20. ABSTRACT (Continue on reverse side if necessary and identify by block number) Results of regional carbonate aquifer testing in Coyote Spring Valley, Nevada wells can be constructed in the aquifer to produce long term, sustained yields. The test well produced 3400 gpm continuously over a 30 day period of time. No impacts were detected in the regional springs of the Middle River Springs area.		

FOREWORD

This report was prepared for the U.S. Department of the Air Force, Ballistic Missile Office, in compliance with Contract No. F04704-80-C-0006. It presents partial results of Ertec Western's investigations of the water-supply potential of the regional carbonate aquifers in the proposed Nevada-Utah MX deployment area.

This report contains all data compiled during the drilling and testing of carbonate exploration well CE-DT-5 in Coyote Spring Valley, Nevada. Plans for additional testing of the carbonate aquifer in Coyote Spring Valley and further evaluation of the data compiled at CE-DT-5 were cancelled due to the President's decision not to implement the proposed MPS basing of the MX missile system in Nevada and Utah. Therefore, all conclusions and interpretations herein are considered preliminary.

A number of state, federal, and private agencies and individuals cooperated in the testing of CE-DT-5. Special acknowledgement is made to the Nevada Division of Water Resources who provided flumes and maintained recorders for one month after the completion of testing, the Nevada Power Company who provided observation well data through the Desert Research Institute, University of Nevada System; the U.S. Geological Survey, who performed water sampling and standard chemical and isotopic analyses; and to the individuals who gave permission for well and spring monitoring on privately owned land in upper Moapa Valley, Nevada.

---	--	----------------------------------

1.0 INTRODUCTION

Coyote Spring Valley was identified as a candidate location for the Main Operating Base (MOB) for the MX missile system in Nevada. In February 1980, Ertec, then Fugro National, initiated a water resources investigation in the valley as part of the U.S. Air Force's MX Water Resources Program. Data obtained from published literature and from Air Force test wells indicated that the valley-fill aquifer was incapable of supplying an adequate amount of water for construction and operation of the facility. Based on these results, studies to evaluate the water-supply potential of the regional carbonate aquifer were initiated. Regional geologic reconnaissance and exploratory drilling and testing of the regional carbonate aquifer in Coyote Spring Valley were begun on 20 November 1980. Results of subsequent drilling and testing conducted in 1981 are discussed in this report.

1.1 PURPOSE AND SCOPE

The purpose of this hydrologic investigation was to 1) evaluate the potential of the regional carbonate aquifer to supply water for the construction and operation of the proposed MOB; and 2) evaluate the impacts of ground-water withdrawals from the regional carbonate aquifer in Coyote Spring Valley on water users in the Muddy River Springs area.

The scope of this investigation involved drilling and testing of a large diameter well (designated CE-DT-5) in the regional

carbonate aquifer in Coyote Spring Valley. One carbonate observation well (CE-DT-6) was also drilled in the valley during the 1981 program. Monitoring of carbonate and alluvial wells in Coyote Spring Valley and alluvial wells and regional springs in the upper Moapa Valley (Muddy River Springs area) during aquifer testing was an integral part of the program.

Results presented in this report are based upon previous investigations and Ertec analysis of data compiled during carbonate aquifer drilling and testing. This report does not constitute a complete appraisal of the regional carbonate aquifer system in Coyote Spring Valley but rather the results of a limited testing program in a selected area of the valley. Additional hydrologic studies would be required to fully characterize and evaluate the potential of the regional carbonate aquifer in Coyote Spring Valley as a long-term, water-supply source.

1.2 LOCATION AND GENERAL SITE CHARACTERISTICS

Figure 1 is a general location map of the Coyote Spring Valley study area. The CE-DT-5 well site is located along Nevada Highway 7 just west of the White River Channel (Pahrnagat Wash) in Township 13 South, Range 63 East, southeast 1/4 of the southeast 1/4 of Section 23, M.D.M. (T13S/R63E-23dd). The study area includes all of Coyote Spring and Kane Springs valleys and the Muddy River Springs area (upper Moapa Valley). For a detailed discussion of the geography, geology, and basic hydrology of the area, the reader is referred to E-TR-51-I,

Water Resources Program, Operational Base Studies Report, Volume I, Coyote Spring Operational Base, Nevada (Ertec, 1981).

1.3 REGIONAL HYDROGEOLOGY

1.3.1 Carbonate Hydrostratigraphy

Prior to drilling and testing in Coyote Spring Valley, a regional survey of rock units of Paleozoic age was conducted throughout the MX deployment area. The purpose of this survey was to define the hydrostratigraphic characteristics of the Paleozoic section. Based upon the results of these studies, the Paleozoic stratigraphic section has been divided into 10 hydrostratigraphic units as shown in Figure 2. The areal extent of correlative units within the study area is shown in Drawing 1. A detailed description of each of these units is provided in Section 3.0 of E-TR-52, Water Resources Program, Technical Summary Report (Ertec, 1981).

Although a continuous Paleozoic section is not exposed within the study area, all the Paleozoic units are exposed as segmented fault blocks resulting from Basin and Range faulting. Due to depth considerations, only the upper and middle Paleozoic aquifer units were considered for initial testing. In the study area, these aquifer units include the Bird Springs Formation of Pennsylvannian age, the Monte Cristo Limestone of Mississippian age, and the Sultan Limestone of Upper Devonian age. In most of the study area, these aquifers form a continuous vertical sequence without the intervening aquitard

units which occur to the north. Only in northernmost Coyote Spring Valley does the Scotty Wash Quartzite and the Chainman Shale (aquitard No. 9) occur as a confining layer between the Mississippian and Pennsylvanian aquifers. The Scotty Wash Quartzite and Chainman Shale and the Pilot Shale (aquitard No. 7) have been reported to crop out on the eastern slopes of the Meadow Valley Mountains (Tschanz and Pampeyan, 1970) but are not believed to be present in the Paleozoic sequence underlying Coyote Spring Valley. According to Longwell and others (1979), neither of these aquitard units is present in Coyote Spring Valley south of T12S.

