20. ABSTRACT (Continue on reverse side if necessary and identify by block number) Efforts toward the synthesis of polycyclic high density, high energy oxidizers have involved examination of synthetic paths to the hexaazaadamantane framework. Routes examined include condensation of amides with an orthoformate, reaction of tris(acylamino) methanes with orthoformate and cyclizations based on acylated perhydrotriazines. The cyclization chemistry of a pentaazabicyclo-nonadiene is also under investigation.

INTRODUCTION

The object of this program has been to synthesize and evaluate new high density, high energy, polycyclic nitramine/nitro containing oxidizers for solid propellant/explosive applications.

TECHNICAL DISCUSSION

A direct approach to the development of new high energy propellants with improved ballistic characteristics involves the design, synthesis, and development of new high energy oxidizers as HMX/RDX replacements. The ideal HMX/RDX alternative would incorporate many physical properties superior to HMX/RDX in addition to providing propellant compositions with much improved ballistic flexibility.

In considering compounds for potential use as new high energy oxidizers, we have selected organic compounds having a minimum of hydrogen (favors less water formation in propellant combustion products for minimum signature exhaust applications) and high -NO_2 functionality (favors high energy with a minimum loss in thermal stability). In addition, we propose to incorporate these features into symmetrical polycyclic structures. Such polycyclic structures incorporating energetic nitramine/nitro functionality are expected to yield the following improvements over presently available high energy oxidizers:

1. Increased energy
2. Increased density
3. Improved stability
4. Latitude in ballistic tailoring

Synthesis

Compound I, $\text{N}^1, \text{N}^2, \text{N}^3, \text{N}^4, \text{N}^5, \text{N}^6$ -hexanitro-2,4,6,8,9,10-hexaazadadamantane.

I

The hexaazaadamantane ring system remains unknown. We have examined several viable synthetic routes to the cage structure.

The direct synthesis (Scheme I) of a hexaazaadamantane starting from a number of different amides and a trialkyl orthoformate lead only to the corresponding tri(acylamino)methanes (2)¹ (Scheme II).

SCHEME I

SCHEME II

Attempts to force the reaction of Scheme I to the desired cage structure under conditions of higher temperatures and/or pressure lead only to unidentified black reaction mixtures. Similarly, reactions under forcing conditions using the tris(acylamino)methanes (2) as starting materials were unfruitful.

In an alternate route, (Scheme III) nitration of the tris(acylamino) methanes 2 followed by hydrolysis² was expected to lead to the unknown tris(nitramino)-methane 3, an interesting high energy substance in its own right. Reaction of 3 with an orthoformate may lead directly to 1.

Scheme III

However, attempted nitration of tris(acetamido)methane 2 ($R = -CH_3$) under standard conditions (nitric acid/acetic anhydride) resulted in complete destruction of starting material and the isolation of no organic products. We are presently attempting to follow this reaction by NMR in order to ascertain the course of the nitration.

A less direct route (Scheme IV) to acylated azaadamantane 1 was examined.

Reduction of aromatic rings including pyridines and pyrimidines via hydrogenation over rhodium or platinum catalysts is well known^{3,4}. However, reports of hydrogenation of triazine rings are lacking although saturation of the acylated melamine 4 under similar conditions in the presence of acetic anhydride to trap and stabilize the intermediate perhydrotriazine as acylated derivatives 5 appeared viable.

Attempts to hydrogenate triacetylmelamine 4 ($R = -CH_3$) to the desired saturated intermediate were frustrated by the pronounced insolubility of the compound.

SCHEME IV

Tripropionylmelamine (4, R = -C₂H₅) was successfully prepared in an attempt to secure a more soluble acylated melamine derivative for attempted catalytic hydrogenation of the triazine ring.

Unfortunately 4 (R = -C₂H₅) is not appreciably more soluble than the acetyl derivative. Consequently, hydrogenation at room temperature and 50 psi hydrogen over Rh-Pt catalyst resulted in no hydrogen uptake even after many days. High pressure and high temperature (up to 1200 psi, 185°C) hydrogenation conditions resulted in destruction of starting material and the production of dark colored amine smelling residues from which no identifiable materials have yet been isolated.

The bis-trifluoroacetate 6 of melamine was easily prepared and proved quite soluble in the desired acetic acid/acetic anhydride hydrogenation solvent.

However, even prolonged room temperature low pressure hydrogenation of 6 over Rh-Pt resulted again in no hydrogen uptake. Some evidence for the incorporation of acetyl group into the starting material (acetyl-trifluoroacetyl exchange?) was noted under these reaction conditions.

Subsequently it was found that tripropionyl melamine 4 ($R = -C_2H_5$) was soluble in warm trifluoroacetic acid/trifluoroacetic anhydride. However, prolonged low pressure hydrogenation of 4 ($R = -C_2H_5$) over Rh-Pt in this solvent system resulted again in no hydrogen uptake. This route to the hexaazaadamantane ring system has been abandoned.

In an alternate, new approach (Scheme V) we examined the construction of desired tricyclic azaadamantane system 7 from the available pentaazabicyclo(3.3.1)nonadiene 8 ($R = -H$).⁶

SCHEME V

Thus, addition of ammonia to one amidine linkage in 8 was expected to lead to 7 via cyclization of 9. Similar synthetic schemes have been used to prepare heteroadamantanes 10 starting from the carbocycle 11⁵.

