FOREWORD

This report is one of a series prepared for the Department of the Air Force, Ballistic Missile Office (BMO), in compliance with Contract No. F04704-80-C-0006, CDRL Item No. 004A2. These reports present the results of Detailed Aggregate Resources Studies within and adjacent to selected areas in Nevada and Utah that are under consideration for siting the MX missile system.

This volume contains the results of the aggregate resources evaluation for Pine Valley. Results of this report are presented as text, appendices, and three drawings. This report has been prepared and submitted on the assumption that the reader is familiar with previous aggregate resources reports.

EXECUTIVE SUMMARY

This report contains the Detailed Aggregate Resources Study (DARS) evaluation for Pine Valley, Utah. It is the fifth in a series of reports that contain detailed aggregate information on the location and quality of basin-fill and rock sources of road-base and concrete aggregates. Field reconnaissance, laboratory testing, and existing data from other Ertec Western, Inc. (formerly Fugro National, Inc.) investigations and the Utah State Department of Highways provide the basis for the findings presented in this report.

ROAD-BASE AGGREGATES

Potential road-base aggregate sources were classified as follows:

- Class RB1a - Basin-fill or rock sources containing materials suitable for use as road-base aggregates; based on acceptable laboratory aggregate test results.
- Class RB1b - Basin-fill sources containing materials suitable for use as road-base aggregates; based on correlation with Class RB1a source areas.
- Class RBII - Potential basin-fill sources of materials suitable for use as road-base aggregates; based on photogeologic interpretations, field observations, and limited or inconclusive sieve analysis and/or abrasion data.

Assignment of an aggregate source to one of the above three classes was determined from laboratory test results (gradation, abrasion and, to a lesser extent, soundness) and geomorphological and compositional correlations.

Results of this evaluation are presented on a 1:62,500 scale aggregate resources map (Drawing 2) and are summarized as follows:

Class RB1a Sources: Twelve basin-fill sources consisting of good- to high-quality aggregates acceptable for use as road-base construction materials have been located in the valley. The 11 most extensive deposits are alluvial fans (Aaf). Most of the sources are located on the east side of the valley.

Five crushed-rock sources which yielded good- to high-quality aggregates acceptable for use as road-base construction materials have been delineated within the study area. These sources include outcrops of quartzite (Qtz), limestone (Ls), and undifferentiated carbonate rocks (Cau).

Class RB1b Sources: Eleven basin-fill deposits within the study area are defined as potential sources of good- to high-quality, road-base aggregates. Geomorphological and compositional similarities were used to correlate these units to tested RB1a deposits. Deposits are all alluvial fans generally confined to the east side of the valley.

Class RB1I Sources: Several potential basin-fill aggregate sources are located throughout the study area. All of these sources are alluvial fans that have been classified on the basis of limited field and laboratory data.

CONCRETE AGGREGATES

A classification system consisting of five classes was developed for the concrete aggregates evaluation to present potential basin-fill and crushed-rock sources. Although most rock sources will supply coarse concrete aggregates, their delineation was not an objective of this study. Assignment of an aggregate source to one of the five classes was determined from laboratory test results (trial concrete mixes and gradation, abrasion, and

soundness of aggregates) and geomorphological and compositional correlations. The emphasis of this study was the evaluation of the concrete-making properties (especially 28-day compressive strengths) of potential aggregates when used in trial concrete mixes.

- Class CA1 Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths equal to or greater than 6500 psi.
- Class CA2 Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths less than 6500 psi.
- Class CB Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on acceptable laboratory aggregate test results.
- Class CC1 Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on correlation with Class CA1 and CA2 source areas.
- Class CC2 Basin-fill sources containing aggregates potentially suitable for use in concrete; based on correlation with Class CB source areas.

The following three trial mixes were used to obtain a range of compressive strength values; however, only Mix 3 results were used to classify sources. In all three trial mixes, fly ash, as a pozzolan, replaced 20 percent of the cement by weight.

- o Mix 1 - 7.5 sacks of cement per cubic yard of concrete and 1.5-inches maximum aggregate size;
- o Mix 2 - 8.5 sacks of cement per cubic yard of concrete and 1.5-inches maximum aggregate size; and
- o Mix 3 - 8.5 sacks of cement per cubic yard of concrete, 0.75-inch maximum aggregate size, and a superplasticizer.

Results of this evaluation are presented on a 1:62,500 scale aggregate resources map (Drawing 3) and summarized as follows:

Class CA1 and

Class CA2 Sources: One basin-fill deposit in the area contained aggregates that, when used in Mix 3, produced 28-day compressive strengths greater than 6500 psi. This source is an alluvial fan (Aaf) located on the east side of the valley.

Crushed-rock aggregates from two rock sources in the study area produced 28-day compressive strengths in excess of 6500 psi. These rock sources consist of undifferentiated carbonate rocks (Cau) and quartzite (Qtz). Fine aggregates used in conjunction with crushed rock in these concrete mixes passed magnesium sulfate soundness tests.

One basin-fill deposit in the area contained aggregates that, when used in Mix 3, produced 28-day compressive strengths less than 6500 psi. This source is an alluvial fan located on the east side of the valley.

Sufficient quantities of fair to satisfactory quality fine aggregates are available in most basin-fill deposits. High-quality, fine aggregate sources are of limited extent within the study area.

Class CB Sources: Eleven basin-fill deposits consisting of good- to high-quality aggregates, potentially acceptable for use as sources of concrete construction materials, were delineated in the valley. All but one of these deposits are alluvial fans.

Class CC1 Sources: Two alluvial fans in the study area are classified as potential sources of concrete aggregates. They are correlated to Class CA1 and CA2 sources based on geomorphological and compositional similarities.

Class CC2 Sources: Several basin-fill units located throughout the valley are potential sources of aggregates suitable for use in concrete. They are correlated to Class CB units on the basis of geomorphological and compositional similarities.

CONCLUSIONS

Sufficient quantities of coarse and fine aggregates suitable for use as road-base and/or concrete-construction material are available in Pine Valley. Laboratory test results indicate that the quality of the coarse aggregates ranges from good to excellent and the quality of the fine aggregates ranges from fair to satisfactory. Most of the aggregate sources are confined to the eastern and southern portions of the valley.

RECOMMENDATIONS

Additional aggregate field investigations and laboratory testing will be required to further refine the physical and chemical characteristics of road-base and concrete aggregate sources as borrow areas prior to the initiation of construction.

1.0 INTRODUCTION

1.1 STUDY AREA

This report presents the results of the Detailed Aggregate Resources Study (DARS) for Pine Valley (Figure 1). Pine Valley is located in southern Millard and northern Beaver counties, Utah. It is bounded on the west by the Indian Peak and The Needles ranges and by the Desert Range Experimental Station and on the east by the Wah Wah Mountains. The valley is topographically open to Snake Valley to the north. Highway 21 is the only paved road in the vicinity. A network of graded roads and four-wheel-drive trails provide access to most parts of the study area. Pine Valley is mainly undeveloped desert rangeland administered by the Bureau of Land Management (BLM). The Desert Range Experimental Station is managed by the State of Utah. Several active mining operations are located in the Wah Wah Mountains. Milford, Utah, is located approximately 36 miles (58 km) east of Pine Valley on Highway 21.

1.2 BACKGROUND

Aggregate resources studies for the MX program were introduced in 1977 with the investigation of Department of Defense (DoD) and BLM lands in California, Nevada, Arizona, New Mexico, and Texas (FN-TR-20D). Refinement of the MX siting area added portions of Utah and Nevada that were not evaluated in this initial Aggregate Resources Evaluation Investigation (AREI). This additional area, defined as the Utah-Nevada aggregate resources study area, was examined in the fall of 1979 and a

second regional aggregate resources report (FN-TR-34) was submitted on 3 March 1980 (Figure 2).

Both regional aggregate investigations consisted of the compilation and evaluation of existing data with limited field reconnaissance, sample collection, and laboratory aggregate testing. Only general information on the location, quality, and quantity of aggregates was provided.

Subsequent to the regional studies, Valley-Specific Aggregate Resources Studies (VSARS) were started in FY 79. The primary objective of these continuing studies is to provide additional information on potential aggregate sources in specified valleys and in the areas immediately surrounding them. Existing exposures of potential basin-fill and rock aggregate sources are sampled and subjected to a suite of laboratory tests. Results of these tests are used to classify coarse and fine basin-fill and crushed-rock aggregates for suitability as concrete and road-base construction materials.

The aggregate sources presented in the VSARS are to be used as a guide for preliminary construction planning and the selection of areas for more detailed-aggregate evaluations. To date, field investigations have been completed for 16 valley areas with final reports submitted for 11 valley areas (Figure 3). Field investigations for remaining valleys in the designated deployment area are planned in FY 81 and FY 82.

The DARS were initiated in FY 81 to further analyze and refine potential sources of coarse and fine basin-fill and crushed-rock

aggregates identified during the VSARS. These studies consist of both road-base (Section 3.0) and concrete (Section 4.0) aggregate evaluations. The major consideration was to further evaluate basin-fill deposits as potential sources of road-base and concrete aggregates. Limited new data were developed on crushed-rock sources.

1.3 OBJECTIVES

The objectives of the Detailed Aggregate Resources Study are as follows:

Road-Base Aggregates Evaluation

- o Refine potential basin-fill and rock sources (initially identified in VSARS) for road-base aggregates; and
- o Provide additional laboratory test data on the general quality of basin-fill aggregates for use as road-base material.

Concrete Aggregates Evaluation

- o Refine the areal extent of the most acceptable VSARS basin-fill and rock concrete aggregate sources; and
- o Provide additional laboratory testing information on the quality and the concrete-making properties of potential coarse and fine, basin-fill and crushed-rock aggregates.

1.4 SCOPE

The scope of the two evaluations required office and field studies and included the following:

- a. Compilation and analysis of appropriate existing data on the quality and quantity of potential road-base and concrete aggregates. Major sources of data were other Ertec investigations for the siting of the MX system and the Utah State Department of Highways.
- b. Initial and final basin-fill deposit differentiation based on geomorphology, grain size, lithology, and aerial-photograph and topographic-map interpretation. Initial and

final rock unit divisions based on evaluations of aerial photographs and published geologic maps.

- c. Staking and permitting on selected BLM lands. Appropriate basin-fill trench locations for samples of road-base and concrete aggregates were determined from items a and b and a brief field reconnaissance.
- d. Backhoe excavation of staked and permitted basin-fill locations, sampling when gravel percentage exceeded 30 percent, or when suitable fine aggregates for concrete mixes were present. Selection and sampling of acceptable crushed-rock sources of coarse aggregates for concrete mixes.
- e. Valley-wide field reconnaissance utilizing aerial photographs and petrographic and grain-size analyses to determine lateral extent and acceptability of basin-fill deposits.
- f. Laboratory tests to supplement available existing data for the determination of the suitability of specific basin-fill and rock units as sources of road-base or concrete aggregates. Trial (check) concrete mixes were made to evaluate the basic concrete-making properties of selected concrete aggregate sources as well as engineering properties of hardened concrete.
- g. Development and application of road-base and concrete materials classification systems that textually and graphically depict the locations of the most suitable aggregate sources in the study area. The depiction and discussion of areas that are unsuitable or have a low probability for use were not done.

2.0 GEOLOGIC SETTING

2.1 PHYSIOGRAPHY

Pine Valley lies within the Basin and Range Physiographic Province and exhibits characteristic north-south trending, block-faulted mountain ranges with an intervening alluvial basin. Elevations range from about 6800 feet (2073 m) in the east-central part of the valley to 5075 feet (1547 m) on the playa in the northern part of the valley.

Mountain ranges flanking the basin are the Wah Wah Mountains to the east, the Indian Peak Range to the south and southwest, and The Needles Range, Tunnel Spring Mountains, and Middle Mountain to the west. Pine Valley is contiguous to Snake Valley to the north through a narrow pass between the Tunnel Spring Mountains and Middle Mountain. Topographic relief between mountain ridges and the basin floor ranges from about 3120 feet (951 m) to 2140 feet (652 m) in the Wah Wah Mountains, about 1265 feet (386 m) in The Needles Range, and about 1100 feet (335 m) in the Indian Peak Range. Pine Valley has a closed drainage system to the Pine Valley Hardpan except for the extreme southern part of the valley which drains south to the Escalante Desert area.

2.2 LOCATION AND DESCRIPTION OF GEOLOGIC UNITS

Paleozoic and Cenozoic rocks are found in bedrock outliers within the valley and in the mountains in and adjacent to the study area. The Paleozoic rocks consist predominantly of limestone, dolomite, and quartzite with interbedded sandstone and shale. These units crop out along the margins of the entire study area.

Unconformably overlying the Paleozoic rocks are Cenozoic rocks consisting predominantly of undifferentiated Tertiary volcanic and intravolcanic sedimentary rocks. Unconsolidated Cenozoic deposits lie unconformably above all older units and consist primarily of alluvial, lacustrine, and stream-channel and terrace deposits.

Specific Paleozoic and Cenozoic geologic units have been grouped into three rock and three basin-fill categories for use in discussing potential aggregate sources. The grouping of the units was based on similarities in physical and chemical characteristics and map-scale limitations. The resulting categories simplify discussion and presentation without altering the conclusions of the study.

