerable increase in the maximum permissible time step size has led to bearing performance simulation over several shaft revolutions within reasonable computing effort. The updated program version is referred to as RAPIDREB. Some of the essential RAPIDREB capabilities include:

1. Radial and axial equilibrium constraints on the balls to eliminate the high frequency ball/race vibration.
2. Introduction of fictitious damping at each contact interface to selectively damp the high frequencies.
3. Incorporation of a number of Runge-Kutta type explicit formulae.
4. A predictor-corrector algorithm for conditions under which no substantial cyclic components and discontinuities in the solutions exist.
5. Option to change the integrating algorithm at any point in time.
6. Treatment of ball guided cages for very low speed ball bearings.
7. Built in options for synchronous radial loading due to unbalance or any rotating loads.

Any of the above options can be selected or the program can be run in a completely generalized mode identical to the original DREB program. It is shown that depending on the operating conditions substantial computing effort can be saved by properly selecting the constraints and the integrating method. By exercising RAPIDREB over a number of trial runs it is concluded that the predictor-corrector type of formula is only suitable when there are no discontinuities and high frequency vibratory motions in the system. Thus after suppressing the very high frequencies, the

predictor-corrector schemes offer the benefit of very large step sizes, only for the cases where no discontinuities associated with ball/cage or race/cage collisions are present. This is because extrapolation past a discontinuity results in larger errors in the prediction process. Thus these schemes are useful only for bearings either without cage or with basically hydrodynamic interaction at the ball/cage and race/cage interfaces. Considerable care in selecting the integrating method is therefore necessary.

RAPIDREB is used to produce performance simulations of two very low speed, lightly loaded DMA (Despun Mechanical Assembly) ball bearings and a typical high-load, high-speed ball bearing for engine applications. The DMA bearings have pure thrust load and therefore gravity is the only dominant factor as far as the cage is concerned. Hence both bearings are oriented such that gravity is either parallel or perpendicular to the bearing axis. The first of the DMA bearings is a 100 mm bore ball bearing with inner race guided cage. The steady state performance simulation obtained by integrating the equations of motion over more than a shaft revolution indicate that when gravity acts along the bearing axis the cage contacts all the balls and balances its own weight against the balls. No substantial cage whirl is observed in the simulation and the bearing operation is generally stable. When weight of the cage acts normal to the bearing axis variable ball/cage and cage/race interactions are observed as the balls travel in their orbit. This is basically due to the eccentric location of the cage. An appreciable coning motion of the cage is also observed in this case but again no appreciable cage whirl or skid is observed and the operation is generally stable. The second of the DMA bearings is a 150 mm bore ball bearing with a ball guided cage with a conical guidance surface attached to the nominally cylindrical pocket. Again the first symmetric case when the gravity acts along the bearing axis is similar to the 100 mm bearing and the weight of the cage is balanced against the ball/cage forces. However, large variations in cage whirl velocity are observed indicating some element of instability. The bearing performance worsens as the cage is allowed to move eccentricly under its own weight acting normal to the bearing axis. In this case large interactions at both the cylindrical and

conical parts of the cage pocket are observed. This results in a large amount of noise and greatly erratic motion of the cage.

The engine bearing performance simulations are obtained with a combined thrust and radial load (thrust to radial load ratio of 4) over more than seven shaft revolutions. The test example consists of a 100 mm bore ball bearings operating at 20,000 rpm with a thrust load of 18000 N and a radial load of 4500 N. The bearing uses a steel cage guided on the inner race. It is shown that for such an operating environment the cage develops appreciable whirl velocity and in steady state a continued metal contact at the guiding land is established. Hence a definite possibility of cage wear at the guiding surface is predicted.

Since RAPIDREB easily provides bearing performance simulations over several shaft revolutions and the prediction of steady state performance is possible with great confidence, several recommendations for future development may be listed:

1. The steady state performance predictions should be validated experimentally, particularly in terms of the cage motion. This will greatly strengthen the predictive capability of RAPIDREB and thereby enhance its value as a design tool.
2. Since solutions over relatively large time domains are now possible a graphic simulation of the various component motions in the bearing will contribute to greater understanding of the various instabilities and the dynamic behavior of the bearing as a whole. This will essentially require the development of a sophisticated graphics program replacing the current plot program.
3. RAPIDREB can be very useful in establishing direct correlations of bearing life and dynamic stability with both geometrical and operational variables. Hence it can be a very useful tool in guiding accelerated life cycle tests for long life bearings