1.3.2 Regional Flow System

Many of the valleys in central and southern Nevada and west-central Utah are hydraulically connected via carbonate aquifers and form regional ground-water flow systems. The White River regional ground-water flow system, as defined by Eakin (1966), encompasses 13 hydrographic basins in central and southern Nevada and includes both Coyote Spring and Kane Springs valleys and the Muddy River Springs area.

The boundaries of the White River flow system and the inferred regional potentiometric surface are shown in Figure 3. Shown in Table 1 is a list of regional and possible regional springs in the White River flow system. The criteria used to define regional springs were based on water chemistry, temperature, and discharge rate. Possible regional springs are those which meet only two of the criteria standards established for

REGIONAL AND POSSIBLE REGIONAL SPRINGS

30 NOV 81

TABLE 1

regional spring status. A detailed description of the procedures and criteria used to identify these springs is contained in E-TR-52, Water Resources Program, Technical Summary Report (Ertec, 1981).

The boundaries of the flow system are based upon variations in physiography, ground-water-level elevations, geologic structures, and imbalances in valley water budgets. Thick Paleozoic carbonate sequences underlie the valley-fill aquifers and occur in most of the bounding mountain ranges. Where faulted or fractured, secondary dissolution has greatly increased the ability of the carbonates to store and transmit ground water. Ground water which originates as precipitation in the mountainous areas is transmitted through the fracture and fault systems to discharge areas such as springs or evapotranspiration zones. Most of this ground-water flow is presumed to occur along the axis of the system through White River, Pahrnagat, and Coyote Spring valleys (Eakin, 1966).

Recharge from precipitation is significantly less than regional underflow to and discharge from the southern portion of the White River flow system (Coyote Spring and Kane Springs valleys and the Muddy River Springs area). Eakin (1964) estimated that some 35,000 acre-ft/yr ($43.12 \text{ hm}^3/\text{yr}$) of underflow enter Coyote Spring Valley from Pahrnagat Valley and that recharge from precipitation to Coyote Spring and Kane Springs valleys totals only 2600 acre-ft/yr ($3.2 \text{ hm}^3/\text{yr}$). Discharge from the system totals a few hundred acre-ft/yr via evapotranspiration in

Coyote Spring Valley and approximately 36,000 acre-ft/yr (44.4 hm³/yr) of spring discharge at Muddy River Springs, the presumed terminal point of the regional flow system.

The potentiometric surface in the southern part of the flow system slopes southward and then eastward from about 3200 feet (975 m) in elevation at the northern end of Coyote Spring Valley to about 1800 feet (549 m) in the Muddy River Springs area. The elevation of spring discharge in the Muddy River Springs area ranges from 1760 to 1812 feet (536 to 552 m). The occurrence of these springs appears to be related to faulting which forms discontinuities and probably conduits in the carbonate aquifers.

2.0 DRILLING PROGRAM

2.1 SITE SELECTION

Selection of the well site for CE-DT-5 was based on geologic and hydrologic information obtained during drilling and limited testing of an initial carbonate exploration well, CE-DT-4, which was drilled in November 1980. The well site for CE-DT-5 is located 330 feet (100 m) east of CE-DT-4 which provided a nearby observation point for aquifer testing.

Several cultural and hydrogeologic criteria were considered in initial selection of the CE-DT-4- and 5 drill site. These included land ownership and use, avoidance of existing water rights or known wells and springs, site access, carbonate hydrostratigraphy, geologic structure, thickness of alluvial cover, and projected depth to target hydrostratigraphic units. A detailed discussion of these criteria is provided in Appendix A1.1. Reconnaissance geologic mapping and a seismic refraction survey were performed to verify site conditions.

2.2 SITE GEOLOGY

The CE-DT-4- and 5 site is situated in the southeast portion of Coyote Spring Valley within a topographic low known as Starvation Flat. Surficial deposits in the vicinity consist of semi-consolidated clays of the Muddy Creek Formation of Tertiary age and unconsolidated silty sand, sand, and gravel of Quaternary age. Approximately 400 feet (122 m) west of the site, a highly folded and faulted block of cherty, siliceous, fossiliferous limestone crops out. Based on the lithologic character of the

block, it has been identified as Anchor Member of the Monte Cristo Limestone of Lower Mississippian age.

The prominent Arrow Canyon Range lies to the south of the site. This range is an uplifted fault-block of mostly carbonate rocks ranging in age from Ordovician to Mississippian. The range is a broad syncline that plunges north-northwest. The northern tip of the range plunges beneath alluvium approximately 800 feet (284 m) south of the well site. Rocks exposed at the northern tip of the range are of the Anchor Member of the Mississippian Monte Cristo Limestone. This formation has been included in hydrostratigraphic aquifer unit No. 8 as described in the preceding section of this report. Near the alluvial bedrock contact, the Anchor member is cut by numerous faults, most of which trend northwest.

2.3 DRILLING

Drilling of CE-DT-5 commenced on 13 April 1981 using a trailer-mounted Gardner Denver 2500 mud rotary rig. A 26-inch- (66-cm) diameter borehole was drilled through the alluvial cover and 5 feet (1.5 m) into competent carbonate bedrock to a total depth of 126 feet (38 m). Twenty-inch (51-cm) outside diameter surface casing was installed to this depth and pressure-grouted in place.

All subsequent drilling was with 17.5-inch (44.5-cm) diameter bits. Loss of circulation of drilling fluid occurred frequently. A significant zone of lost circulation was encountered at

387 feet (118 m). This zone was found to be dry and was cemented off and drilling proceeded.