Additional geologic information is presented in previous Ertec reports (FN-TR-37-g; and FN-TR-27-PI-I and II).

2.2.1 Rock Units

Geologic rock units that are potential sources of crushed-rock aggregates are grouped into the following three categories: quartzite (Qtz), limestone (Ls), and carbonate rocks undifferentiated (Cau). While other rock units may locally supply aggregates, they are not considered major sources and will not be discussed in this report.

2.2.1.1 Quartzite - Qtz

Two quartzite rock units (Qtz) are present in the study area. They are the Cambrian Prospect Mountain Quartzite and the Ordovician Eureka Quartzite.

The Cambrian Prospect Mountain Quartzite crops out in the Wah Wah Mountains and is found as outliers adjacent to the Wah Wah Mountains. This unit consists of thin- to thick-bedded, fine- to medium-grained, pinkish-gray to reddish-brown orthoquartzite with interbedded sandstone, micaceous shale, and conglomerate.

The Ordovician Eureka Quartzite is exposed primarily in the central Needles Range and southern Tunnel Spring Mountains. The Eureka Quartzite consists of thin- to thick-bedded, fine- to medium-grained, light-brown to white orthoquartzite with interbedded sandstone and shale near the base and top of the unit.

2.2.1.2 Limestone - Ls

Units mapped as limestone (Ls) include the Cambrian Marjum Formation and the upper white marker bed of the Weeks Formation. These units are located in the Wah Wah Mountains. They are typically thin- to thick-bedded, fine- to coarse-grained, light- to dark-gray limestone with interbedded chert, sandstone, siltstone, and shale.

2.2.1.3 Carbonate Rocks Undifferentiated - Cau

The single unit mapped as undifferentiated carbonate rocks (Cau) is the Cambrian Wheeler Formation, occurring in the Wah Wah Mountains. The lithology of this unit varies considerably; however, it is typically medium- to thick-bedded, fine- to medium-grained, medium- to dark-gray dolomite, limestone, and locally dolomitic limestone with interbedded clastic rocks and chert.

2.2.2 Basin-fill Units

The basin-fill units within the study area that are potential sources of coarse and fine aggregates are alluvial fan deposits (Aaf), stream-channel and terrace deposits (Aal), and older lacustrine deposits (Aol). The grouping of the units was based on similarities in physical and chemical characteristics and map-scale limitations. All other basin-fill units may locally supply aggregates but are not considered major sources and will not be discussed in this report.

2.2.2.1 Alluvial Fan Deposits - Aaf

Alluvial fans deposits (Aaf) are the most extensive potential sources of basin-fill aggregates within the study area. They occur as a narrow band along most of the eastern and southern sides of the study area and as isolated deposits on the west side of the valley and along the eastern and southern boundaries of the Desert Range Experimental Station. Alluvial fan deposits are typically heterogeneous to poorly stratified mixtures of boulders, cobbles, gravel, sand, silt, and clay.

Fans derived from quartzite and carbonate rock sources are coarser grained and contain many cobbles and boulders. Fans derived from volcanic rock sources are predominantly fine gravel and sand.

Most alluvial fan deposits have developed soil horizons consisting of silty, clayey sand a few inches to 1 foot (0.3 m) in thickness overlying a zone of carbonate accumulation (caliche). The caliche horizon generally ranges in thickness from 1 to

3 feet (0.3 to 1 m) and exhibits Stage I to III development with Stage II to III being most common (Appendix F).

2.2.2.2 Stream Channel and Terrace Deposits - Aal

Stream-channel and terrace deposits (Aal) in the study area are associated with ephemeral streams within the valley. They range in composition from sandy gravel and gravelly sand near the mountain fronts to sandy silt near the valley axis. The greatest concentration of major stream-channel and terrace deposits is in the southern portion of the study area. Although other deposits were identified during the VSARS as potential aggregate sources, only one was delineated during this investigation. Caliche development within the stream-channel deposits ranges from absent to incipient Stage I.

2.2.2.3 Older Lacustrine Deposits - Aol

Older lacustrine deposits (Aol) in Pine Valley were formed by Pleistocene Lake Wah Wah. The elevation of the highest lake level for Lake Wah Wah is unknown. Shoreline bar deposits north of the Pine Valley Hardpan are evidence that there was a shoreline at approximately 5200 feet (1585 m). Older lacustrine shoreline bar deposits are typically poorly graded, moderately stratified sand. Caliche is present as coatings on the gravel and sand particles.

3.0 ROAD-BASE AGGREGATES EVALUATION

3.1 STUDY APPROACH

The primary objective of the road-base aggregate study was to evaluate the suitability of basin-fill and rock aggregates for use as road base. Two important considerations were applied to basin-fill aggregate sources identified as potentially suitable in VSARS; refinement of source boundaries, and additional laboratory tests to further evaluate physical and chemical characteristics. Sources of crushed-rock aggregates were refined using only existing data, published geologic maps, and limited photogeologic interpretations. Information on potential rock sources for use as road-base aggregates was not specifically collected for this evaluation. Only existing VSARS data and data developed from the concrete aggregates evaluation (Section 4.0) were assessed.

The study approach for the road-base aggregates evaluation required a review of previous Ertec Verification (FN-TR-27-PI-I and II) and aggregate reports (FN-TR-34 and FN-TR-37-g) for Pine Valley. This data base helped define the scope of the road-base materials investigation which included office and field photogeologic and topographic interpretations, field reconnaissance, and collection and laboratory testing of basin-fill samples.

3.1.1 Requirements for Road-Base Aggregates

For the purpose of this report, road-base aggregates are defined using the Nevada Department of Highways (1976) classification of

Type I Class A aggregate base. The requirements for aggregates suitable for such a base are as follows:

Gradation:

<u>Sieve Size</u>	<u>Percent Passing by Weight</u>
1.5 inches	100
1.0 inch	80-100
No. 4	30- 65
No. 16	15- 40
No. 200	2- 12
Fractured Faces	35 percent, minimum
Plasticity Index	3-15 percent
Liquid Limit	35 maximum
Resistance (R value)	70 minimum
Percent Wear (500 Rev.)	45 percent, maximum

During the road-base aggregate studies, gradation and percent wear were the two primary criteria used to evaluate potential source areas. Magnesium sulfate ($MgSO_4$) soundness tests were performed on selected aggregate samples to gain additional information related to the effects of weathering on aggregates. Soundness losses exceeding 18 percent were considered potentially unacceptable (American Society of Testing and Materials, 1978). The remaining requirements were not evaluated during this study.

3.1.2 Data Acquisition and Analysis

Office studies for the road-base aggregates evaluation required preliminary basin-fill and rock-unit differentiation based on photogeologic interpretations and published topographic and geologic maps. All available data on basin-fill, grain-size gradations were compiled to estimate gravel content for the defined basin-fill units.

The field program involved backhoe excavation of 58 trenches selected during office studies and initial field reconnaissance. Trenches were excavated and sampled in groups of two or three, 0.1 to 0.2 mile (0.2 to 0.3 km) apart, or groups of five, 150 feet (46 m) apart, to characterize individual basin-fill units. Completion depths ranged from 12 to 15 feet (3.7 to 4.6 m) and, where collected, representative samples averaged 100 pounds (45 kg) per trench.

Due to gradation variability in basin-fill deposits, field limits of 30 percent or more gravel and 20 percent or less silt and clay were established as basic aggregate grain-size distribution requirements. Gravel is defined as coarse aggregates which pass the 3.0-inch (75-mm) sieve and are predominantly retained on a No. 4 (4.75-mm) sieve. Aggregates larger than 3.0 inches (cobbles and boulders) were generally present in the materials investigated but were not included in the laboratory samples because of sample-size limitations. Silt and clay particles are defined as material passing through a No. 200 sieve (0.0029-inch [0.075-mm]).

Field studies also included 46 petrographic and grain-size data field stops and valley-wide photogeologic field reconnaissance. These analyses were performed to supplement and confirm office studies and to provide a data base for lithologic and gradation correlations of basin-fill units.

Laboratory testing that included 63 sieve analyses, 15 abrasion tests, and eight MgSO_4 soundness tests was performed to broaden

the existing data base during the road-base aggregates evaluation. Confirmation test data (gradation, abrasion, and soundness tests) from the concrete aggregates evaluation (Section 4.0) were also used to supplement test data for the road-base aggregates evaluation.

The scope of the study did not allow sample collection and laboratory testing of all potential road-base aggregate sources. Existing data and field petrographic and grain-size analyses were used to correlate lithologic and gradation properties to basin-fill units which were not sampled. An important element of this correlation procedure was the use of aerial photographs to help delineate the lateral extent of basin-fill deposits. Photogeologic and field observations ascertained geomorphological and topographical relationships of basin-fill units and the source rock lithology and distribution of predominantly gravelly materials.

3.1.3 Presentation of Results

Results of the road-base aggregates evaluation are presented in the form of text, figures, 1:62,500 scale drawings, and appendices. Drawing 1 shows the locations of all the data points used in the Detailed Aggregate Resources Study. The data points are grouped by study type and assigned categorized map numbers. VSARS data points are designated by map numbers 1 to 199 and correspond to map numbers in the appendix table of the Pine area VSARS report (FN-TR-37-g). DARS data points are assigned map number groups 200 to 299 for trench locations and 300 to 399

for petrographic and grain-size data stop locations. Verification data points are assigned the map number group 400 to 599. For direct reference, appendix Table G-1 converts map number to Pine Verification Report (FN-TR-27-PI-I and II) activity type and number.

Drawing 2 presents the locations of all potential road-base aggregate sources, DARS trenches, DARS field petrographic and grain-size data stops, and selected VSARS data stops in the study area. Geologic unit symbols used in Drawing 2 relate to standard geologic nomenclature whenever possible. A conversion table relating these symbols to the geologic unit nomenclature used in other Ertec reports is contained in Appendix Table F-3.

A solid contact line separates basin-fill and rock units in Drawing 2 to differentiate these two basic material types. All rock contacts are from published data or limited air-photo interpretation and are dashed. Basin-fill contacts are derived from photogeological mapping with limited field reconnaissance and are also dashed.

Classifications of potential sources of basin-fill and crushed-rock road-base aggregates are distinguished by different patterns. Patterns for basin-fill and rock sources of the same classification are similar, with the basin-fill pattern emphasized by a dark background tone.

The appendices contain tables that summarize the basic field data collected during the course of the study and the subsequent

laboratory test procedures and results. Appendices A and B include DARS trench data and petrographic and grain-size analysis data, respectively. Appendix C contains representative trench logs. Appendix Table D-1 presents a laboratory testing flow diagram for the road-base aggregates evaluation. Appendix F includes three tables describing soil classification, caliche development, and geologic unit cross reference.

3.1.4 Classification of Road-Base Aggregates

A classification system was designed to present the most likely locations of potential sources of basin-fill and crushed-rock road-base aggregates. It was developed from an evaluation as well as from an extrapolation of all available data.

This classification system is primarily based on laboratory test results (gradation and abrasion and, to a lesser extent, soundness) and geomorphological and compositional correlations. The classification is presented in hierarchy form; classification of the highest potential source areas is described first and classification of the lowest potential source areas is described last.

<u>Class</u>	<u>Explanation</u>
RB1a	Basin-fill or rock sources containing materials suitable for use as road-base aggregates; based on acceptable laboratory aggregate test results.

Class RB1a includes those source areas where the potential for suitable road-base aggregates is the highest. Each delineated

area has been sampled and tested. In order to assign Class RB1a to a basin-fill deposit, the source must satisfy the overall requirements outlined in Section 3.1.1.

<u>Class</u>	<u>Explanation</u>
RB1b	Basin-fill sources containing materials suitable for use as road-base aggregates; based on correlation with Class RB1a source areas.

Class RB1b basin-fill deposits are correlated to tested RB1a deposits on the basis of limited laboratory sieve analysis data and field observations. Field observations included petrographic and grain-size analyses which provided data on lithology of adjacent source rock and general amounts and lithologies of gravel present in the basin-fill units. Photogeologic interpretations were also used to correlate Class RB1b deposits to RB1a deposits. Specific geomorphological parameters included surface texture, drainage patterns, relative relief, and topographic profiles.

<u>Class</u>	<u>Explanation</u>
RBII	Potential basin-fill sources of materials suitable for use as road-base aggregates; based on photogeologic interpretations, field observations, and limited or inconclusive sieve analysis and/or abrasion data.

Class RBII includes poorly defined basin-fill aggregate sources. Field observations and inconclusive field and laboratory data indicate these deposits may be potentially acceptable for use as road-base aggregate sources.

All classifications are based on limited data. Additional field reconnaissance, testing, and case history studies are needed to confirm adequacy, delimit exact areal boundaries, and refine chemical and physical characteristics.

3.2 SOURCES OF ROAD-BASE AGGREGATES

The potential basin-fill and rock sources defined for use as road-base aggregates in the Pine Valley study area include alluvial fan deposits (Aaf), a stream-channel and terrace deposit (Aal), and quartzite (Qtz), limestone (Ls), and undifferentiated carbonate rock (Cau).