FOR THE PERFORMANCE SIMULATION OF BALL BEARINGS, THIS PROGRAM  
IS AN ADVANCED VERSION OF THE BALL BEARING TREATMENT IN THE MTI  
DYNAMICS OF ROLLING ELEMENT BEARING (DREB) COMPUTER PROGRAM. THE  
ADDED CAPABILITIES INCLUDE --

1. SELECTIVE CONSTRAINTS OF THE AXIAL AND RADIAL MOTION OF  
THE BALLS AND THEREBY ELIMINATING HIGH FREQUENCY BALL/RACE  
VIBRATIONS.
2. DAMPING COEFFICIENTS AT ALL INTERACTIONS WHICH ALLOW FOR  
EITHER A REALISTIC INTERNAL MATERIAL DAMPING OR A  
FICTITIOUS DAMPING TO SELECTIVELY DAMP OUT CERTAIN COMPO-  
NENTS OF THE VIBRATORY MOTION.
3. A NUMBER OF DIFFERENT INTEGRATING ALGORITHMS TO INTEGRATE  
THE DIFFERENTIAL EQUATIONS OF MOTION.
4. A TREATMENT FOR A BALL GUIDED CAGE.
5. IMPROVED BALL/RACE TRACTION INTEGRAL SPECIALLY FOR  
SOLID LUBRICATED CONDITIONS.
6. SWITCH FOR SIMULATING A ROTATING RADIAL LOAD ON THE  
BEARING.

| C | CARD 19                                                            |   | RDRER629 |
| C | -----                                                              |   | RDRER630 |
| C |                                                                    |   | RDRER631 |
| C | *****                                                              |   | RDRER632 |
| C | * THIS CARD IS REQUIRED ONLY IF MODE=0 ON CARD 1.                  | * | RDRER633 |
| C | *****                                                              |   | RDRER634 |
| C |                                                                    |   | RDRER635 |
| C | 6 11-46 VECTOR OF LENGTH 3 CONTAINING THE COMPONENTS OF            |   | RDRER636 |
| C | THE ACCELERATION ( $L/T^2$ ) DUE TO GRAVITY VECTOR                 |   | RDRER637 |
| C | IN THE INERTIAL FRAME. EACH COMPONENT HAS A                        |   | RDRER638 |
| C | FIELD WIDTH OF 12.                                                 |   | RDRER639 |
| C |                                                                    |   | RDRER640 |
| C | *****                                                              |   | RDRER641 |
| C |                                                                    |   | RDRER642 |
| C | * THE FOLLOWING SERIES 20 CARDS ARE REQUIRED ONLY IF MODE=2 ON     | * | RDRER643 |
| C | * CARD 1.                                                          | * | RDRER644 |
| C | *****                                                              |   | RDRER645 |
| C |                                                                    |   | RDRER646 |
| C | CARD 20.1                                                          |   | RDRER647 |
| C | -----                                                              |   | RDRER648 |
| C | TI 11-25 INITIAL DIMENSIONLESS TIME.                               |   | RDRER649 |
| C |                                                                    |   | RDRER650 |
| C | CARDS 20.2 TO CARD 20.N                                            |   | RDRER651 |
| C | -----                                                              |   | RDRER652 |
| C | X 11-70 THE DIMENSIONLESS SOLUTION VECTOR OF LENGTH                |   | RDRER653 |
| C | ( $3U+12*NB+6*KBT/ABS(KRT)$ ) WHICH WILL BE USED AS                |   | RDRER654 |
| C | INITIAL CONDITIONS. EACH CARD WILL HAVE FOUR                       |   | RDRER655 |
| C | COMPONENTS, EACH ONE HAVING A FIELD WIDTH OF 15.                   |   | RDRER656 |
| C |                                                                    |   | RDRER657 |
| C | CARDS 21 TO .....                                                  |   | RDRER658 |
| C | -----                                                              |   | RDRER659 |
| C |                                                                    |   | RDRER660 |
| C | ANY INPUT DATA REQUIRED BY THE USER ACCESSIBLE ROUTINES -ALOAD-,   |   | RDRER661 |
| C | -PSPRG- AND -RSPRG- SHOULD BE SUPPLIED IN ORDER. (SEE DISCUSSION   |   | RDRER662 |
| C | OF SPECIAL ROUTINES BELOW).                                        |   | RDRER663 |
| C |                                                                    |   | RDRER664 |
| C | OUTPUT DATA                                                        |   | RDRER665 |
| C | *****                                                              |   | RDRER666 |
| C |                                                                    |   | RDRER667 |
| C |                                                                    |   | RDRER668 |
| C | OUTPUT SOLUTIONS MAY BE EITHER PRINTED, PLOTTED OR BOTH. AS DIS-   |   | RDRER669 |
| C | CUSSSED UNDER THE INPUT DESCRIPTIONS SEVERAL DIFFERENT OPTIONS FOR |   | RDRER670 |
| C | MONITORING THE OUTPUT ARE AVAILABLE. ALL THE OUTPUT IS VERY WELL   |   | RDRER671 |
| C | DOCUMENTED IN ORDER TO MAKE IT SELF-EXPLANATORY. ALL DIMENSIONAL   |   | RDRER672 |
| C | VARIABLES ARE PRINTED WITH PROPER UNITS.                           |   | RDRER673 |
| C |                                                                    |   | RDRER674 |
| C |                                                                    |   | RDRER675 |
| C | FILE SYSTEM                                                        |   | RDRER676 |
| C | *****                                                              |   | RDRER677 |
| C |                                                                    |   | RDRER678 |
| C | THE PROGRAM HAS FULL RESTART CAPABILITIES AND IT CAN MONITOR THE   |   | RDRER679 |
| C | MOTION OF A TOTAL OF SIX REARING ELEMENTS INCLUDING THE CAGE AND   |   | RDRER680 |
| C | THE RACEWAYS. THE ELEMENT SELECTION IS DESCRIBED UNDER THE INPUT   |   | RDRER681 |
| C | DESCRIPTION AND SOME DETAILS OF THE FILING SYSTEM ARE DISCUSSED    |   | RDRER682 |
| C | BELOW.                                                             |   | RDRER683 |
| C |                                                                    |   | RDRER684 |
| C | FILE ESOL                                                          |   | RDRER685 |