The first recognized water occurred between 410 and 450 feet (125 and 137 m). A second zone of significant circulation loss was encountered at 571 feet (174 m). Drilling continued at a slow rate, and circulation could not be regained. Drilling was terminated on 6 May 1981 at a depth of 628 feet (191 m) because the continued circulation loss suggested that significant saturated fracture(s) had been penetrated.

During drilling, lithologic samples were collected at 5-foot (1.5-m) intervals, at apparent formation changes, and whenever changes were observed in drilling conditions. A detailed chronology of drilling activities and a description of the bit and drilling fluid programs are provided in Appendix A1.2. Upon completion of drilling, spontaneous potential, resistivity, natural gamma, 3-D velocity, and 3-diameter caliper geophysical logs were run in the borehole. In addition, video logs were run in both CE-DT-4 and 5. Results of logging are discussed in the following section.

2.4 SUBSURFACE CONDITIONS

Based upon surface correlation and subsurface geophysical information obtained and drill chip cuttings collected, CE-DT-5 penetrated the lowermost 500 feet (152 m) of the Anchor Member of the Monte Cristo Limestone. Although no samples were obtained during the last 57 feet (17 m) of drilling due to loss of circulation, correlation with lithologic unit thicknesses

'n CE-DT-4 suggest that CE-DT-5 was completed 18 feet (5.5 m) into the Dawn Member of the Monte Cristo Limestone. Lithologic, geophysical, and well design logs for CE-DT-4 and 5 are shown in Figures 4 and 5.

Lithologically, the Anchor Member consists of thin to medium-bedded, fossiliferous, cherty and/or siliceous, fine- to medium-grained limestone. The underlying Dawn Member is characterized by a medium-bedded, fine- to medium-grained limestone. The contact between the two members is generally sharp and conformable.

Intercrystalline porosity and permeability of each member is negligible, however, secondary permeability due to faulting and fracturing is generally well developed, especially within the Anchor Member. This increased fracturing is probably due to the more brittle response of the siliceous and cherty portions during deformation. Due to the insoluble nature of the siliceous and cherty portions, the degree of interconnection of small fractures is probably minimal. In contrast, interconnecting fractures within the Dawn Member appears more likely due to the lack of insoluble material.

The extent of fracturing as well as the shape of the fractures were identified by use of a videolog, 6-arm caliper log, and the 3-D velocity log. The videolog was run in both CE-DT-4 and 5, however, due to the lack of well development of CE-DT-5 at the time of logging, the water was too murky to provide

adequate analysis of fracturing below the static water level. Fracture data for CE-DT-5 from analysis of the 3-D velocity log, shown in Figure 6, indicate predominantly oblique fractures due to the attenuation of both the shear (s) and compression (p) waves. Major zones of fracturing of this type occur at 420 to 425 feet (128 to 130 m), 490 to 500 feet (150 to 152 m), 560 to 565 feet (171 to 172 m), 570 to 580 feet (174 to 177 m), and 600 to 610 feet (183 to 186 m). A zone from 510 to 540 feet (155 to 165 m) shows some attenuation of the p wave and a significant attenuation of the s wave. This is believed to indicate a major zone of predominantly horizontal fractures. The 3-D velocity and the 3-diameter caliper log (Figure 7) are generally in close agreement in showing the degree of fracture density. In CE-DT-4, the videolog shows that most of the fractures are near vertical, some of which are approximately 4 to 5 inches (10 to 13 cm) wide.

To assist in the determination of aquifer mechanics, a fracture density analysis was performed for each well videolog. Fractures were counted for each 5-foot (1.5-m) interval and graphs prepared of the number of fractures versus depth (Figures 8 and 9). Less fractured zones occur in fine-grained, cherty limestone units and the highly fractured zones correlated with siliceous and unaltered limestone units. There does not appear to be any decrease in fracture density with depth.

The videolog of CE-DT-4 indicates that the highest fracture density occurs in the presumed water producing zone between 580

and 669 feet (177 and 204 m) below land surface. Although this same trend cannot be observed for CE-DT-5, the correlation between the geophysical logs and fracture density of the two wells also indicates a higher fracture density in the water producing zones in CE-DT-5.

Identification of water-bearing versus nonwater-bearing fractures within CE-DT-5 cannot be readily determined from the various logging tools. An indication of water-bearing zones can, however, be determined by observing the change in viscosity of the drilling mud during actual drilling operations. This information, in conjunction with the 3-D velocity log, indicates that water-bearing zones correlate with the major vertical fractures below the 500-foot (152-m) level. Based on the 3-D velocity log, the main water producing zones presumably occur between 571 to 580 feet (174 to 177 m) and 600 to 610 feet (183 to 186 m). This is supported by the fact that circulation of drilling fluids was lost at 571 feet (174 m) and was never regained. Based on geophysical logs, lithology, and the major zones of lost circulation, the main water-bearing zones presumably occur near the base of the Anchor Member and the top of the Dawn Member (?) of the Monte Cristo Limestone.

3.0 AQUIFER TESTING

3.1 AQUIFER TESTING AND MONITORING PROGRAM

3.1.1 Well Development

Hydrologic testing activities began in mid-June with bailing of the test well and two of the observation wells for the purpose of well cleaning and development. The pump assembly in the test well was set on 29 June and development by pumping began on 3 July continuing intermittently through 9 July. During development, the pump was surged allowing the water in the pump column to backflush the formation.

The pumping equipment used for the aquifer testing at CE-DT-5 is described in Figure 10. The pump was set at a depth of 500 feet (152 m) below land surface. The discharge during pumping was diverted in an easterly direction away from the well through 200 feet (61 m) of 10-inch (25-cm) ID pipe where the water discharged onto a metal spreader box to retard the velocity and then into a modified alluvial channel. The discharge was measured by means of 10 x 7-inch (25 x 18-cm) and 12 x 10-inch (30 x 25-cm) orifice plates and a piezometer tube installed on the discharge pipe.