3.2.1 Basin-Fill Sources

All three classes of road-base aggregates, Class RB1a, RB1b, and RB1I, are present in the basin-fill deposits of Pine Valley (Drawing 2).

3.2.1.1 Class RB1a

The majority of the Class RB1a sources within the study area are located along the eastern margin of the valley adjacent to the Wah Wah Mountains. Other Class RB1a sources are located on the west side of the study area adjacent to the Indian Peak and The Needles ranges and the eastern and southern boundaries of the Desert Range Experimental Station.

There are 12 Class RB1a basin-fill sources within the study area; 11 are alluvial fan deposits (Aaf) and one is a stream-channel deposit (Aal). Although alluvial fans commonly exhibit a greater degree of caliche development (Stage II and III),

there are no significant compositional or lithological differences between the stream-channel and the alluvial fan units. These basin-fill sources generally consist of poorly to well-graded, subangular to subrounded sandy gravel. The gravel content of these sources ranges from a low of 42 percent to a high of 72 percent, but most deposits contain between 55 and 63 percent gravel. The sand content ranges from a low of 21 percent to a high of 53 percent. The sands are evenly distributed among all appropriate sieve sizes. Silt and clay content (below the overburden layer) ranges from a low of four percent to a high of 18 percent, but most deposits range from six to eleven percent.

Class RB1a basin-fill sources north of Highway 21 consist of carbonates with lesser amounts of quartzite. Sources in the southern portions of the valley, adjacent to the Indian Peak Range and the southern Wah Wah Mountains, consist of volcanic clasts. Sources consisting of quartzite with lesser amounts of carbonates are located immediately south of Highway 21 adjacent to the Wah Wah Mountains. Adjacent to The Needles Range, there are local concentrations of volcanic, carbonate, and quartzite clasts.

The gradation of Class RB1a sources approximates the grain-size distribution requirements stated in Section 3.1.1 (Figure 4). Class RB1a deposits generally share the same gradation characteristics; some cobbles and coarse gravels (oversize material) are present, gravels passing the 1.5- to 0.75-inch sieves are generally deficient, and all other grain sizes, from fine gravel

FIGURE 4

to fine sand, conform or nearly conform to design gradation requirements. Material greater than 2 inches can be crushed to produce additional aggregates of all sizes. Additional minor processing of all RB1a deposits will be necessary to conform to the gradation requirements.

It has been observed that variations in grain-size gradations occur within a source depending on sample location. In general, gradations within a source are finer near the valley axis and coarser near mountain fronts. Due to access restrictions, samples were generally collected at distal and medial locations within each deposit.

Laboratory abrasion tests performed on samples from all Class RB1a sources have a narrow range of 21.7 to 32.3 percent wear. Laboratory $MgSO_4$ soundness tests performed on a selected group of Class RB1a sources yielded results ranging from 1.9 to 4.3 percent loss for coarse aggregates and from 10.4 to 15.7 percent loss for fine aggregates. These results are generally within the acceptable values for abrasion and soundness.

The areal extent of individual Class RB1a sources ranges from approximately 0.6 to 22.0 mi^2 (1.6 to 57.0 km^2). Excluding the variable stream-channel unit the thickness of these Class RB1a sources has been estimated to be at least 25 feet (7.6 m). Generally, 75 to 90 percent of the material in these deposits will be suitable for use as road-base aggregates.

3.2.1.2 Class RB1b

Class RB1b basin-fill sources consist of 11 alluvial fan (Aaf) deposits that have been correlated to Class RB1a sources and, therefore, are considered to contain material acceptable for use as road-base aggregates. These sources occur on the east side of the valley adjacent to the Wah Wah Mountains, on the west side of the valley adjacent to The Needles Range, and as a small source on the eastern border of the Desert Range Experimental Station. Class RB1b basin-fill sources are generally adjacent to Class RB1a sources.

Since Class RB1b basin-fill sources are correlated to Class RB1a sources, they possess the same general characteristics as the RB1a sources; poorly to well-graded, subangular to subrounded sandy gravel consisting predominantly of carbonate and quartzite clasts with minor amounts of volcanic clasts.

Although variations in grain-size gradations will occur, depending on sample location within the deposit and the proximity of the deposit to its source area, Class RB1b sources are interpreted to have gradation distributions and yields similar to RB1a sources. The areal extent of the RB1b deposits ranges from 0.2 to 8.3 mi² (.5 to 21.5 km²).

3.2.1.3 Class RB1I

Class RB1I basin-fill aggregate sources are alluvial fan deposits that are potentially acceptable for use as road base. These deposits have been classified on the basis of limited field and laboratory data collected during this and other Ertec studies.

Class RBII consists of nine widely spaced deposits located adjacent to the east and west flanks of Middle Mountain, along the east side of the study area adjacent to the Wah Wah Mountains, and on the west side of the valley adjacent to The Needles and Indian Peak ranges.

Limited laboratory and field data were used to define the Class RBII sources. They are composed predominantly of sandy gravel and gravelly sand with appreciable amounts of carbonate, quartzite, and volcanic clasts. The areal extent of individual RBII deposits ranges from approximately 0.3 to 33 mi² (0.8 to 85.5 km²).

3.2.2 Rock Sources

The study approach used to evaluate road-base aggregates emphasized the analysis of basin-fill deposits and dictated that only previously tested crushed-rock sources be discussed and classified (Drawing 2). As a consequence, other rock units potentially suitable as sources of crushed-rock, road-base aggregates are not included or described in this study.

Class RB1a sources of crushed rock for use as road-base aggregates include quartzite (Qtz), limestone (Ls), and undifferentiated carbonate rocks (Cau). These sources are located at five widely spaced locations within the study area. On the east side of the valley, four Class RB1a crushed-rock sources are located in the Wah Wah Mountains north and south of Highway 21. On the west side of the valley, one Class RB1a crushed-rock

source is located in The Needles Range, 3 miles south of latitude 38° 30' N.

Results of laboratory abrasion tests performed on samples from the Class RB1a crushed-rock samples ranged from 20.1 to 32.9 percent wear. Laboratory MgSO_4 soundness test results range from 0.2 to 9.2 percent loss. These test results are well within the acceptable ranges for road-base aggregates.

4.0 CONCRETE AGGREGATES EVALUATION

4.1 STUDY APPROACH

The purpose of the concrete aggregates evaluation is to determine the suitability of aggregates within Pine Valley for use in concrete. To accomplish this, two objectives have been established:

- o Evaluate the basic physical and chemical characteristics of the aggregates; and
- o Determine the concrete making properties of the aggregates.

The study approach required to achieve these objectives included a review of previous Ertec Verification (FN-TR-27-PI-I and II) and aggregate reports (FN-TR-34 and FN-TR-37-g). This data base helped define the scope of the concrete aggregates investigation and included office and field photogeologic and topographic interpretations, field reconnaissance, and collection and laboratory testing of basin-fill and rock samples.

4.1.1 Requirements for Concrete Aggregates

The following requirements for aggregates and concrete (made using these aggregates) were established using criteria from the American Society of Testing and Materials (1979), the "Concrete Manual" prepared by the United States Department of the Interior (1975), and from Milos Polivka (1981, personal communication).

1. Aggregates

- o Gradation - The aggregate gradation specifications used by the American Society of Testing and Materials (1979, C 33) were selected to evaluate the samples tested. These grading specifications follow.

Coarse Aggregates

<u>Sieve Size</u>	<u>Percent Passing by Weight</u>	<u>Sieve Size</u>	<u>Percent Passing by Weight</u>
2 inches	100	1 inch	100
1.5 inches	95-100	0.75 inch	90-100
1 inch	---	0.5 inch	---
0.75 inch	35-70	0.375 inch	20-55
0.50 inch	---	No. 4	0-10
0.375 inch	10-30	No. 8	0-5
No. 4	0-5		

Fine Aggregates

<u>Sieve Size</u>	<u>Percent Passing by Weight</u>
0.375 inch	100
No. 4	95-100
No. 8	80-100
No. 16	50-85
No. 30	25-60
No. 50	10-30
No. 100	2-10
No. 200	

- o Abrasion - Los Angeles Machine abrasion losses for coarse aggregates are not to exceed 50 percent.
- o Soundness - Five-cycle magnesium sulfate (MgSO_4) soundness losses are not to exceed 18 percent and 15 percent for coarse and fine aggregates, respectively. Although not a requirement for the evaluation, five-cycle sodium sulfate (NaSO_4) soundness tests are performed on samples that failed MgSO_4 testing. Resultant losses are not to exceed 12 percent and 10 percent for coarse and fine aggregates, respectively.
- o Reactivity - Aggregates are to be nonreactive to alkali-silica and alkali-carbonate rock tests. Results are incomplete and will be submitted as an addendum to this report.

2. Concrete

- o Compressive Strength - The primary concrete requirement is a 28-day compressive strength equal to or greater than 6500 psi.
- o Static Modulus of Elasticity - Values of 3 to 6 million psi at 28 days required.

- o Splitting Tensile Strength - Ten percent or less of the compressive strength value at 28 days required.
- o Ultimate drying shrinkage - Values of 0.03 to 0.10 percent (300 to 1000 millionths) required.

4.1.2 Data Acquisition and Analysis

4.1.2.1 Office Studies

Office studies for the concrete aggregates evaluation required preliminary basin-fill and rock-unit differentiation based upon photogeologic interpretations and published topographic and geologic maps. All available data on basin-fill, grain-size gradations were compiled to estimate gravel content for the defined basin-fill units. All available test data on the aggregate properties of basin-fill and rock units were compiled to select sample locations in units previously tested and found preliminarily acceptable for use as concrete aggregate sources.

4.1.2.2 Field Studies

The field program involved backhoe excavation of 11 trenches selected during office studies and initial field reconnaissance; 10 trenches were excavated to obtain samples of coarse and fine aggregates (gravel and sand), and one was excavated to obtain samples of fine aggregates (sand).

Due to gradation variability in basin-fill deposits, field limits of 30 percent or more gravel and 15 percent or less silt and clay were established as basic aggregate grain-size distribution requirements. Gravel is defined as coarse aggregates which pass the 3.0-inch (75-mm) sieve and are predominantly retained on a No. 4 (4.75-mm) sieve. Silt and clay particles are defined

as material passing through a No. 200 sieve (0.0029-inch [0.075-mm]).

The 10 trenches excavated to collect basin-fill samples for concrete aggregate evaluations were grouped into two sets of five (150 feet apart [46 m]) to characterize individual basin-fill units. A single trench was excavated to investigate a fine aggregate source. Trenches were excavated to depths ranging from 12 to 15 feet (3.7 to 4.6 m). Representative bulk samples averaged 400 pounds (182 kg) per trench. The sample from the fine aggregate trench weighed approximately 800 pounds (364 kg). Two bulk samples of surface rock, weighing about 1200 pounds (545 kg) each, and one additional sample of fine aggregate, weighing about 1200 pounds (545 kg), were collected manually.

Field studies also included 46 petrographic and grain-size data field stops and valley-wide photogeologic field reconnaissance. These analyses were performed to supplement and confirm the office studies and to provide a broader data base for lithologic and gradation correlations of basin-fill units.

4.1.2.3 Laboratory Testing

The laboratory aggregate testing program was performed in two phases. The first phase consisted of standard tests for determining the basic properties of the aggregates and included the following:

- o Unit Weights and Voids in Aggregates;
- o Standard Specifications for Concrete Aggregates;
- o Soundness of Aggregates, Magnesium Sulfate (MgSO_4) and Sodium Sulfate (NaSO_4);

- o Sieve Analysis by Washing, less than No. 200 fraction;
- o Fineness Modulus;
- o Specific Gravity and Absorption, Coarse and Fine Aggregates;
- o Resistance to Abrasion, Los Angeles Machine;
- o Sieve Analysis, Coarse and Fine Aggregates; and
- o Petrographic Examination of Aggregates for Concrete.

Generally, these tests were performed on aggregates from different locations within the same sources previously tested and identified as the most promising in the VSARS program. This repetitive testing was done to confirm the suitability of aggregates for concrete (see Section 4.1.1, Requirements for Concrete Aggregates). Table 1 lists the number of tests completed in Pine Valley.

The second phase of the testing consisted of an evaluation of the concrete-making properties of the aggregates when used in the following three trial (check) concrete mixes.

- Mix 1 - 7.5 sacks (94 pounds per sack) of cement per cubic yard of concrete with 1.5-inches maximum aggregate size.
- Mix 2 - 8.5 sacks (94 pounds per sack) of cement per cubic yard of concrete with 1.5-inches maximum aggregate size.
- Mix 3 - 8.5 sacks (94 pounds per sack) of cement per cubic yard of concrete with 0.75-inch maximum aggregate size and a superplasticizer.

In all three trial mixes, fly ash, as a pozzolan, replaced 20 percent of the cement by weight. All concrete trial mix design criteria are presented in Table 2. Samples were collected for a

CONCRETE TRIAL MIX DESIGN CRITERIA
PINE VALLEY, UTAH

12 JUN 81

TABLE 2

total of four trial mixes; two basin fill (coarse and fine aggregates) and two rock (coarse aggregates) and basin fill (fine aggregates). Material greater than 1.5 inches was crushed to conform to gradation requirements. If necessary, coarse and fine aggregates were processed to conform to gradation requirements.