|   |                                                                    |         |
|---|--------------------------------------------------------------------|---------|
| C | -----                                                              | RDRB686 |
| C | THIS IS THE MASTER DATA FILE WHICH CONTAINS ALL THE BEARING        | RDRB687 |
| C | INFORMATION AND SOLUTION VECTORS AT SELECTED TIME STEPS. THIS      | RDRB688 |
| C | FILE MUST BE SAVED IF THE EXECUTION HAS TO BE RESTARTED LATER.     | RDRB689 |
| C |                                                                    | RDRB690 |
| C | FILE FSOL                                                          | RDRB691 |
| C | -----                                                              | RDRB692 |
| C | AT THE END OF A SUCCESSFUL RUN THE LAST SOLUTION VECTOR IS         | RDRB693 |
| C | WRITTEN IN THIS FILE IN A FORMAT SUCH THAT THE DATA COULD BE       | RDRB694 |
| C | PUNCHED ON CARDS AND DIRECTLY USED UNDER THE ARBITRARY INITIAL     | RDRB695 |
| C | CONDITIONS OPTION. THIS FILE IS COMPLETELY REWRITTEN AT THE        | RDRB696 |
| C | END OF EACH EXECUTION OF THE PROGRAM.                              | RDRB697 |
| C |                                                                    | RDRB698 |
| C | FILES GSOL1 TO GSOL6                                               | RDRB699 |
| C | -----                                                              | RDRB700 |
| C | THESE SIX FILES STORE ALL SOLUTIONS FOR THE SIX PRESELECTED BEAR-  | RDRB701 |
| C | ING ELEMENTS. IF THE NUMBER OF ELEMENTS SELECTED IS LESS THAN SIX  | RDRB702 |
| C | THEN THE FIRST FILE NUMBERS ARE FILLED. IN OTHER WORDS IF THERE    | RDRB703 |
| C | ARE ONLY THREE ELEMENTS MONITORED THEN THE SOLUTIONS ARE CONTAIN-  | RDRB704 |
| C | ED IN FILES GSOL1 TO GSOL3 AND THE FILES GSOL4 TO GSOL6 REMAIN     | RDRB705 |
| C | EMPTY. WHEN A COMPLETE CASE CONSISTS OF SEVERAL EXECUTIONS OF      | RDRB706 |
| C | THE PROGRAM, THEN IT WILL BE NECESSARY TO ATTACH ALL THE FILES     | RDRB707 |
| C | USED WITH THE PROPER WRITE PERMISSION SO THAT SOLUTIONS FOR THE    | RDRB708 |
| C | ENTIRE TIME RANGE MAY BE STORED FOR PLOTTING PURPOSES.             | RDRB709 |
| C |                                                                    | RDRB710 |
| C | FILE HSOL                                                          | RDRB711 |
| C | -----                                                              | RDRB712 |
| C | THE OVER ALL BEARING PARAMETERS, WHICH CONSISTS OF LOAD*SLIP,      | RDRB713 |
| C | TRACTION*SLIP, AND TORQUE VARIATIONS, ARE STORED IN THIS FILE AS   | RDRB714 |
| C | A FUNCTION OF TIME.                                                | RDRB715 |
| C |                                                                    | RDRB716 |
| C | ALL DATA FILES CONTAIN APPROPRIATE IDENTIFICATION CODES, WHICH ARE | RDRB717 |
| C | CHECKED WHENEVER THE FILES ARE ATTACHED. THE FILES PRODUCED WITH   | RDRB718 |
| C | TWO DIFFERENT RUNS, THEREFORE, MAY NOT BE INTERCHANGED.            | RDRB719 |
| C |                                                                    | RDRB720 |
| C |                                                                    | RDRB721 |
| C | SPECIAL ROUTINES                                                   | RDRB722 |
| C | =====                                                              | RDRB723 |
| C |                                                                    | RDRB724 |
| C | THE FOLLOWING SPECIAL ROUTINES ARE AVAILABLE TO THE USER IN ORDER  | RDRB725 |
| C | TO CLOSELY SIMULATE THE APPLICATION UNDER QUESTION --              | RDRB726 |
| C |                                                                    | RDRB727 |
| C | 1. APLOAD - APPLIED LOAD                                           | RDRB728 |
| C | 2. PSPRG - ARBITRARY SPRING AT RALL/CAGE CONTACT                   | RDRB729 |
| C | 3. RSPRG - ARBITRARY SPRING AT RACE/CAGE CONTACT                   | RDRB730 |
| C |                                                                    | RDRB731 |
| C | SEE DOCUMENTATION SUPPLIED WITH THE ABOVE ROUTINES FOR NOTES ON    | RDRB732 |
| C | PROGRAMMING THE FEATURES OF A GIVEN APPLICATION IN THE ABOVE       | RDRB733 |
| C | SUBROUTINES.                                                       | RDRB734 |
| C |                                                                    | RDRB735 |
| C |                                                                    | RDRB736 |
| C | EXTERNALS CALLED                                                   | RDRB737 |
| C | =====                                                              | RDRB738 |
| C |                                                                    | RDRB739 |
| C | THE FOLLOWING LIST OF SUBROUTINES INCLUDES THE ROUTINES CALLED     | RDRB740 |
| C | DIRECTLY BY -RDRP- AND ALSO THOSE CALLED BY THE ROUTINES           | RDRB741 |
| C | INITIALLY CALLED BY -RDRP- ---                                     | RDRB742 |