During initial development on 3 July, the water was gray to black with a fetid odor which began to clear after 30 minutes of pumping at a discharge rate of 600 gpm (38 l/s). The well was subsequently surged at 500 gpm (31 l/s) intervals up to 2700 gpm (170 l/s) in order to clear the water. Development began again on 4 July; the water became murky gray at 2500 gpm

(158 l/s) but cleared in 20 minutes. The well was further developed early on 9 July in five steps up to 3400 gpm (214 l/s) until the water was clear.

3.1.2 Aquifer Testing

Two types of aquifer tests were conducted at CE-DT-5, a step-drawdown test and a series of eight constant discharge tests. The step-drawdown test, consisting of six stages with discharge rates ranging from 600 gpm (38 l/s) to 4000 gpm (252 l/s) was conducted on 9 July. This testing verified that the well could easily sustain the long-term pump/engine capacity of 3400 gpm (214 l/s). This pumping rate was selected for the constant discharge testing.

The constant discharge test was started on 12 July. Pumping shutdowns, due to a variety of mechanical difficulties involving the diesel test engine and pump gearhead assembly, occurred intermittently throughout the first three weeks of testing. Well yield and aquifer characteristic data were obtained during this period. However, because the longest sustained pumping period was approximately four days, results were not deemed appropriate to meet one of the objectives of testing, that being assessment of impacts of long-term continuous water withdrawal. Following a series of repairs to the test engine, pumping was restarted on 31 July. Testing proceeded uninterrupted until 12 August when the Air Force ordered a shutdown at the request of local citizenry who believed the well discharge was contributing to severe flooding which occurred in the Moapa

Valley area on 11 and 12 August. Since this shutdown occurred near the 300-hour mark, scheduled engine maintenance was performed. The test was restarted approximately 24 hours later on 13 August. Test pumping continued uninterrupted until 25 August (294 hours continuous pumping) when a clutch bearing on the test engine failed. A replacement engine was delivered to the site on 26 August and the test restarted. Due to unknown factors, the replacement engine could not achieve design horsepower output and would only pump a maximum of 2700 gpm (170 l/s). Prior to any resolution of this problem, the engine suffered a mechanical breakdown on 27 August. At this point, it was decided to postpone restart of the test until repairs on the original engine were completed. Repairs were completed and test pumping restarted late on 28 August. The test continued without incident through 11 September when a scheduled engine maintenance was performed. After a shutdown period of approximately three hours, the test was continued. The test proceeded with no further mechanical problems or scheduled shutdowns for the duration of the 30-day period. The aquifer test was terminated on 27 September. Total duration of the test period was 30 days and three hours. A detailed chronological history of aquifer testing is provided in Appendix B1.1. A list of tests and test durations is given in Table 2.

3.1.3 Monitoring

An extensive monitoring program was conducted concurrently with aquifer testing at CE-DT-5. The program consisted of monitoring the discharge and water chemistry of six selected

SCHEDULE OF AQUIFER
TESTING AT CE-DT-5

30 NOV 81

TABLE 2

springs and the measurement of water levels in seven observation wells and the test well. All springs and two of the observation wells were in the Muddy River Springs area. Five observation wells were monitored in Coyote Spring Valley. The locations of these monitoring sites are shown in Figure 11. Well and spring descriptions, equipment used for monitoring, frequency of data collection, and tests performed at the monitoring sites are summarized in Table 3.

Four of the observation wells monitored in Coyote Spring Valley were drilled by Ertec Western as part of the MX water resource investigation. The fifth well, the "Old Highway Well", is an abandoned stock well. Water-level data for the pumping well and CE-DT-4 were collected using an electropiezo recorder and pressure transducers with periodic checks made with an electric sounder. One hundred PSI transducers were used in both wells. The barometric pressure was monitored using a 50 psi transducer. All other monitoring wells in Coyote Spring Valley were monitored by electric sounder. Water level measurements for the two wells in the Muddy River Springs area were made available by Nevada Power Company through the Desert Research Institute, University of Nevada System. Water-level data for the pumping well are listed in Appendix B1.2. Water-level data for all observation wells are listed in Appendix B1.3.

Water samples for laboratory analyses were collected from all spring monitoring sites prior to beginning of testing and at

Coyote Spring Valley

- o CE-DT-5 - pumping well
 - 13S/63E-23dd2
 - land surface elevation is 2169.03 feet
 - well depth is 628 feet
 - well has a conductor casing set from 0 to 126 feet and is an open borehole from 126 feet to 628 feet
 - static water level is 349.7 feet below land surface
 - monitored by electropiezo recorder and 100 psi pressure transducer with periodic checks made with an electric sounder
 - water level during pumping and recovery was measured on the schedule defined as follows:

<u>Length of Time from Start of Pumping</u>	<u>Monitoring Interval</u>
0 to 30 minutes	one minute
30 to 60 minutes	five minutes
60 to 240 minutes	30 minutes
240 minutes to end of test	one hour

- o CE-DT-4 - observation well (carbonate)
 - 13S/63E-23dd1 (330 feet west of CE-DT-5)
 - land surface elevation is 2172.58 feet
 - well depth is 669 feet
 - well has a conductor casing set from 0 to 50 feet and is an open borehole completion from 50 feet to 669 feet
 - static water level is 352.3 feet below land surface
 - monitored by electropiezo recorder and pressure transducer (same unit as in pumping well)
 - water level during pumping and recovery measured on the schedule defined as referenced for CE-DT-5
- o CE-DT-6 - observation well (carbonate)
 - 13S/64E-35aa (6.7 miles east of CE-DT-5)
 - land surface elevation is 2274.57 feet
 - well depth is 937 feet
 - well has a conductor casing set from 0 to 87 feet, blank casing from 0 to 325 feet, and is an open borehole from 325 feet to 937 feet
 - static water level is 457.4 feet below land surface
 - monitored by electric sounder
 - water level measured every 12 hours 7/11/81 through 7/30/81 then every 24 hours for the remainder of the test

the completion of the test period. Field measurements of spring discharges and selected chemical parameters were made as summarized in Table 3. Field data collected at the springs are listed in Appendix B1.4. Laboratory analyses results are presented in Appendix B1.5.