The following tests were performed to evaluate fresh and hardened properties of concrete made from Pine Valley aggregates:

Fresh Properties

- o Unit Weight, Yield and Air Content of Concrete;
- o Slump of Portland Cement Concrete;
- o Air Content of Concrete, Volumetric Method;
- o Making and Curing Concrete Specimens;
- o Making and Testing Accelerated Cure Concrete Compression Test Specimens; and
- o Selecting Proportions for Normal and Heavyweight Concrete.

Hardened Properties

- o Compressive Strength of Cylindrical Concrete Specimens;
- o Length Change of Hardened Cement Mortar and Concrete;
- o Potential Alkali-Silica Reactivity, Mortar-Bar Method;
- o Static Modulus of Elasticity of Concrete in Compression;
- o Splitting Tensile Strength of Cylindrical Concrete Specimens;
- o Potential Alkali-Carbonate Rock Reactivity, Length Change Method; and
- o Coefficient of Linear Thermal Expansion of Concrete.

The results of all tests summarized in Table 1 are important to the concrete aggregates evaluation, but hardened concrete

properties are considered the most significant (see Section 4.1.1, Requirements for Concrete Aggregates). Although the primary requirement for concrete is a 28-day compressive strength of 6500 psi, one-day (accelerated), seven-day, and 90-day tests were done to determine the range of compressive strength values. In order to compare different aggregate sources, 28-day compressive strengths of Mix 3 were always used.

Occasionally, fresh concrete properties varied from design concrete specifications and may have affected hardened concrete test results. If known or significant, the causative factor and its effect on test results are mentioned in the discussions on sources of concrete aggregates (Sections 4.2.1 and 4.2.2).

The scope of the study did not allow sample collection and laboratory testing of all potential basin-fill and rock concrete aggregate sources. Existing data and field petrographic and grain-size analyses were used to correlate lithologic and gradation properties to basin-fill units which were not sampled. An important element of this correlation procedure was the use of aerial photographs to help delineate the lateral extent of basin-fill deposits. Photogeologic field observations ascertained geomorphological and topographical relationships of basin-fill units and the source rock lithology and distribution of predominantly gravelly materials.

Limited laboratory and field data prevented most correlations of data from tested to untested rock units. Potential aggregate sources were confined to the limits of tested or correlated

outcrops as determined from existing data, limited photogeological interpretation, and field reconnaissance.

4.1.3 Presentation of Results

Results of the concrete aggregates evaluation are presented in the form of text, tables, figures, 1:62,500 scale drawings, and appendices. Drawing 1 is a location map showing the position in the study area of all data points used in the Detailed Aggregate Resources Study. All data points are grouped by study type and assigned categorized map numbers (see Section 3.1.3).

Drawing 3 presents the locations of the potential concrete aggregate sources, basin-fill sources of fine aggregate that were mixed with crushed rock, DARS trenches, DARS field petrographic and grain-size data stops, and select VSARS data stops in the study area. Geologic unit symbols used in Drawing 3 relate to standard geologic nomenclature whenever possible. A conversion table relating these symbols to the geologic unit nomenclature used in other Ertec reports is contained in appendix Table F-3.

A solid contact line separates basin-fill and rock units in Drawing 3 to differentiate these two basic material types. All rock contacts are taken from published data or limited air-photo interpretation and are dashed. Basin-fill contacts are derived from photogeological mapping with limited field reconnaissance and are also dashed.

Classifications of potential basin-fill and rock concrete aggregate sources are distinguished by different patterns.

Patterns for basin-fill and rock sources of the same classification are similar, with the basin-fill pattern emphasized by a dark background tone.

The appendices contain tables that summarize the basic field data collected during the course of the study and the subsequent laboratory test procedures and results. Appendices A and B contain DARS trench data and petrographic and grain-size data, respectively. Appendix C contains representative trench logs. appendix Table D-2 presents a laboratory testing flow diagram for the concrete aggregates evaluation. Appendix E presents the chemical analyses of cement, fly ash, and water used in making all concrete trial mixes. Appendix F includes three tables describing soil classification, caliche development, and geologic unit cross reference.

4.1.4 Classification of Concrete Aggregates

A classification system was designed to present the most likely basin-fill and crushed-rock concrete aggregate sources. It was developed from an evaluation as well as from an extrapolation of all available data. Data include laboratory test results (compressive strength of concrete and grain-size, abrasion, and soundness of aggregates) and geomorphological and compositional correlations.

The classification system groups potential aggregate sources into three categories:

1. Aggregate sources which were used in concrete mixes - Class CA1 and Class CA2;

2. Aggregate sources which were subjected to basic aggregate tests - Class CB; and
3. Untested aggregate sources which were correlated to Classes CA1, CA2, or CB - Class CC1 and Class CC2.

The classification is presented in hierarchy form; classification of the highest potential source areas is described first, and classification of the lowest potential source areas is described last.

<u>Class</u>	<u>Explanation</u>
CA1	Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths equal to or greater than 6500 psi using Mix 3 (Section 4.1.2).
CA2	Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths less than 6500 psi using Mix 3 (Section 4.1.2).

The Classes CA1 and CA2 describe those specific sources where basin-fill or crushed-rock aggregates have been collected and used in making trial mix batches of concrete. Following appropriate ASTM standards, concrete cylinders containing the collected aggregates were made, cured, and tested for various hardened concrete properties. The class is divided into two categories by 28-day compressive strength test results.

Generally, aggregates from each potential source area have been tested previously during the VSARS program. Confirmation testing that included gradation, abrasion, and soundness tests

was performed when applicable to ensure the continued acceptability of a sample for use in concrete. Abrasion and MgSO_4 soundness values do not exceed coarse aggregate requirements specified in Section 4.1.1. Tested samples of fine aggregate used in the concrete trial mixes occasionally have MgSO_4 soundness losses exceeding the required 15 percent maximum, however, NaSO_4 soundness losses do not exceed 10 percent.

<u>Class</u>	<u>Explanation</u>
CB	Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on acceptable laboratory aggregate test results.

The Class CB describes those source areas that have been sampled and tested only for grain-size gradation, abrasion, and MgSO_4 soundness. Trial concrete mixes were not made. Gradation, abrasion, and soundness values specified in Section 4.1.1 were used to assign this classification to an aggregate source.

<u>Class</u>	<u>Explanation</u>
CC1	Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on correlation with Class CA1 or CA2 areas.
CC2	Basin-fill sources of aggregates potentially suitable for use in concrete; based on correlation with Class CB areas.

Untested Class CC deposits are correlated to tested Class CA or CB deposits on the basis of field observations and limited field and laboratory test results. Class CC basin-fill deposits consist of units of the same apparent relative age as Class CA

and CB deposits. Class CC1 rock deposits are additional nearby outcrops of the same unit as Class CA deposits.

Field observations and petrographic and grain-size analyses provided correlative data on lithology of adjacent source rock and lithology and general amounts of gravel present in the basin-fill units. Photogeologic interpretations were also used to correlate Class CC basin-fill deposits to Class CA or CB basin-fill deposits. Specific geomorphological parameters correlated during the procedure included surface texture, drainage patterns, relative relief, and topographic profiles.

All classifications are based on limited data. Additional field reconnaissance, testing, and case history studies are needed to confirm adequacy, delimit exact areal boundaries, and refine chemical and physical properties.

4.2 SOURCES OF CONCRETE AGGREGATES

4.2.1 Basin-Fill Sources

Basin-fill sources of concrete aggregates are grouped into five classes. Deposits defined on the basis of laboratory test data are included in Classes CA1, CA2, and CB. Untested basin-fill deposits correlated to deposits with test data are in Classes CC1 and CC2.

4.2.1.1 Class CA1

There is one Class CA1 basin-fill concrete materials source identified within the study area. This deposit is located on the east side of the valley south of Highway 21 adjacent to the Wah Wah Mountains.

1. The Class CA1 basin-fill source is an alluvial fan deposit (Aaf) located adjacent to the Wah Wah Mountains between latitudes 38°15' N and 38°30' N (Drawing 3). This deposit consists mainly of poorly to well-graded sandy gravel. The gravel ranges from 53 to 63 percent of the deposit (excluding cobbles and boulders) and the sand ranges from 28 to 39 percent. Cobbles and boulders comprise about four percent of the total material within the deposit. Silt and clay comprise seven to 10 percent of the deposit.

The gravel clasts sampled from the Class CA1 deposit are typically subangular in shape. Approximately 71 percent of the gravel clasts are of satisfactory physical quality; 29 percent are porous, weak, and internally fractured and are of fair physical quality; no gravel is considered to be poor in quality. The collected gravel sample is composed of approximately 13 percent dolomite, 82 percent limestone and dolomitic limestone, four percent quartzite and quartzose sandstone, and one percent chalcedonic chert. About 63 percent of the gravel clasts are partially coated by calcareous material. The dolomite and dolomitic limestone clasts are potentially susceptible to a deleterious degree to the alkali-carbonate rock reaction. The chalcedonic chert present in the sample is potentially susceptible to a deleterious degree to the alkali-silica reaction.

The sand particles from the sampled CA1 deposit are typically subangular in shape and are generally similar in composition and quality to the gravel clasts within the deposits. Approximately 63 percent of the sampled sand particles are satisfactory in physical quality; 27 percent are porous, weak, or internally fractured and are fair in physical quality; and about 10 percent are soft, highly porous particles and are of poor quality. The

collected sand sample is composed of approximately 77 percent dolomite and limestone, five percent quartz and quartzose sandstone, and 18 percent feldspar, other sandstone, and coating material. Dolomitic limestones and calcitic dolomites are potentially susceptible to a deleterious degree to the alkali-carbonate rock reaction. Rhyolites and chalcedonic chert are potentially susceptible to the alkali-silica reaction.

Although the percentages of coarse aggregates passing the 1-inch to No. 4 sieves within the Class CA1 deposit conform to the design gradation requirements (Figure 5), the percentage of gravels passing the 1- to 2-inch sieves is below the design requirements. The percentages of fine aggregates do not conform to design gradation requirements except for the sand passing the No. 16 and No. 30 sieves. There is a deficiency of coarse sand passing the No. 4 to No. 16 sieves and an excess of fine sand passing the No. 50 to No. 200 sieves. Processing will be necessary to bring the deposit within gradation requirements. Oversize clasts are present and can be crushed to produce additional aggregates of all sizes. Variations in grain-size gradations will occur within the deposit depending on proximity to the source area. In general, this deposit is relatively finer grained near the valley axis and coarser grained adjacent to the mountain fronts.

A coarse aggregate sample from this Class CA1 deposit was subjected to laboratory abrasion and $MgSO_4$ soundness tests and yielded losses of 25.9 and 3.5 percent, respectively. These

REQUIRED GRAIN-SIZE DISTRIBUTION ENVELOPES FOR COARSE AND FINE AGGREGATES USED IN CONCRETE (AMERICAN SOCIETY FOR TESTING AND MATERIALS, 1978, C 33; THE RECOMMENDED GRADATIONS FOR AGGREGATES WITH 1.5 AND 0.75 INCH MAXIMUM SIZE ARE COMBINED INTO ONE ENVELOPE).

values for abrasion and soundness are well within acceptable values for coarse concrete-construction material use. The fine aggregate sample from this Class CA1 deposit was subjected to both MgSO_4 and NaSO_4 soundness tests. The sample failed the MgSO_4 soundness test with a 19.2 percent loss but passed the NaSO_4 soundness test with a 4.5 percent loss.

Concrete (Mix 3) made using the aggregates from the Class CA1 deposit had a 28-day compressive strength of 7140 psi and a 90-day compressive strength of 8030 psi. Concrete trial Mixes 1 and 2 yielded 28-day compressive strengths of 4830 psi and 5055 psi, respectively (Table 3). Fresh concrete properties and hardened concrete test results (chord modulus of elasticity, splitting tensile strength, drying shrinkage) are also included in Table 3. All test results for hardened concrete are within or exceed the requirements mentioned in Section 4.1.1 except for the tensile strength value of Mix 3.

The areal extent of the Class CA1 deposit is approximately 1.8 mi^2 (4.7 km^2). It is estimated that the material sampled from this deposit and described above extends to a depth of at least 25 feet (7.6 m). It is also estimated that this deposit has a yield of 60 to 70 percent after gradation deficiencies, handling, poor-quality constituents, and silt and clay losses.

4.2.1.2 Class CA2

There is one Class CA2 basin-fill concrete materials source identified within the study area. This deposit is located on

TABLE 3

the east side of the valley north of Highway 21 adjacent to the Wah Wah Mountains.

1. The Class CA2 basin-fill source is an alluvial fan deposit (Aaf) located adjacent to the Wah Wah Mountains between latitudes 38°30' N and 38°45' N (Drawing 3). This deposit consists mainly of poorly to well-graded sandy gravel. The gravel ranges from 60 to 72 percent of the deposit (excluding cobbles and boulders) and the sand ranges from 25 to 35 percent. Cobbles and boulders comprise about five to 14 percent of the total material within the deposit. Silt and clay comprise three to six percent of the deposit.