|   |     |                                                              |          |
|---|-----|--------------------------------------------------------------|----------|
| C | (2) | THE PROGRAM WITH ALL THE ROUTINES USES A CENTRAL MEMORY OF   | RDREB802 |
| C |     | ABOUT 158000B WORDS.                                         | RDREB803 |
| C |     |                                                              | RDREB804 |
| C | (3) | THIS PROGRAM HAS BEEN DEVELOPED ON THE CDC SYSTEM WHICH      | RDREB805 |
| C |     | EMPLOYS 60 BIT WORDS. ON OTHER SYSTEMS WHERE SHORTER WORDS   | RDREB806 |
| C |     | ARE USED IT MAY BE NECESSARY TO USE DOUBLE PRECISION.        | RDREB807 |
| C |     |                                                              | RDREB808 |
| C | (4) | FOR THE PURPOSE OF ROOT FINDING AND TEST AGAINST ZEROS THE   | RDREB809 |
| C |     | PROGRAM USES TOLERANCES WHICH RESIDE IN THE ARRAY TOLR IN    | RDREB810 |
| C |     | THE COMMON BLUCK TCOMA. THE ARRAY HAS THREE COMPONENTS.      | RDREB811 |
| C |     | THE FIRST AND SECOND COMPONENTS ARE TOLERANCES FOR ABSOLUTE  | RDREB812 |
| C |     | AND RELATIVE ZEROS RESPLY. THE THIRD COMPONENT IS A          | RDREB813 |
| C |     | TOLERANCE ON ACCELERATION COMPONENTS. IF ANY EXT FORCE       | RDREB814 |
| C |     | HAS AN ABSOLUTE VALUE LESS THAN THIS TOLERANCE THEN IT IS    | RDREB815 |
| C |     | SET EQUAL TO ZERO. PROPER VALUES TO THE ARRAY TOLR ARE       | RDREB816 |
| C |     | ASSIGNED IN THE BEGINNING OF THE MAIN PROGRAM -DREB-.        | RDREB817 |
| C |     |                                                              | RDREB818 |
| C | (5) | TIME STEP SIZE OPTIMIZATION IS PROVIDED BY NOPT VECTOR AND   | RDREB819 |
| C |     | THE VALUE OF TOL IN -RDREB-. TOL SHOULD BE 1 TO 2 ORDEKS     | RDREB820 |
| C |     | OF MAGNITUDE GREATER THAN THE TOLERANCE ON RELATIVE ZEROS    | RDREB821 |
| C |     | DISCUSSED ABOVE. IF THE TRUNCATION AT ANY STEP EXCEEDS TOL   | RDREB822 |
| C |     | THEN THE STEP SIZE IS SUCCESSIVELY HALVED UNTIL EITHER THE   | RDREB823 |
| C |     | TOLERANCE CRITERION IS MET OR THE MIN STEP SIZE, SPECIFIED   | RDREB824 |
| C |     | ON CARD 2, IS REACHED. IF THE TOLERANCE CRITERION IS NOT     | RDREB825 |
| C |     | MET FOR NOPT(1) CONSECUTIVE STEPS THEN THE EXECUTION IS TER- | RDREB826 |
| C |     | MINATED. A TYPICAL VALUE FOR NOPT(1) MAY BE ABOUT 3 TO 6.    | RDREB827 |
| C |     | IF THE TOLERANCE CRITERION IS MET FOR NOPT(2) SUCCESSIVE     | RDREB828 |