During the step-drawdown test, field measurements of pH, temperature, specific electrical conductance, and bicarbonate were made of water from the test well prior to the completion of each step. During constant discharge tests #1 and #2, field measurements were made once every five minutes for the first hour of the test, once every 30 minutes for the next three hours, once every hour for the next eight hours, and once every 12 hours for the remainder of the test. Field measurements were made once every 12 hours during tests #3 through #8. Water samples for laboratory analyses were taken five times during the test period. Laboratory analyses results and field chemistry data for well CE-DT-5 are listed in Appendix B1.5.

3.2 ANALYSIS AND INTERPRETATION

3.2.1 Ground-Water Levels and Spring Discharge Rates

During aquifer testing of CE-DT-5, hydraulic response was observed only at observation well CE-DT-4. No response was observed in other observation wells or at the springs which could be attributed to the pumpage. Diurnal microvariations, which appear as fluctuations in ground-water levels and spring discharge rates, result from cyclic variations in barometric pressure and/or earth tide effects.

Ground-Water Levels

At observation well CE-DT-4, minor water-level declines occurred during the testing of CE-DT-5. The maximum observed drawdown was 0.38 feet (0.12 m) that occurred after 12,000 minutes (8.3 days) of pumping at a constant discharge rate of 3400 gpm (215 l/s) during test #8. The water level drawdown data for CE-DT-4 are shown graphically in Figure 12. No response is readily apparent for the first 500 minutes of testing. Following this, water levels began to exhibit cyclic fluctuations with an overall declining trend for the duration of pumpage. During maintenance shutdowns or pump failures, the water level recovered fully to prepumping levels within three minutes.

The cyclic variations in the water levels at CE-DT-4 correspond in period with variations in barometric pressure. The relationships are inverse, i.e., water-level declines correspond with increases in barometric pressure. As noted by Ferris and others (1962, p. 132), such variations in water levels are indicative of confined aquifer conditions. Shown in Figure 13 are barometric pressure data during a portion of test #6a and #6b. The cyclic pattern is seen to be similar to the fluctuations observed in the drawdown record at CE-DT-4 (Figure 12). Earth-tide effects are also a potential cause of the water-level fluctuations.

FIGURE 13

Spring Discharge Rates

During monitoring of the six springs in the Muddy River Springs area, no changes in discharge rates were observed which could be attributed to the pumpage of CE-DT-5. Shown in Figure 14 is the discharge record for Pederson Spring from 9 August 1981 through 16 August 1980. Fluctuation in spring discharge appears to vary with atmospheric pressure and/or earth tides. Insufficient data are available to define the precise cause of discharge variation.

3.2.2 Well Hydraulics

Well Efficiency

The efficiency of a well is the ratio of theoretical drawdown to observed drawdown (Lennox, 1969). Bierschenk (1964) proposed a method for estimating well efficiency through the analysis of step-drawdown test data. Using this method, well efficiency is defined by the expression:

$$E = \frac{1}{1 + (C/B)Q}$$

where:

E = Well efficiency,

C = Change in specific drawdown with respect to change in discharge rate, i.e.,

$$C = \frac{\frac{s_2}{Q_2} - \frac{s_1}{Q_1}}{Q_2 - Q_1},$$

B = Specific drawdown at a discharge rate of zero, i.e.,

$$B = \frac{s_2 - s_1}{Q_1 s_2 - Q_2 s_1},$$

BMO/AFRC-MX

TIME VS. DISCHARGE RECORD
OF PEDERSON SPRING
9 AUGUST-16 AUGUST 1981

30 NOV 81

FIGURE 14

Q = Discharge in cubic feet per second (cfs),
 Q_1 = Discharge at time = t_1 ,
 Q_2 = Discharge at time = $t_1 + t$,
 s_1 = Drawdown at time = t_1 , and
 s_2 = Drawdown at time = $t_1 + t$.

C and B may be derived either mathematically or graphically from measured values of Q and s during step-drawdown testing.

As discussed by Bierschenk (1964) and Mogg (1968), a number of factors affect the efficiency of a well. These factors include the transmissivity and storativity of the aquifer, boundary conditions, the degree of penetration and development, the discharge rate and length of pumping, aquifer compaction, the occurrence of turbulent flow and friction loss between the formation and the pumping unit, and well construction parameters including the effective open area of the screen or casing at the producing zone and the size and sorting of the gravel pack. For open borehole wells such as CE-DT-5, most of the construction effects do not occur, but the hydrologic effects can be significant.

Shown in Figure 15 is a plot of observed drawdown versus time for the initial step-drawdown test conducted at CE-DT-5. These data include the expected trend of decreasing specific capacity with increasing discharge and time. Results of further pumping, however, indicate that continued development of the well was occurring after the step-drawdown test and, therefore, an accurate determination of well efficiency could not be calculated from these data. Drawdown and discharge data from

30 NOV 81

FIGURE 1B

constant discharge tests #7a and #6 were used for analysis since these tests are, in essence, a long-term, step-drawdown test. These data are graphically shown in Figure 16.