The gravel clasts sampled from the Class CA2 deposit are typically subangular to subrounded in shape. Approximately 76 percent of the gravel clasts are of satisfactory physical quality; 22 percent are porous, weak, and internally fractured and are of fair physical quality; and about two percent are soft and highly porous and are of poor quality. The collected gravel sample is composed of approximately 48 percent dolomite, 50 percent limestone and dolomitic limestone, and two percent chalcedonic chert, calcareous coating material, and weathered andesite tuff. About 60 percent of the gravel clasts are partially or completely coated by firm to soft calcareous material. The dolomite and dolomitic limestone clasts are potentially susceptible to a deleterious degree to the alkali-carbonate rock reaction. Minor chalcedonic chert and volcanic tuff material are potentially susceptible to a deleterious degree to the alkali-silica reaction.

The sand particles from the sampled Class CA2 deposit are typically subangular to subrounded in shape and are generally similar in composition and quality to the gravel clasts within

the deposit. Approximately 69 percent of the sand particles sampled are satisfactory in physical quality; 23 percent are porous, weak, or internally fractured and are of fair physical quality; and about eight percent are soft, highly porous particles and are of poor quality. The sampled sand is composed of approximately 76 percent dolomite and limestone, 10 percent rhyolite and chalcedonic chert, six percent quartz, and eight percent feldspar, weathered sandstone, and coating material. All the sand is considered to be potentially susceptible to a deleterious degree to the alkali-carbonate rock reaction. Minor chert and volcanic tuff are potentially susceptible to a deleterious degree to the alkali-silica reaction.

Within the Class CA2 deposit, the percentages of coarse aggregates passing the 1-inch to No. 4 sieves conform to the design gradation requirements (Figure 6). However, the percentages of gravels passing the 2- to 1-inch sieves are deficient. The percentages of fine aggregates do not conform to design gradation requirements except for the sand passing the No. 16 to No. 30 sieves. There is a deficiency of coarse sand passing the No. 4 to No. 16 sieves and an excess of fine sand passing the No. 30 to No. 200 sieves. Processing will be necessary to bring the deposit within gradation requirements. Oversize clasts are present and can be crushed to provide additional aggregates of all sizes. Variations in grain-size gradations will occur within the deposit depending on proximity to the source area. In general, this deposit is relatively finer grained near the valley axis and coarser grained adjacent to the mountain fronts.

FIGURE 8

A coarse aggregate sample from this Class CA2 deposit was subjected to laboratory abrasion and MgSO_4 soundness tests and yielded losses of 26.1 and 1.6 percent, respectively. These values for abrasion and soundness are well within acceptable values for coarse concrete-construction material use. The fine aggregate sample from this Class CA2 deposit was subjected to the MgSO_4 soundness test and passed with an 11.4 percent loss.

Concrete (Mix 3) made using the aggregates from the Class CA2 deposit had a 28-day compressive strength of 6240 psi and a 90-day compressive strength of 8440. Concrete trial Mixes 1 and 2 yielded 28-day compressive strengths of 5535 psi and 5880 psi, respectively (Table 4). Fresh concrete properties and hardened concrete test results (chord modulus of elasticity, splitting tensile strength, drying shrinkage) are also included in Table 4. Generally, test results for hardened concrete are within the requirements mentioned in Section 4.1.1.

The areal extent of the Class CA2 deposit is approximately 4.2 mi² (10.9 km²). It is estimated that the material sampled from this deposit and described above extends to a depth of at least 25 feet (7.6 m). It is also estimated that this deposit has a yield of 65 to 70 percent after gradation deficiencies, handling, poor-quality constituents, and silt and clay losses.

4.2.1.3 Class CB

Class CB basin-fill aggregate sources are alluvial and stream-channel deposits that have been sampled and laboratory tested

CONCRETE TRIAL MIX TEST RESULTS
PI-A- (32 36)
PINE VALLEY, UTAH

12 JUN 81

TABLE 4

and, on the basis of test results, are considered to be potential sources of concrete aggregates. Class CB deposits have not been used in concrete trial mixes. Test results show that these deposits contain at least 30 percent gravel clasts of all sizes (3-inch to No. 4 sieve sizes), have less than 50 percent abrasion wear, and where applicable, have less than 18 percent loss when subjected to a MgSO_4 soundness test.

There are 10 alluvial fan and one stream-channel Class CB sources in the Pine Valley study area. Most of the alluvial fans are located on the east side of the valley adjacent to the Wah Wah Mountains. The one stream-channel deposit is located in the southern portion of the study area.

Class CB basin-fill deposits generally consist of poorly to well-graded, subangular to subrounded gravelly sand and sandy gravel. The gravel content of most Class CB deposits ranges from about 42 to 72 percent, sand ranges from 21 to 53 percent, and the silt content ranges from four to 18 percent. Depending on location within the valley, most deposits are composed of either carbonate and quartzite clasts or volcanic clasts. There are no significant differences between the alluvial fan deposits and the stream-channel deposit.

Generally, coarse aggregates conform to Class CB design gradation requirements (Figure 7). The percentages of gravels passing the 2- to 1-inch sieves are deficient. Oversize material is available and can be crushed to provide additional aggregates of all sizes. The percentages of sand passing the No. 4 to No. 30

REQUIRED GRAIN-SIZE DISTRIBUTION ENVELOPES FOR COARSE AND FINE AGGREGATES USED IN CONCRETE (AMERICAN SOCIETY FOR TESTING AND MATERIALS, 1978, C 33; THE RECOMMENDED GRADATIONS FOR AGGREGATES WITH 1.5 AND 0.75 INCH MAXIMUM SIZE ARE COMBINED INTO ONE ENVELOPE).

CONCRETE AGGREGATE, CLASS CB
PINE VALLEY, UTAH

12 JUN 81

FIGURE 7

sieves generally meet design gradation requirements. The percentages of fine sand passing the No. 50 to No. 200 sieves are generally excessive. Variations in grain-size gradations will occur within the deposit depending on proximity to the source area. In general, the deposits are relatively finer grained near the valley axis and coarser grained near the mountain fronts.

Laboratory abrasion tests performed on samples from all Class CB deposits resulted in fairly low percent wear values ranging from 21.7 to 32.3 percent. MgSO_4 soundness tests performed on the coarse aggregates from five of the Class CB samples resulted in values ranging from 1.9 to 4.3 percent loss. MgSO_4 soundness test results on fine aggregate samples ranged from 10.4 to 15.7 percent loss.

The areal extent of individual Class CB deposits ranges from 0.6 to 22.0 mi^2 (1.6 to 57.0 km^2). Except for the stream-channel deposit, it is estimated that the material sampled from these deposits extends to a depth of at least 25 feet (7.6 m) and will have a yield of 60 to 70 percent.

4.2.1.4 Class CC1

The Class CC1 sources within the study area are located on the east side of the valley adjacent to the Wah Wah Mountains north and south of Highway 21. They consist of two alluvial fan deposits that have been correlated to the Class CA1 and CA2 deposits on the basis of geomorphological and compositional similarities.

The Class CC1 deposits are therefore considered to be potential source of concrete aggregate consisting of poorly graded, subangular to angular sandy gravel of generally satisfactory physical quality. The lithology of the deposits is predominantly quartzite, limestone, and dolomite with trace amounts of other rock types. The areal extent of the Class CC1 deposits are 0.5 and 1.6 mi² (1.3 and 4.1 km²).

4.2.1.5 Class CC2

Class CC2 basin-fill aggregate sources are alluvial fan deposits that have been correlated to Class CB concrete aggregate sources on the basis of geomorphological and compositional similarities. These deposits are therefore assumed to contain material similar in size and composition to Class CB deposits. Class CC2 deposits are located along the east side of the valley adjacent to the Wah Wah Mountains, along the east boundary of the Desert Range Experimental Station, and south of Highway 21 adjacent to The Needles Range. Individual deposits have areal extents ranging from 0.2 to 7.7 mi² (0.5 to 19.9 km²).

4.2.2 Rock Sources

Rock concrete aggregate sources are grouped into three classes. Rock defined on the basis of laboratory test data are included in Classes CA1 and CB. Class CC1 contains rocks correlated to tested rock units.

4.2.2.1 Class CA1

Two Class CA1 crushed-rock coarse aggregate sources were delineated within the study area. These rock sources are located on

the east side of the study area in the Wah Wah Mountains. The Class CA1 rock source north of Highway 21 is an undifferentiated carbonate rock unit (Cau); the source south of Highway 21 is a quartzite rock unit (Qtz). Both were sampled during this study. The fine aggregates used in conjunction with the Class CA1 rocks are from two basin-fill units. One deposit is located along the east boundary of the Desert Range Experimental Station about 4.5 miles (7.2 km) northwest of the northern rock sample location and the other was manually sampled in a Class CB unit 0.25 mile (0.4 km) southwest of the southern rock stop.

The northern Class CA1 rock sample used in the concrete trial mix consisted of dark- to medium-gray, hard, fine-grained to microcrystalline, massive dolomite. When crushed, this rock produced fragments that were generally angular and ranged from approximately equidimensional to thick-tabular.

Approximately 12 percent of the crushed-rock fragments are internally fractured and are classified as only fair in physical quality. About 87 percent of the crushed-rock fragments are of satisfactory physical quality. Calcareous caliche occurring as individual particles makes up the majority of material classified as poor in physical quality and constitute only one percent of the crushed rock sample. Weathering is present on the surface of the sample with partial coatings of weak, porous calcareous caliche. The rock is not similar to dolomites that are susceptible to a deleterious degree to the alkali-carbonate reaction and may need further investigation to determine the

deleterious degree of reaction. No substances known to be susceptible to a deleterious degree to the alkali-silica reaction are present in the sample.

The sand sample used in conjunction with the Class CA1 rock source is from an older lacustrine deposit (Aol) and consists of poorly graded, well-rounded to angular gravelly sand. Approximately 81 percent of the sand particles are of satisfactory physical quality; 18 percent are moderately weathered, weak, porous, or internally fractured and are of fair quality; and one percent consists of soft, highly porous, poor-quality particles confined to the finest size fractions. The sand is composed of 43 percent dolomite and limestone, 30 percent volcanic rock fragments, 22 percent quartz, and five percent chalcedonic chert, feldspar, heavy minerals, and biotite mica. Many particles are partially coated by firm to soft encrustations of calcareous material that commonly include fine sand. Dolomite and dolomitic limestone are a major constituent in all of the sand-size fractions and may be susceptible to a deleterious degree to the alkali-carbonate reaction. The volcanic particles and chalcedonic cherts are susceptible to a deleterious degree to the alkali-silica reaction.

The crushed-rock aggregates from the Class CA1 deposit were subjected to a laboratory abrasion test which yielded a result of 20.1 percent wear. A MgSO_4 soundness test performed on the crushed rock yielded a result of 0.19 percent loss. These results are well within the maximum allowable values for abrasion

wear and soundness loss for coarse aggregate concrete construction materials. The fine aggregate used in conjunction with the crushed rock passed the $MgSO_4$ soundness test with a 12.9 percent loss.

A 28-day compressive strength of 7470 psi was obtained from concrete trial Mix 3 using Class CA1 crushed rock (Table 5). This same mix had a 90-day compressive strength of 8870 psi. Concrete Mixes 1 and 2, using Class CA1 crushed rock, produced 28-day compressive strengths of 5605 psi and 6125 psi, respectively. Fresh concrete properties and hardened concrete test results (chord modulus of elasticity, splitting tensile strength, drying shrinkage) are also included in Table 5. Test results for hardened concrete are generally within the required limits stated in Section 4.1.1.

The southern Class CA1 rock sample used in a concrete trial mix consisted of a gray-white to pale-pink, hard to moderately hard, massive quartzose sandstone. When crushed, this rock produced fragments that were generally angular with edges and corners slightly rounded as a result of attrition incidental to processing and handling. The particle shape ranges from approximately cubic to thick-tabular or platy.

About 60 percent of the crushed-rock fragments are of satisfactory physical quality. Approximately 40 percent of the crushed-rock fragments are internally fractured, porous, or platy and are of fair physical quality. No fraction of the crushed rock is considered to be poor in physical quality. Only

TABLE 8

2

trace amounts of other constituents other than quartz are present as sand grains or intergranular material. No constituents known or thought to be susceptible to deleterious cement-aggregate reactions were found in the sample.

The sand sample used in conjunction with the Class CA1 rock source is from an alluvial fan deposit (Aaf) which consists of poorly graded, well-rounded to angular sandy gravel. Approximately 66 percent of the sand particles are of satisfactory physical quality and 29 percent are soft or highly porous and are fair in physical quality. Only five percent of the sand particles are poor in physical quality. Most of the poor-quality materials are granules of calcareous coating material. The sand is comprised of 79 percent dolomite and limestone, five percent quartz, nine percent sandstones, six percent feldspars, heavy minerals, biotite mica, coating material, and a trace of rhyolite. Most of the particles are heavily coated by firm to soft, finely porous, and absorptive calcareous material, commonly intermingled with fine sand. Particles of rhyolites that are potentially susceptible to a deleterious degree to the alkali-silica reaction constitute negligible proportions of the sand. Dolomites and limestones are potentially susceptible to a deleterious degree to the alkali-carbonate reaction.