| C |     | STEPS THEN AN ATTEMPT IS MADE TO SUCCESSIVELY DOUBLE THE     | RDREB829 |
| C |     | STEP SIZE UNTIL EITHER THE MAX STEP SIZE OR AN UNACCEPTABLE  | RDREB830 |
| C |     | TRUNCATION ERROR IS REACHED. THE OPTIMUM STEP IS THEN        | RDREB831 |
| C |     | SELECTED FOR THE NEXT NOPT(2) STEPS. A TYPICAL VALUE FOR     | RDREB832 |
| C |     | NOPT(2) MAY BE 10. IF NO OPTIMIZATION IS REQUIRED THEN       | RDREB833 |
| C |     | NOPT(2) MAY BE SET TO A VALUE GREATER THAN THE MAX NUMBER    | RDREB834 |
| C |     | OF STEPS IN THE RUN, WHICH IS SPECIFIED AS NOPT(3). THE      | RDREB835 |
| C |     | MAXIMUM NUMBER OF STEPS SHOULD BE SELECTED ON THE BASIS OF   | RDREB836 |
| C |     | THE EXPECTED COMPUTING TIME PER STEP AND THE PERMISSIBLE     | RDREB837 |
| C |     | TIME LIMIT ON THE JOB. ADEQUATE ALLOWANCE MUST BE MADE IN    | RDREB838 |
| C |     | ORDER TO PREVENT -TIME LIMIT- ERROR, WHICH ON SOME SYSTEMS   | RDREB839 |
| C |     | MAY RESULT IN IMPROPER CLOSURE OF DATA FILES AND HENCE A     | RDREB840 |
| C |     | SUBSTANTIAL PORTION OF THE OUTPUT MAY BE LOST.               | RDREB841 |
| C |     |                                                              | RDREB842 |
| C | (6) | FOR MOST BEARINGS A TIME STEP SIZE OF ABOUT 10 MICROSECS     | RDREB843 |
| C |     | WILL BE ADEQUATE FOR CONVERGENCE TO WITHIN REASONABLE        | RDREB844 |
| C |     | TOLERANCE LIMITS. A TRIAL RUN WILL PRINT THE RELEVANT TIME   | RDREB845 |
| C |     | SCALE WHICH CAN BE USED TO ESTIMATE THE DIMENSIONLESS STEP   | RDREB846 |
| C |     | SIZE. THE MIN AND MAX STEP SIZES, SPECIFIED AS DMIN AND      | RDREB847 |
| C |     | DMAX RESPLY ON CARD 2, MAY BE ESTIMATED BY THE TRANSIENT     | RDREB848 |
| C |     | DETAILS REQUIRED IN THE SIMULATIONS. THE INITIAL STEP        | RDREB849 |
| C |     | SIZE, DINT, MUST BE BETWEEN DMIN AND DMAX. IF DINT=DMIN=     | RDREB850 |
| C |     | DMAX THEN NO STEP OPTIMIZATION WILL BE PERFORMED AND UNDER   | RDREB851 |
| C |     | SUCH A CONDITION NOPT(2) ON CARD 1 SHOULD BE SET EQUAL TO    | RDREB852 |
| C |     | A VALUE GREATER THAN THE MAX NUMBER OF STEPS IN THE RUN.     | RDREB853 |
| C |     |                                                              | RDREB854 |
| C |     |                                                              | RDREB855 |
| C |     |                                                              | RDREB856 |
| C |     |                                                              | RDREB857 |