Figure 17 shows the relationship between specific drawdown and discharge for CE-DT-5. The value of B is the Y intercept of the line through the observed data and was calculated to be $0.73 \text{ ft}^{-2}\text{s}$. The value of C is the slope of the line, i.e., the rate of change in specific drawdown with respect to discharge, and was calculated to be 0.09. The value of C agrees well with the correlation between C and discharge observed by Mogg (1968) for 76 step-drawdown tests. This very low value of C is indicative of high discharge rates and high specific capacities.

Figure 18 is a specific capacity diagram for CE-DT-5 based upon observed drawdown and discharge rates and the calculated values for C and B. The observed drawdown at CE-DT-5 has two components, the first is referred to as formation loss and represents the amount of drawdown which would occur at CE-DT-5 if the well were 100 percent efficient, and the second component is referred to as well loss and represents the loss in head and subsequent decrease in well efficiency due to the hydrologic effects discussed previously.

The calculated well efficiency is shown in Figure 18. As expected, the well loss and well efficiency decrease with increasing discharge. The well efficiency at production rates

are low ranging from only 58 percent efficiency at 2658 gpm (168 l/s) to 52 percent at 3414 gpm (215 l/s). These low efficiencies indicate that significant well losses were occurring. It is inferred that most of the calculated well loss can be attributed to friction loss in the borehole between the point where ground water flows from the formation to the point where the water enters the pump intake. The videologs of CE-DT-5 indicate that the surface of the borehole is very irregular and fractured. Assuming a Hazen-Williams coefficient (Chow, 1964) of relative roughness of 50, the calculated friction loss in the 17 1/2-inch (44.4-cm) borehole over 128 feet (39 m) (the distance from the assumed producing zone to the pump intake) is 3.1 feet (0.94 m). This friction loss represents 26 percent of the total drawdown in the well and is believed to be the major source of well loss.

Another possible source of well loss in CE-DT-5 is the effect of turbulent flow in the borehole. Mogg (1968) analyzed the percent reduction in specific capacity as a function of changes in drawdown during step-drawdown tests and suggested that significant turbulent flow losses are incurred in a well if the percent reduction in specific capacity over a given discharge range exceeds 10 percent. As shown in Figure 19, an 11 percent reduction in specific capacity occurred for CE-DT-5 between 2658 and 3414 gpm (168 and 215 l/s) suggesting that turbulent flow in the borehole is also contributing to well loss.

FIGURE 19

Optimum Pumping Rate

In hydrologic terms, the optimum yield of a well is defined as the pumping rate which maximizes discharge while minimizing drawdown. To determine the optimum pumping rate, the well yield (discharge versus drawdown) is plotted along with specific capacity versus drawdown as shown in Figure 20. The optimum pumping rate occurs at the point where the yield curve intersects the specific capacity curve. As shown, the theoretical optimum pumping rate for CE-DT-5 is 2050 gpm (129 l/s) at which drawdown in the well is 5.5 feet (1.6 m) and the specific capacity is 373 gpm/foot (77 l/s/m) of drawdown. The estimated well efficiency at this pumping rate is 64 percent.

The primary application of the optimum pumping rate is in the selection of the most efficient pumping unit. At CE-DT-5, the pump used during testing (a 14EC-8 stage Johnston vertical turbine pump with 11-inch [28-cm] impellers) operates at maximum efficiency at a discharge rate of 2750 gpm (176 l/s) and is too large in capacity for peak operating efficiency at the optimal pumping rate of 2050 gpm (129 l/s). The specific capacity and yield of CE-DT-5 indicate that a smaller capacity pump such as a 14DS-7 stage with 8 1/8-inch (21-cm) impellers could produce the optimum well yield at peak operating efficiency (84 percent) resulting in decreased operating costs.

3.2.3 Aquifer Mechanics

of constant discharge test #8. Drawdown data for test #8 for CE-DT-4 and 5 are listed in Appendix B1.2 and B1.3, respectively.

Transmissivity

Lohman (1972) defined transmissivity (T) as the rate at which ground water is transmitted through a unit width of an aquifer at a unit hydraulic gradient; transmissivity is equal to the product of the hydraulic conductivity (K) and the aquifer thickness (b). A number of techniques have been developed for estimating transmissivity from aquifer test data which take into account the complexity of the hydrologic system and the geometric effects of the well installation.

Shown in Figures 21 and 22 are semilog plots of drawdown versus time for the pumped well, CE-DT-5, and observation well, CE-DT-4, respectively, for test #8. As shown, 90 percent of the total drawdown (11.8 feet [3.4 m]) in CE-DT-5 occurred during the first three minutes of pumping. Analysis of this initial leg of the test will not yield a representative transmissivity for the aquifer because of well bore storage, transient start up conditions, and an initial variable pumping rate. The second leg of the test, between three and 1,000 minutes, exhibits a gentle slope (0.217 feet [0.07 m] of drawdown per log cycle) and indicates the effects of the release of water from compressible storage in the fractures and the commencement of delayed yield of water from the low permeability unfractured limestone blocks into the high permeability

fractures. The third leg of the pump test (beyond 1000 minutes) exhibits a somewhat steeper slope (0.48 feet [0.15 m] of drawdown per log cycle) which probably reflects the combined effects of release of water held in compressible storage in the fractures and in the primary limestone blocks.

The observed data for CE-DT-5 for constant discharge test #8 were analyzed using the Jacob approximation of the Theis equation:

$$T = \frac{264Q}{(s_2 - s_1)} \log \frac{t_2}{t_1}$$

where:

T = Transmissivity,
 Q = Discharge rate of pumping well,
 (s₂-s₁) = Change in drawdown over one log cycle, and
 $\log \frac{t_2}{t_1} = 1$ for one log cycle.