The crushed-rock aggregates from the Class CA1 deposit were subjected to a laboratory abrasion test which yielded a result of 30.4 percent wear. A MgSO_4 soundness test performed on the crushed rock yielded a result of 0.91 percent loss. These results are well within the maximum allowable values for abrasion

wear and soundness loss for coarse aggregate concrete construction materials. The fine aggregate used in conjunction with the crushed rock passed the $MgSO_4$ soundness test with a 12.5 percent loss.

A 28-day compressive strength of 8205 psi was obtained from concrete trial Mix 3 using Class CA1 crushed rock (Table 6). This same mix had a 90-day compressive strength of 9685 psi. Concrete Mixes 1 and 2, using Class CA1 crushed rock, produced 28-day compressive strengths of 6045 psi and 6610 psi, respectively. Fresh concrete properties and hardened concrete test results (chord modulus of elasticity, splitting tensile strength, drying shrinkage) are also included in Table 6. Test results for hardened concrete are generally within the required limits stated in Section 4.1.1.

4.2.2.2 Class CB

Class CB crushed-rock sources are rock units that have been sampled and laboratory tested and on the basis of the test results, are considered to be potential concrete aggregate sources. Class CB rocks have not been used in concrete trial mixes.

Two Class CB limestone (Ls) rock sources within the study area are located in the Wah Wah Mountains north of Highway 21 between latitude $38^{\circ}30'$ N and $38^{\circ}45'$ N. One additional source of Class CB rock is a quartzite (Qtz) unit located in The Needles Range just south of latitude $38^{\circ}30'$ N. The two limestone unit samples in the Wah Wah Mountains are light to dark-gray, fine to medium-grained, thinly bedded to massive limestone. The quartzite unit

CONCRETE TRIAL MIX TEST RESULTS
PI-R-3 AND PI-FA-3
PINE VALLEY, UTAH

12 JUN 81

TABLE 6

2

in The Needles Range is a light-brown to white, thin- to thick-bedded, fine- to medium-grained orthoquartzite with interbedded sandstone and shale near the base and top of the unit.

Laboratory abrasion tests performed on the Class CB crushed rocks yielded results ranging from 30.5 to 37.1 percent wear. When subjected to a MgSO_4 soundness test, the crushed rocks exhibited a range of values from 1.6 to 9.2 percent loss. All results are well below the maximum allowable abrasion wear of 50 percent and soundness loss of 18 percent for coarse aggregate used as concrete construction material.

4.2.2.3 Class CC1

Class CC1 potential concrete aggregate sources are untested rock outcrops of the undifferentiated carbonate rock (Cau) and quartzite (Qtz) units. Published geologic maps were used to delineate these extensive and widespread outcrops. These sources are part of the same geologic unit as the Class CA1 sources and have essentially the same lithologies; limestone, dolomitic limestone, and quartzite.

5.0 CONCLUSIONS

Results of the Detailed Aggregate Resources Study indicate that there are sufficient quantities of aggregates available for the construction of the MX missile system in the Pine Valley study area.

Good- to high-quality basin-fill and crushed-rock coarse aggregates are present along the east side of the valley. Sufficient quantities of fair-quality, fine aggregates are present in basin-fill deposits in the valley. After shelter layouts are finalized, potential borrow areas can be delineated based on the results of this study.

Although most rock will supply acceptable coarse aggregates, limited sources are delineated in this study. Sufficient quantities of basin-fill aggregates within the valley will probably make processing of crushed-rock aggregates unnecessary.

As discussed in the report, field studies placed an arbitrary cut-off limit of a minimum of 30 percent gravel for the source to be considered for road-base or concrete aggregates. Nevertheless, basin-fill deposits with less than 30 percent gravel are also probably potentially suitable for use as aggregates. However, yield from such sources will be low and extensive processing and/or blending will be required to satisfy the gradation requirements.

5.1 ROAD-BASE AGGREGATES

5.1.1 Class RB1a Sources

Twelve basin-fill deposits consisting of good- to high-quality coarse aggregates acceptable for road base have been located within the study area. All of the deposits are alluvial fan units (Aaf) confined to the east side of the valley. Their total areal extent is approximately 70 mi² (181 km²).

Gradation results indicate that, where sampled, the deposits approximate ASTM standards and DARS requirements. Sand and fine gravel sizes are within design gradation requirements. Percentages of gravels passing the 1.5- to 0.75-inch sieves are generally deficient. Crushing and blending can be used to bring individual deposits within design gradation requirements. In addition, grain-size variations will occur depending on sample location within the deposit. Generally, finer grained material can be obtained nearer the valley axis and coarser grained material can be obtained near mountain front source areas.

Abrasion and soundness results on tested samples are generally within ASTM standards and DARS requirements.

Five good- to high-quality coarse aggregate crushed-rock sources which are acceptable for use as road-base aggregates have been delineated within the study area. These sources are fairly extensive outcrops of quartzite (Qtz), limestone (Ls), and undifferentiated carbonate rocks (Cau). Samples from these rock sources yielded test results for abrasion and soundness

well within acceptable ranges as specified by ASTM standards and DARS requirements.

5.1.2 Class RB1b Sources

Eleven basin-fill deposits within the study area are defined as potential sources of good- to high-quality coarse aggregates suitable for use as road-base construction material. Geomorphological and compositional similarities were used to correlate these units to tested RB1a deposits. The units are all alluvial fan units (Aaf) confined to the east side of the valley. Their total areal extent is approximately 40 mi² (104 km²).

5.1.3 Class RB1I Sources

Several potential road-base aggregate sources defined by limited field and laboratory data are present throughout the study area. All deposits are alluvial fans, consist predominantly of sandy gravel or gravelly sand, and are compositionally similar to Class RB1a and RB1b deposits. These deposits have a total areal extent of approximately 66 mi² (171 km²).

5.2 CONCRETE AGGREGATES

5.2.1 Class CA1 Sources

One basin-fill deposit consisting of good- to high-quality aggregates that produced concrete with 28-day compressive strengths equal to or greater than 6500 psi has been delineated within the study area. Chord modulus of elasticity, splitting tensile strength, and drying shrinkage results generally conform to the standard concrete requirements.

Gradation results indicate that, where sampled, the deposits approximate ASTM standards and DARS requirements. The percentages of coarse gravels passing the 1- to 2-inch sieves are deficient. Generally, the percentages of medium and fine gravels (1-inch to No. 4) conform to gradation specifications. The fine aggregate samples generally contain a deficiency of sand passing the No. 16 sieve and an excess of fine sand passing the No. 50 to No. 200 sieves. Processing of the basin-fill deposits can be used to bring gradations within design requirements. Crushing of oversize material will produce additional aggregates of all sizes. In addition, variations in grain-size gradation will occur within the deposit depending on proximity to the source area. Aggregates are relatively finer grained near the valley axis and coarser grained near the mountain fronts.

Abrasion and soundness tests performed on coarse aggregates from the Class CA1 deposit are within specified ASTM and DARS requirements. The fine aggregates within the deposit are generally of lower quality (high MgSO_4 soundness losses) but results are inconclusive regarding their use as concrete construction material. The Class CA1 basin-fill deposit is an alluvial fan unit (Aaf) located on the east side of the valley. Its total areal extent is approximately 2 mi^2 (5.2 km^2).

Two Class CA1 crushed-rock sources (Cau and Qtz) were delineated on the east side of the study area. The crushed-rock coarse aggregates from these sources have acceptable abrasion and soundness test results, and the local sand (fine aggregates) used in the mixes had acceptable MgSO_4 soundness losses.

5.2.2 Class CA2 Sources

One basin-fill source delineated on the east side of the study area produced concrete with a 28-day compressive strength of less than 6500 psi. Abrasion and soundness tests performed on the coarse aggregates and soundness on the fine aggregates from this deposit yielded test results within acceptable ranges as specified by ASTM standards and DARS parameters.

5.2.3 Class CB Sources

Eleven basin-fill deposits consisting of good- to high-quality coarse aggregates potentially acceptable for use as concrete construction material were delineated within the study area. These deposits are all alluvial fan units (Aaf) and are confined to the east side of the valley. Their total areal extent is approximately 65 mi² (168 km²). No concrete trial mixes were made, but gradation, abrasion, and soundness test results on all basin-fill and rock samples are within acceptable ranges as specified by ASTM standards and DARS requirements.

5.2.4 Class CC1 Sources

Two basin-fill alluvial fan units in the study area are classified as potential sources of concrete aggregates. The units were correlated to Class CA1 sources based on geomorphological and compositional similarities. These deposits have a total areal extent of approximately 2 mi² (5.2 km²).

5.2.5 Class CC2 Sources

Several alluvial units located along the east side of the valley are classified as potential sources of concrete aggregates.

Units were correlated to Class CB sources on the basis of geomorphological and compositional similarities. They have a total areal extent of approximately 18 mi² (46.6 km²).

6.0 RECOMMENDATIONS FOR FUTURE STUDIES

The conclusions of this Detailed Aggregate Resources Study of Pine Valley, as enumerated in Section 5.0, are based on limited field and laboratory test results. However, the results presented in this report provide sufficient data for selecting potential borrow areas. After selection of the borrow areas, more extensive studies are required to further determine the characteristics of the aggregates.

6.1 SOURCES OF ROAD-BASE AGGREGATES

It is recommended that additional field exploration (backhoe or drilling) and detailed laboratory testing be performed. The laboratory tests should consist of sieve analysis, resistance to abrasion, CBR, and other appropriate tests as deemed necessary by the designers.

6.2 SOURCES OF CONCRETE AGGREGATES

It is recommended that additional field investigations (backhoe or drilling) and detailed laboratory testing be performed. The aggregate samples should be subjected to the following tests:

- o Sieve Analysis;
- o Resistance to Abrasion;
- o Soundness;
- o Specific Gravity and Absorption; and
- o Petrographic Examination of Aggregates for Concrete.

In addition, the following detailed tests using concrete made from these aggregates should be performed:

- o Compressive Strength;
- o Splitting Tensile Strength;
- o Flexural Strength;
- o Shrinkage;

- o Thermal Expansion;
- o Modulus of Elasticity;
- o Potential Alkali-Silica Reactivity;
- o Potential Alkali-Carbonate Rock Reactivity; and
- o Resistance of Concrete to Rapid Freezing and Thawing.

In addition, it is recommended that concrete trial mixes with different size aggregates and admixtures be made in order to assess the variation in compressive strength, durability, shrinkage, and thermal properties of concrete.

Verification studies (FN-TR-27-PI-I and II) performed in Pine Valley indicate that potential for sulfate attack of soils on concrete ranges from "negligible" to "mild." However, it is recommended that additional studies be made to further evaluate the potential for sulfate attack of soils on concrete and to determine the type of cement to be used in concrete.

APPENDIX A
SUMMARY OF FIELD AND LABORATORY TEST DATA

FIELD AND LABORATORY TEST DATA

Field observations and laboratory test data on samples collected at selected stations are presented in Table A-1. Field stations were established at various locations throughout the study area where detailed descriptions of potential basin-fill, fine aggregate, and crushed-rock sources were recorded. Detailed explanations for the column headings of Table A-1 are as follows:

<u>COLUMN HEADING</u>	<u>EXPLANATION</u>
MAP NUMBER	Map numbers are sequentially arranged identifiers of field stations occupied during the course of the aggregate study.
FIELD STATION	These designations are internal DARS identifiers of all field stations. Each one consists of a two-letter valley abbreviation followed by the letter A (aggregate trench), FA (fine aggregate trench), or R (ledge rock).
LOCATION	The location column lists the geographic portion of the valley in which the field station is located (e.g., NE-northeast).
GEOLOGIC UNIT	The geologic unit listed is a term used to differentiate basin-fill deposits based on geomorphology and rock units based on existing geologic maps. A geologic unit cross reference, outlining all units used, is included as Table F-3.
MATERIAL DESCRIPTION	Material descriptions are based on either field or laboratory USCS classifications using appropriate ASTM standards for basin-fill deposits and existing references and Travis (1955) for rock units. Coarse and fine aggregate gradations used in concrete trial mix designs are included at the end of each concrete aggregate trench group.
USCS SYMBOL	Appropriate field or laboratory ASTM standards are used to classify sampled

material. The Unified Soil Classification System is used in this study. Table F-1 contains detailed information on the USCS.

FIELD OBSERVATIONS

Boulders and/or Cobbles

The estimated occurrence of boulders and cobbles is based on an appraisal of the entire deposit. Cobbles have an intermediate diameter of 3 to 12 inches (8 to 30 cm); boulders have an intermediate diameter of 12 inches (30 cm) or more. Because of sample-size limitations, boulders were not generally sampled. Cobbles were representatively sampled for concrete aggregate evaluations but only generally sampled for road-base aggregate evaluations. Field observations of boulders and cobbles are important considerations for in-situ gradations only. Number percentages are equated to the following equivalent dry weight terms:

Rare - 1 - 4 percent
Few - 5 - 20 percent
Some - > 20 percent

Gravel

Coarse aggregate particles that pass a 3-inch (76-mm) sieve but are predominantly retained on a No. 4 (4.75 mm) sieve.