However, from the onset, we were concerned that ammonia addition to bicyclic 8 would occur from the exo side by analogy with the well known chemistry of many carbobicyclic systems. The resulting stereochemistry would then, of course, be unfavorable for the desired cyclization to 7.

Indeed refluxing pentaazabicyclononadiene, prepared by the literature procedure⁶, with aqueous ammonia gave a mixture whose mass spectrum was characterized by a large peak at $M/z = 140$. Although the proton NMR of the reaction mixture consisted only of unresolved broad absorptions, the $M/z = 140$ peak was attributed to the formation of the exoamine adduct 12.

The proposed thermal and/or electron impact induced oxidation of the trisaminomethane functionality in 12 was thought consistent with the facile oxidation exhibited by a number of recently reported trisaminomethane derivatives.⁷

Consequently, we carried out a series of oxidation, reduction reactions designed to convert the presumed exo-adduct 12 into the desired endo adduct 13.

Oxidation of 12 with mercuric acetate⁸ followed by reduction with a limited amount of sodium cyanoborohydride was expected to lead to endo 13 via exo delivery of hydride to guanidine 14. Indeed examination of the proton NMR spectrum of the crude product (isolated as the picrate) after carrying out the indicated oxidation reduction sequence showed a sharp singlet (non-exchanging with D₂O) at 5.0 δ (acetone d₆) or 4.65 δ (DMSO-d₆). This observation was consistent with the formation of the desired hexaazaadamantane 7 via spontaneous cyclization of endo 13. The mass spectrum of the product was characterized by a strong peak at M/z 140 which, it was felt, was consistent with the desired product 7 via the following electron impact induced rearrangement/oxidation:

The ^{13}C NMR spectrum of the product showed one resonance at 72.7 ppm a somewhat higher field absorption than that expected for a trisaminomethane derivative. However, an off resonance decoupled ^{13}C NMR experiment showed conclusively that the unique carbon resonance at 72.7 ppm was attached to two hydrogens ($>\text{CH}_2$) clearly inconsistent with the desired polycycle 7.

Subsequently it was found that prolonged treatment of pentaazabicyclononadiene 8 with aqueous ammonia led directly to this unknown product. The substance was finally isolated and identified as the tetraazaadamantane 15 (hexamine).

Closer examination of the pentaazabicyclononadiene starting material as prepared by the literature method⁶ revealed that the material is apparently mostly polymeric with only trace quantities of the desired azabicyclic 8 present. Currently we believe hexamine (15) arises from ammonia reacting with formaldehyde supplied from this polymer mixture. Current studies are directed toward (1) attempted isolation of the pentaazabicyclononadiene from this literature reaction and (2) attempts to prepare 8 in a more pure form by alternate synthetic routes.

Compound II, N^1, N^2, N^3, N^4 -Tetranitro-2,4,6,8-tetraazatricyclo (3.3.0) octane ("Bicyclic HMX").

II

We have examined a number of synthetic routes to II. To date, direct reduction (Scheme VI) of either tetranitroglycoluril 16 or glycoluril 17 under a variety of conditions (BH_3/THF , $LiAlH_4$, diisobutylaluminum hydride, $NaBH_4/CF_3COOH$, etc.) to the desired bicyclic ring systems has proven unsuccessful.

SCHEME VI

However, in a model experiment, tetramethylglycoluril 18 ($R = -CH_3$) was successfully reduced to 19 ($R = -CH_3$).

Experiments were then undertaken to prepare analog 19 ($R = -CH(CH_3)_2$) which was expected to lead to II by dealkylative nitrolysis.⁹

Tetraisopropylglycoluril 18 ($R = CH(CH_3)_2$) has been successfully prepared, albeit in low yield, from diisopropylurea and glyoxal. Reduction with $LiAlH_4$ gave an oil the mass spectrum of which showed evidence for the presence of the desired intermediate 19 ($R = -CH(CH_3)_2$).

However, considerable work modifying reaction conditions and examination of a number of reducing agents has so far been unfruitful in enabling us to obtain sufficient quantities of 19 ($R = -CH(CH_3)_2$) for further experimentation. Attention was therefore directed toward alternate synthetic routes to the tetraazabicyclo (3.3.0) octane ring system. For example, the condensation of methylenediamine¹⁰ with glyoxal was examined in an attempt to construct directly the parent ring system.

Initial experiments have so far been unsuccessful although a similar condensation with ethylenediamine and glyoxal was used to prepare 20.¹¹

Further experimentation with this reaction sequence is underway. Also reaction of glyoxal with both methylenebisacetamide and methylene dinitramine² is being examined.

We have recently prepared tetranitraminoethane 21¹² and plan to examine its reaction with formaldehyde as an alternate condensation approach to II.

Theoretical Performance Calculations On New High Density, High Energy Polycyclic Oxidizers

Using estimated densities¹ and heats of formation^{2,3} theoretical performance calculations have been carried out for a number of our target polycyclic high energy oxidizers in several propellant formulations. The results of these calculations are tabulated and they show the considerable improvements in propellant Isp and propellant densities that are expected from the application of these new materials.

- 1) Estimated densities were calculated by the method of D. Cichra, J. Holder, and C. Dickinson, "Estimation of "Normal" Densities of Explosive Compounds from Empirical Atomic Volumes," NSWC Report TR 79-273, 12 February 1980.
- 2) Estimated heats of formation were calculated using a method developed by A. D. Little, Inc.,³ and extended by Thiokol/Wasatch with corrections applied for ring strain energies.⁴