Based upon this method of analysis, the calculated transmissivity of the carbonate aquifer at CE-DT-5 is 1.87 x 10⁶ gallons per day per foot (gpd/ft) (2.32 x 10⁴ m²/day).

The observed data for CE-DT-4 were analyzed using the Jacob method resulting in a calculated transmissivity of 7.48 x 10⁶ gpd/ft (9.29 x 10⁴ m²/day). This estimate is for the second leg of the test curve prior to the commencement of the combined effects of compressible storage in the fractures and the primary blocks. The difference in transmissivity might also be explained by incomplete development of the observation well although it was pumped for in excess of 80 hours during previous testing.

A number of approaches have been developed for the analyses of aquifer test data for fractured flow. Gringarten and Witherspoon (1972) developed type-curve solutions for vertically fractured and horizontally fractured aquifers. These type curves were developed primarily for oil field reservoir analysis from observation well data. The data from CE-DT-4 and 5 did not closely match either the vertical- or horizontal-fracture-flow type curves. The fracture system in CE-DT-4 and 5, as indicated from videologs, includes vertical, horizontal, and inclined fractures; the system is dominated by vertical fractures.

In summary, techniques developed for fracture-flow analysis were not found to be applicable to the observed data from CE-DT-5 testing. The use of standard test analysis techniques for confined aquifers do appear to be applicable. The transmissivity of the carbonate aquifer tapped by CE-DT-4 and 5 is on the order of 1.87×10^6 to 7.8×10^6 gpd/ft (2.32×10^4 to 9.29×10^4 m²/day). It is believed that the value calculated from the pumping well (1.87×10^6 gpd/ft [2.32×10^4 m²/day]) is more representative of long-term aquifer transmissivity. This value is greater than the 900,000 gpd/ft (11,200 m²/day) reported for the carbonate aquifer at the Nevada Test Site by Winograd and Thordarson (1975) and the regional transmissivity of 200,000 gpd/ft (2500 m²/day) estimated by Eakin (1966) for the carbonate aquifers within the White River flow system.

Storativity

The storativity (S) of an aquifer is defined as the specific yield for unconfined aquifers and the storage coefficient for confined aquifers and is the quantity of water which is released from storage per unit decrease in head (Lohman, 1972). Several methods were applied to calculate storativity from drawdown data at CE-DT-4. Standard analyses resulted in indeterminate estimates (for example see Figure 21).

Jacob (in Hantush, 1956) devised a method for estimating storativity which does not require an aquifer test:

$$S = \theta \gamma b (\beta + \alpha / \theta).$$

where:

S = Storativity of the primary limestone block,
 θ = The porosity of the aquifer (assumed to be 0.05),
 γ = The unit weight of water (62 lb/ft³),
 b = The thickness of the aquifer (assumed to be 1000 feet),
 β = The compressibility of water (2.29×10^{-8} ft²/lb), and
 α = The vertical compressibility of the aquifer (assumed to be 6.8×10^{-10} ft²/lb).

Based upon this equation, the storativity of the carbonate aquifer is estimated to be on the order of 1.0×10^{-4} .

Distance-Drawdown Relationships

The extensive monitoring conducted during testing of CE-DT-5 did not show any significant lowering of ground-water levels nor any reduction in spring discharge rates in the Muddy River Springs area. Higher pumpage rates over a longer period of time may, however, cause some minor impacts upon the water levels in the regional aquifer. By using the Theis non-equilibrium equation, and assuming a transmissivity of $1.87 \times$

10^6 gpd/ft (2.32×10^4 m²/day), a storativity of .0001 (confined conditions), a constant discharge rate of 3400 gpm (218 l/s), and a pumping period of 20 years, the drawdown at a distance of 330 feet (100 m) is calculated to be 4.1 feet (1.2 m).

3.2.4 Water Chemistry

Prior to and after completion of aquifer testing, water samples were collected for laboratory analyses from all monitored springs in upper Moapa Valley. During aquifer testing, five water samples for laboratory analyses were collected from CE-DT-5. In addition, field measurements were made of water from pumping well CE-DT-5 and at each spring for temperature, specific conductance, pH, and bicarbonate. All data are listed in Appendix B1.5. Laboratory and field water chemistry analyses showed no significant change in spring or well discharge chemistry over the period of testing.

Ground water at CE-DT-5 is of generally good quality but certain limiting conditions for direct domestic use exist. The water temperature of 95°F (35°C) indicates that cooling or mixing would be required prior to domestic consumption. Fluoride concentrations exceed the Nevada Primary Drinking Water Standard of 1.4 mg/l for areas with annual average maximum daily air temperature in excess of 79.3°F (26.3°C). Fluoride concentrations in the five samples collected from CE-DT-5 ranged from 1.7 to 1.9 mg/l.

A water sample collected on 27 September 1981 had the greatest total dissolved solids (TDS) concentration of 504 mg/l which

slightly exceeds the recommended Nevada Secondary Drinking Standard of 500 mg/l but is well below the maximum permissible level of 1000 mg/l. The range in TDS concentration is shown in Appendix B1.5. In addition, the water samples collected on 31 August and 27 September had arsenic concentrations of 0.01 mg/l which equal the maximum recommended level but are well below the maximum allowable level of 0.05 mg/l.

In cooperation with the Carson City District Office of the U.S. Geological Survey, water chemistry samples for standard and isotope analyses were collected from each of the carbonate exploration wells drilled by Ertec and from selected regional springs. Location of sites not associated with CE-DT-5 testing is shown in Figure 3. Provisional analysis results are given in Table 4. These data indicate that ground-water chemistry in the regional carbonate aquifer at CE-DT-5 is very similar to that of the Muddy River Springs but is dissimilar to regional carbonate water upgradient in the White River flow system.