Sand

Fine aggregate particles that almost entirely pass a No. 4 sieve but are predominantly retained on a No. 200 (0.075 mm) sieve.

Fines

Soil particles that pass a No. 200 sieve (silt and clay).

Overburden Thickness (Feet)

Surficial soil overlying a usable aggregate deposit. Material generally consists of silt and sand with low concentrations of gravel. Numbers presented indicate thickness of deposit in feet.

Total Trench Depth (Feet)

Depth, in feet, of trench excavation used to collect aggregate samples. Depth followed by the letter R indicates that depth below which soil strength exceeded excavation capability. The common conditions for refusal (R) are calcium carbonate accumulation (caliche) and/or presence of oversized material.

Deleterious
Materials
(Material/Depth/
Stage)

Deleterious materials are substances that are potentially detrimental to concrete in service. Substances that may be present include: organic impurities, low density materials (ash, vesicles, pumice, cinders), amorphous silica (opal, chert, chalcedony), volcanic glass, caliche and clay coatings, mica, gypsum, pyrite, chlorite, friable materials, and aggregates that may react chemically or be affected chemically by other external influences. The most common deleterious material is calcium carbonate accumulation (caliche). When it is abundant, the interval(s) at which it occurs and the stage of development (Table F-2) are listed. Caliche can occur disseminated throughout a deposit, as lenses, and as discrete layers. The depth space is left blank when caliche is present throughout the deposit.

Plasticity
(Index)

Plasticity index (PI) is the range of water content, expressed as a percentage of the weight of the oven-dried soil (less than No. 40 sieve material), through which a soil behaves plastically. It is defined as the liquid limit minus the plastic limit. Field terms used to approximate plasticity index range include the following.

Plasticity PI

Wet Consistency

Slight (4-15)

Slightly sticky; after pressure, soil adheres to both thumb and finger but comes off cleanly. Does not appreciably stretch.

Medium (15-30)

Sticky; after pressure, soil adheres to both thumb and finger and tends to stretch somewhat before pulling apart from either digit.

High (>30)

Very sticky; after pressure, soil adheres strongly to both digits and is markedly stretched when digits are separated.

Hardness

Hardness determination is a field test used to identify materials that are soft or poorly bonded by estimating their resistance to crushing by impact with a

	rock hammer. Classification terms used include:
Soft	Hammer point indents deeply with firm blow.
Moderately Hard	Hammer point indents only shallowly with firm blow.
Hard	Hammer breaks hand-held sample with one firm blow.
Very Hard	Hammer breaks intact sample with many blows.
<u>Weathering</u>	Weathering is defined as any changes in color, texture, strength, chemical composition, or other properties of rock due to the effects of various atmospheric conditions. Field terms used to classify degree of weathering include: fresh, slight(ly), moderate(ly), or very weathered.

LABORATORY TEST DATA

Sieve Analysis
(ASTM C 136)

A sieve analysis is the determination of the proportions of particles existing within certain size ranges in granular material by separation on sieves of different size openings, expressed as a weight percent of the total sample. Numbers presented represent the percent of the sample passing through the stated sieve size. Sieve sizes include: 3-inch (75-mm), 2 1/2-inch (63-mm), 2-inch (50-mm), 1 1/2-inch (38.1-mm), 1-inch (25-mm), 3/4-inch (19-mm), 1/2-inch (12.5-mm), 3/8-inch (9.5-mm), No. 4 (4.75 mm), No. 8 (2.36 mm) No. 16 (1.18 mm) No. 30 (0.6 mm), No. 50 (0.3 mm), No. 100 (0.15 mm), No. 200 (0.075 mm).

Specific Gravity
and Absorption
(ASTM C 127 and 128)

In general, specific gravity is defined as the ratio of the weight in air of a unit volume of material to the weight in air of an equal volume of water. Absorption is the process by which a liquid is drawn into and tends to fill permeable pores in a porous solid body, also, the increase in weight of a porous

solid body resulting from the penetration of a liquid into its permeable pores. Specific definitions of bulk, bulk saturate-surface-dry (SSD), and apparent specific gravity, as well as absorption are contained in ASTM-E 12-70 and C 125, respectively.

Fineness Modulus

Fineness modulus is an empirical factor obtained by adding the total percentages of a sample of aggregate, retained on each of a specified series of sieves, and dividing the sum by 100.

Unit Weight

Unit weight is the weight of a unit volume of dry, rodded aggregate, commonly expressed as pounds per cubic foot (pcf).

Abrasion Test
(ASTM C 131)

The abrasion test is a method for testing resistance to wearing away by rubbing and friction, by placing a specified quantity of aggregates in a steel drum (the Los Angeles testing machine), rotating the drum 500 times, and determining the percent of material worn away.

Soundness Test
(ASTM C 88)

Soundness tests are used to determine resistance to large or permanent volume changes of aggregates by placing samples in saturated solutions of magnesium or sodium sulfate. The test furnishes information useful in studying resistance to weathering action, particularly when adequate service records of the material tested are not available. For concrete aggregate tests, magnesium sulfate soundness tests are run first. If the material fails this test, sodium sulfate soundness tests are performed.

Petrographic
Examination
(ASTM C 295)

A petrographic examination is a procedure used to identify the physical and chemical properties of aggregates that have a bearing on the quality of the material in consideration of its intended use. Typical properties analyzed include: description and classification of constituents, relative amounts of constituents, particle coatings, rock type, particle condition

and particle shape, texture and structure, color, mineral composition and heterogeneities, and presence of constituents known to cause deleterious chemical reactions in concrete.

Alkali Reactivity

Alkali-Silica ASTM C 227

A potential alkali-silica reactivity test evaluates the susceptibility of cement-aggregate combinations to expansive reactions involving the alkalis sodium and potassium by measurement of the increase (or decrease) in length of mortar bars containing the combination during storage under prescribed conditions of test.

Alkali-Carbonate ASTM Proposed Standard

A potential alkali-carbonate reactivity test evaluates the susceptibility of cement-aggregate combinations to expansive reactions involving the carbonates of dolomite (in certain calcitic dolomites and dolomitic limestones) by measurement of the increase (or decrease) in length of concrete specimens (prisms) containing the combination during storage under prescribed conditions of test. This test is a proposed ASTM standard and has not been formally approved by the American Society of Testing and Materials.

AGGREGATE USE CLASSIFICATION

Road Base Aggregate

- | | |
|-------|--|
| RB Ia | Basin-fill or rock sources containing materials suitable for use as road-base aggregates; based on acceptable laboratory aggregate test results. |
| RB Ib | Basin-fill sources containing materials suitable for use as road-base aggregates; based on correlation with Class RB Ia areas. |
| RB II | Potential basin-fill sources of materials suitable for use as road-base aggregates; based on photogeologic interpretations, field observations, and limited or inconclusive sieve analysis and/or abrasion data. |

Concrete
Aggregate

- CA1 Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths equal to or greater than 6500 psi.
- CA2 Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths less than 6500 psi.
- CB Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on acceptable laboratory aggregate test results.
- CC1 Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on correlation with Class CA1 or CA2 source areas.
- CC2 Basin-fill sources containing aggregates potentially suitable for use in concrete; based on correlation with Class CB source areas.
- FA Basin-fill sources containing fine aggregates used with crushed-rock samples for certain concrete trial mixes.

SUMMARY OF FIELD PETROGRAPHIC
AND GRAIN-SIZE ANALYSES

FIELD PETROGRAPHIC AND GRAIN-SIZE ANALYSES

Field petrographic observations are presented in Table B-1. Field stations were established at various locations throughout the study area where detailed petrographic descriptions of potential basin-fill sources of aggregates were recorded. Detailed explanations for the column headings of Table B-1 are as follows:

<u>COLUMN HEADING</u>	<u>EXPLANATION</u>
MAP NUMBER	Map numbers are sequentially arranged identifiers of field petrographic stations occupied during the course of the aggregate study.
FIELD STATION	These designations are internal DARS identifiers of field petrographic designations.
LOCATION	The location column lists the geographic portion of the valley in which the field station is located (e.g., NE-northeast).
GEOLOGIC UNIT	The geologic unit listed is a term used to differentiate basin-fill deposits based on geomorphology. A geologic unit cross reference, outlining all units used, is included as Table F-3.
FIELD OBSERVATIONS	
<u>Clast Count</u>	Clast or petrographic counts are the main data collected during the field petrographic analysis. Data collected include lithology and percent present by size. Categorization by lithology is done to determine general percentages of nondeleterious and deleterious materials.
<u>Other Deleterious Clasts Present</u>	This column is reserved for recording additional types of materials present that are of poor quality for use as aggregate. Items mentioned include samples of rock types not sieved, counted, and described under clast count, such as: amorphous silica

(chert, opal, chalcedony), volcanic glass, mica, chlorite, friable materials, low density clasts (ash, vesicles, pumice, cinders), gypsum, pyrite, organic material, and coatings (clay and caliche).

Size Distribution

The estimated occurrence of boulders and cobbles is based on the appraisal of an entire deposit only if the materials are observed in the banks of prominent stream channels. Size distribution information for gravel was generally recorded only at trench locations. Any gravel values given are expressed as a percent of the total amount of less than 3.0-inch material present. The numeral zero is used to indicate a size fraction not observed, and the letter R is used to indicate the rare occurrence of a size fraction (one to four percent).

Gradation

Gradation information was recorded at trench locations only.

Maximum Particle Size

Maximum particle size is defined as the intermediate diameter length of the most frequently occurring clast present in a deposit (in centimeters). Erratic oversized materials (boulders, large cobbles) are generally not represented as the maximum particle size.

Particle Shape

Shape of clasts are classified into the following six categories.

- | | |
|------------------|---|
| Angular (ANG) | Particles have sharp edges and relatively plane sides with unpolished surfaces. |
| Sub-angular (SA) | Particles are similar to angular but have somewhat rounded edges. |
| Sub-rounded (SR) | Particles exhibit nearly plane sides but have well-rounded corners and edges. |
| Rounded (R) | Particles have smoothly curved sides and no edges. |
| Platey (P) | Particles are thin and flat with either rounded or nonrounded corners and edges. |
| Elongate (E) | Particles are several times longer than they are wide with rounded corners and edges. |

Remarks

This column is used to describe the general site location of petrographic field stations; location terms used include: surface, shallow wash, stream channel bank or bottom, borrow pit, and road cut. Surface indicates analysis was performed on top of the stated geologic unit. Shallow wash indicates analysis was performed on top of the unit but at the bottom of a small swale. Stream channel bank or bottom indicates analysis was performed in an exposed section (incision) or within a minor stream channel deposit, respectively.

PAGE 4 OF 4

APPENDIX C
TRENCH LOGS

EXPLANATION OF TRENCH LOGS

Trench logs were completed for excavated trenches. Each log presented in this appendix is chosen from a group of trench logs so that it represents the general aggregate conditions and properties of that entire group. Occasionally, the full compliment of trenches in a group was not excavated due to low gravel percentages and/or advanced caliche development found in the first one or two trenches of that group. Detailed explanations of the trench logs headings are as follows:

COLUMN HEADINGEXPLANATION

BULK SAMPLE

Representative samples were obtained by channel sampling a trench wall. Overburden and, in some trenches, dense caliche layers were avoided during the sampling procedure.

II - 100 lb. sample (2 bags) for road-base aggregate testing.

III - 400 lb. sample (55 gallon barrel) for concrete aggregate testing.

DEPTH

Depth corresponds to depth below ground surface in meters and feet.

LITHOLOGY

Graphic representation of soil types present in excavation.

USCS

Unified Soil Classification System symbols. For detailed information see Table F-1.

CONSISTENCY

The consistency of the in-situ deposit was estimated by visual observation of the soil in the trench walls, ease (or difficulty) of excavation of the trench, and trench-wall stability.

Consistency descriptions of coarse-grained soils (GW, GP, GM, GC, SW, SP, SM, SC) are as follows:

DESCRIPTIONVery Loose (VL)

Will not hold vertical cut (when dry).

<u>Loose (L)</u>	Will hold vertical cut, but caves if disturbed.
<u>Medium Dense (MD)</u>	Holds vertical cut, even when disturbed; easily excavated.
<u>Dense (D)</u>	Holds vertical cut, difficult to excavate.
<u>Very Dense (VD)</u>	Very difficult to impossible to excavate.

SOIL DESCRIPTION

Except in cases where samples were classified based on laboratory data, the descriptions are based on visual classification. The procedures outlined in ASTM D 2487-69, Classification of Soils for Engineering Purposes and D 2488-69, Description of Soils (Visual-Manual Procedure) were followed. Solid lines across the column indicate known changes in the strata at the depth shown.

Definitions of some of the terms and criteria used to describe soils and conditions encountered during the excavation follow:

Descriptive Name Name of soil, as determined by USCS, preceded by an adjective indicating the size range of the most abundant secondary material present.

Particle Size For coarse-grained soils (sands and gravels) the size range of the particles visible to the unaided eye was estimated as fine, medium, coarse, or a combined range (e.g., fine to medium). These terms approximately correspond to the following sieve sizes:

Gravel	Fine	No. 4 to 3/4-inch sieve
	Coarse	3/4-inch to 3-inch sieve
Sand	Fine	No. 200 to No. 40 sieve
	Medium	No. 40 to No. 10 sieve
	Coarse	No. 10 to No. 4 sieve

Particle Shape See Appendix B explanation pages.

Gradation Gradations listed are those determined from percent amounts of boulders, cobbles, and gravel present. Descriptive terms used include: poor and well.

<u>Poor(ly)</u>	Predominantly one size or a range of sizes, with some intermediate sizes missing.
<u>Well</u>	Wide range in grain sizes present, with substantial amounts of most intermediate sizes.
<u>Secondary Material</u>	Percentage present by dry weight. Trace 5-12 percent Little 13-20 percent Some > 20 percent (e.g., <u>Some slightly plastic silt</u>)
<u>Plasticity of Fines</u>	See Appendix A explanation pages
<u>HCL Reaction</u>	As an aid for identifying calcium carbonate coatings and cementation, soil samples were tested in the field for their reaction to dilute hydrochloric acid. The intensity of the HCL reaction was described as none, weak, or strong.
<u>Caliche</u>	Caliche is a term applied to calcareous material of secondary accumulation. In this study, the definition includes both the soluble calcium (and other) salts and the clastic material (gravel, sand, silt or clay) in which the salts exist. See Table F-2 for a description of the stages of caliche development.
<u>Cobbles and Boulders</u>	See Appendix A explanation pages.
<u>Lithology</u>	The various rock types found in an excavated deposit are listed in order of decreasing abundance.
<u>Remarks</u>	This column was provided for comments regarding difficulty of excavation, caliche development, and backhoe refusal. Refusal indicates the inability of a JCB 3DIII backhoe (Case 680 equivalent) with a 2-foot wide bucket to excavate a trench to completion.
SIEVE ANALYSIS	The numbers cited represent the percentage by dry weight of each of the following soil components.

- GR Coarse aggregate particles that pass a 3-inch (75 mm) sieve but are predominantly retained on a No. 4 (4.75 mm) sieve.
- SA Fine aggregate particles that almost entirely pass a No. 4 sieve but are predominantly retained on a No. 200 (0.075 mm) sieve.
- FI Soil particles that pass a No. 200 sieve (silt and clay).

All percentages shown on logs are the result of laboratory testing.

APPENDIX F
UNIFIED SOIL CLASSIFICATION SYSTEM
SUMMARY OF CALICHE DEVELOPMENT
ERTEC WESTERN GEOLOGIC UNIT CROSS REFERENCE

E-TR-47-PI

Figure 1. Unified Soil Classification System

This figure presents the Unified Soil Classification System, a standardized method for categorizing soils based on their plasticity and grain size. It includes a detailed table of classification criteria, a plasticity chart, and a liquid limit chart.

Group Symbol	Typical Names	Information Required for Describing Soils	Laboratory Classification Criteria
GV	Well graded, gravelly, sand mixtures, little or no fines	Give typical name; indicate approximate percentages of sand and gravel; maximum size; angularity, surface condition, and texture; local or regional name; and other pertinent descriptive information; and symbols in parentheses	$C_u = \frac{D_{60}}{D_{10}}$ Greater than 4 $C_c = \frac{D_{30}^3}{D_{10} \times D_{60}}$ Between 1 and 3
GP	Poorly graded gravels, gravelly sand mixtures, little or no fines	Same as GV	Same as GV
GM	Silty gravel, poorly graded gravel-sand-clay mixtures	Same as GV	Same as GV
GC	Clayey gravel, poorly graded gravel-sand-clay mixtures	Same as GV	Same as GV
SW	Well graded sands, gravelly sand mixtures, little or no fines	Same as GV	Same as GV
SP	Poorly graded sands, gravelly sand mixtures, little or no fines	Same as GV	Same as GV
SM	Silty sands, poorly graded sand-silt mixtures	Same as GV	Same as GV
SC	Clayey sands, poorly graded sand-silt mixtures	Same as GV	Same as GV
ML	Inorganic silts and very fine sand, rock flour, silty or clayey fine sands with slight plasticity	Give typical name; indicate degree of plasticity; maximum size; angularity, surface condition, and texture; local or regional name; and other pertinent descriptive information; and symbols in parentheses	Same as GV
CL	Inorganic clays of low to medium plasticity, silty clayey, sandy clay, silty clay	Same as GV	Same as GV
OL	Organic silts and organic silty clays of low plasticity	Same as GV	Same as GV
MH	Inorganic silts, medium to high plasticity, silty, clayey silts	Same as GV	Same as GV
CH	Inorganic clays of high plasticity, silty, clayey	Same as GV	Same as GV
OM	Organic clays of medium to high plasticity	Same as GV	Same as GV
PT	Peat and other highly organic soils	Same as GV	Same as GV

Plasticity Chart

The Plasticity Chart is a graph showing the relationship between the Plasticity Index (PI) on the y-axis and the Liquid Limit (LL) on the x-axis. The chart is divided into regions for different soil types: CL (Clay of low plasticity), CH (Clay of high plasticity), ML (Silt of low plasticity), MH (Silt of medium plasticity), and OL (Organic silt). The chart also includes a line for the A-line and a line for the U-line.

Liquid Limit Chart

The Liquid Limit Chart is a graph showing the relationship between the Liquid Limit (LL) on the y-axis and the Plasticity Index (PI) on the x-axis. The chart is divided into regions for different soil types: CL (Clay of low plasticity), CH (Clay of high plasticity), ML (Silt of low plasticity), MH (Silt of medium plasticity), and OL (Organic silt). The chart also includes a line for the A-line and a line for the U-line.

DIAGNOSTIC CARBONATE MORPHOLOGY

STAGE	GRAVELLY SOILS	NONGRAVELLY SOILS
I	Thin, discontinuous pebble coatings	Few filaments or faint coatings
II	Continuous pebble coatings, some interpebble fillings	Few to abundant nodules, flakes, filaments
III	Many interpebble fillings	Many nodules and internodular fillings
IV	Laminar horizon overlying plugged horizon	Laminar horizon overlying plugged horizon

Stages of development of a caliche profile with time. Stage I represents incipient carbonate accumulation, followed by continuous build-up of carbonate until, in Stage IV, the soil is completely plugged.

References: Gile, L.G., Peterson, F.F., and Grossman, R.B., 1966, The K horizon: A master horizon of carbonate accumulation: *Soil Science*, v. 90, p. 74-82.

FIGURE F-2

U ARSA POTENTIAL AGGREGATE SOURCE SYMBOLS

ERTEC WESTERN GENERAL GEOLOGIC UNIT EXPLANATION

0000

Some regions where rock is exposed, the locally predominant (greater than 70 percent) rock type is indicated. In those areas where two rock types occur the predominant rock type is shown followed by the subordinate rock type (e.g., S₁ L₂). Rock may be subdivided into bedrock (B).

GR	I	IGNEOUS (UNDIFFERENTIATED): Rocks formed by solidification of a molten or partially molten mass
Vu	I ₁	Extrusive: Plutonic rocks formed by solidification of molten material beneath the surface (e.g., granite, granodiorite, diorite, gabbro)
Vb	I ₂	Extrusive (intermediate and acidic): Volcanic rocks of intermediate and acidic composition formed by solidification of molten material at or near the surface (e.g., rhyolite, latite, dacite, andesite)
Vu	I ₃	Extrusive (basic): Volcanic rocks of basic composition, generally formed by solidification of molten materials at or near the surface (e.g., basalt)
Su	I ₄	Extrusive (pyroclastic): Rocks formed by accumulation of volcanic ejecta (e.g., ash tuff, welded tuff, agglomerate)
Su, Qtz	S	SEDIMENTARY (UNDIFFERENTIATED): Rocks formed by accumulation of clastic solids, organic solids and/or chemically precipitated minerals
Ls, Do, Cau	S ₁	Sandstones and/or Siliceous Rocks: Composed of sand-size particles (e.g., sandstone, orthoquartzite) or of crystalline silica (e.g., agate, chert)
	S ₂	Carbonate Rocks: Composed predominantly of calcium carbonate detritus or chemical precipitates (e.g., limestone, dolomite, chalk)
	S ₃	Argillaceous Rocks: Composed of clay and silt-sized particles (e.g., siltstone, shale, claystone)
	S ₄	Evaporite Rocks: Precipitated from solution as a result of evaporation (e.g., halite, gypsum, anhydrite, sylvite)
Su	S ₅	Coarse Clastic Rocks: Composed of gravel-sized or larger clasts (e.g., conglomerate, breccia)
Mu	M	METAMORPHIC (UNDIFFERENTIATED): Rocks formed through recrystallization in the solid state of preexisting rocks by heat and pressure
Mu	M ₁	Coarse-grained: Rocks formed by high-grade regional metamorphism, either banded or granular (e.g., gneiss, granulite, amphibolite)
Mu	M ₂	Fine-grained: Schistose rocks formed by lower grade regional metamorphism (e.g., schist, slate, phyllite)
Mu	M ₃	Metacrystalline: Rocks formed chiefly by contact metamorphism (e.g., hornfels, marble)
Qtz	M ₄	Diagenetic: Rocks formed by metamorphism of highly siliceous rocks
		0010-FILL
Aal	A	0010-FILL DEPOSITS: Fine- to coarse-grained materials deposited principally by wind, water or gravity
Au, Aal	A ₁	Younger Fluvial Deposits: Major modern stream channel and flood-plain deposits
Au	A ₂	Older Fluvial Deposits: Older incised stream channel and flood-plain deposits in elevated terraces bordering major modern drainages
Aol	A ₃	Eolian Deposits: Wind-blown deposits of sand occurring as either thin sheets (A _{3a}) or dunes (A _{3b})
Aaf	A ₄	Playa and Lacustrine Deposits: Deposits occurring in modern active playas (A _{4a}) or in either inactive playas or older lake beds and abandoned channels associated with ancient lakes (A _{4b})
Au	A ₅	Alluvial Fan Deposits: Alluvial deposits consisting of debris flow and water-laid alluvium near mountain fronts, grading into predominantly water-laid alluvium deposited in shifting distributary channels near the basin center. Younger (A _{5a}) intermediate (A _{5b}) and older (A _{5c}) alluvial fans are differentiated by surface soil development, terracing conditions and present depositional gradient orientation
Au	A ₆ /A ₇	Shed rock units: Most recently deposited unit is listed first
Aaf	A ₈ (A ₉)	Pyroclastic unit underlies thin veneer of overlying alluvial unit

CROSS REFERENCE FROM MAP
NUMBER TO VERIFICATION ACTIVITY

CROSS REFERENCE FROM MAP NUMBER
TO VERIFICATION ACTIVITY

Included in this appendix is one table that is presented to allow cross reference to be made from this aggregate resources study to an appropriate verification study. Map numbers in the number series 400 to 599 on Drawing 1 are keyed to the published Verification report of Pine Valley, Utah (FN-TR-27-PI-I and II). If detailed information is required from a verification activity, the following search procedure can be used: determine the location of the activity required on Drawing 1, note the map number, refer to that map number in Table G-1, read from that table the verification activity type and number, refer to the appropriate verification report for the data required.

MAP NUMBER	ACTIVITY LOCATION	MAP NUMBER	ACTIVITY LOCATION

EXPLANATION

CLASSIFICATION SYSTEM

SIN-FILL OR ROCK SOURCES CONTAINING AGGREGATES THAT PRODUCED TRIAL MIX CONCRETE WITH 28 - DAY COMPRESSIVE STRENGTHS EQUAL TO OR GREATER THAN 6500 PSI.

SIN-FILL OR ROCK SOURCES CONTAINING AGGREGATES THAT PRODUCED TRIAL MIX CONCRETE WITH 28 - DAY COMPRESSIVE STRENGTHS LESS THAN 6500 PSI.

SIN-FILL OR ROCK SOURCES CONTAINING AGGREGATES POTENTIALLY SUITABLE FOR USE IN CONCRETE; BASED ON ACCEPTABLE LABORATORY AGGREGATE TEST RESULTS.

SIN-FILL OR ROCK SOURCES CONTAINING AGGREGATES POTENTIALLY SUITABLE FOR USE IN CONCRETE; BASED ON CORRELATION WITH CLASS CA1 OR CA2 SOURCE AREAS.

SIN-FILL SOURCES CONTAINING AGGREGATES POTENTIALLY SUITABLE FOR USE IN CONCRETE; BASED ON CORRELATION WITH CLASS CB SOURCE AREAS.

SIN-FILL SOURCES CONTAINING FINE AGGREGATES BASED WITH CRUSHED-ROCK SAMPLES FOR CERTAIN CONCRETE TRIAL MIXES.

POTENTIALLY SUITABLE SOURCES OF BASIN-FILL MATERIALS THAT MAY LOCALLY CONTAIN POTENTIALLY SUITABLE SOURCES OF AGGREGATES OF LIMITED EXTENT. UNTESTED SOURCES OF ROCK MATERIALS THAT MAY CONTAIN POTENTIALLY SUITABLE CRUSHED-ROCK AGGREGATES (SEE TEXT FOR ADDITIONAL INFORMATION).