Previous studies have identified a number of water chemistry trends within the White River flow system (Eakin, 1966). The analysis of the chemical composition of ground water from Ertec carbonate exploration wells and regional springs show a similar trend. As shown in Figure 23, sulfate, potassium, sodium, chloride, and magnesium increase southward through the flow system. Boron, lithium, and strontium also show increasing concentrations. Barium values, however, decrease southward through the flow system.

The provisional records for isotopic analysis for C^{13}/C^{12} , H^2/H^1 , H^3 , O^{18}/O^{16} , C^{14} , and S^{34} were received from the U.S. Geological Survey on 13 November 1981. A rigorous evaluation of this preliminary data has not been conducted. It is believed (U.S. Geology Survey 1981, personal communication) that the ground water at CE-DT-5 is much lighter in tritium (H^3) than sites upgradient in the flow system. These tritium values and other water-chemistry data suggest that the ground water at CE-DT-5 may be older water originating as under flow from the central part of the White River flow system.

Water samples for halocarbon analysis were collected during aquifer testing of previous Ertec carbonate exploration wells and during aquifer testing at CE-DT-5. Sample sites and results are shown in Table 5. These data also indicate that ground water at CE-DT-5 is older than that in the northern part of the flow system. The presence of minor amounts of halocarbons suggest, however, that there may be some mixing of the water with younger recharge water. The samples taken from Warm Spring and Baldwin Spring exhibit very low concentrations of F-11 (trichlorofluoromethane, CCl_3F , or "Freon-11") and trichlorethane and no F-12 (dichlorodifluoromethane, CCl_2F_2 , or "Freon-12") or carbontetrachloride. Well CE-DT-5 also exhibits low F-11 and trichloroethane concentrations, but the presence of F-12 and carbontetrachloride in the water indicates that some mixing with younger recharge water is occurring. The source of some of this water may be the Sheep Range as proposed by Winograd and Friedman (1972).

HALOCARBON ANALYSES FROM CARBONATE AQUIFER INVESTIGATION SITES

30 NOV 81

TABLE 5

4.0 CONCLUSIONS AND RECOMMENDATIONS

Based upon the preliminary results of the hydrologic investigation of well CE-DT-5, it is concluded that:

- o Well CE-DT-5 is capable of a long-term, sustained yield in excess of 3400 gpm (218 l/s);
- o Long-term, constant discharge testing of CE-DT-5 resulted in no detectable impacts upon either the discharge rate or water quality of the regional springs in the Muddy River Springs area;
- o It is likely that some of the water pumped at CE-DT-5 was from deep in the regional carbonate aquifer system;
- o The transmissivity of the regional carbonate aquifer at the CE-DT-4- and 5 site is in excess of 1.0×10^6 gpd/ft (1.24×10^4 m²/day);
- o The regional carbonate aquifer at the CE-DT-4- and 5 site is a confined system with a storativity estimated to be on the order of 1.0×10^{-4} ; and
- o With the exception of fluoride, the ground water in the regional carbonate aquifer at CE-DT-5 is within the maximum allowable water-quality standards for domestic water use in the state of Nevada.

CE-DT-5 was tested at the maximum rate the pumping unit would provide. It is likely that an even greater sustained well yield could be obtained with a larger pumping unit. If CE-DT-5 is to be used as a water-supply well and a larger pumping unit is used, it is recommended that additional testing and monitoring be performed to further quantify potential impacts.

Inspection of the pump bowl assembly after testing indicated extensive impeller damage. This was probably due to inflow of pieces of limestone dislodged from the borehole wall. If CE-DT-5 is to be used as a water-supply well, it is recommended that the existing borehole be cased with well screen installed

opposite the production zone(s). This may result in a decrease in well efficiency and discharge rate and it is therefore further recommended that additional studies be conducted to determine what well design should be used and what size pumping unit will provide the most efficient operation.

Although the preliminary results of the 30-day aquifer test indicated no impacts upon the Muddy River Springs, the long-term impacts of pumpage at CE-DT-5 are not certain. If CE-DT-5 is converted to a production well, it is recommended that a long-term monitoring program be implemented in the Muddy River Springs area.

APPENDIX A1.0

WELL SITING AND DRILLING INFORMATION

A1.0 WELL SITING AND DRILLING INFORMATION

A1.1 SITE-SELECTION CRITERIA

A number of cultural and hydrogeologic parameters were used in the selection of the CE-DT-4- and 5 carbonate test well site in Coyote Spring Valley. Drawing 1 shows the areas of exclusion and geologic and hydrostratigraphic conditions in the valley. This map is based upon the criteria discussed below and the interpretation of data compiled during field reconnaissance investigations.

A1.1.1 Cultural Criteria

A1.1.1.1 Land Ownership and Wilderness Status

Potential sites were limited to areas of public domain under the administration of the Bureau of Land Management which were not presently wilderness areas or under consideration as wilderness areas. This removed over half of the valley floor from siting considerations as well as most of the mountainous areas on the valley flanks.

The following areas were excluded:

- o Desert National Wildlife Range;
- o Delamar Mountains Wilderness Study Area;
- o Meadow Valley Range Wilderness Study Area;
- o Evergreen Wilderness Study Area;
- o U.S. Fish and Wildlife Service No. 1, No. 2, and No. 3 Wilderness Study Areas;
- o All areas within one-half mile of the Pahrnagat National Wildlife Refuge; and
- o Small areas of privately owned land, mostly along Pahrnagat Wash. (White River Channel).

A1.1.1.2 Existing and Pending Water Appropriations

All land within a 1-mile (1.6-km) radius of existing or pending surface or ground-water right points of diversion were excluded from further consideration. The locations of water rights were obtained from inventories conducted by the Desert Research Institute (1980) and Woodburn and others (1981). To avoid infringing upon water rights not identified by these inventories, 1-mile (1.6-km) setback distances were established from all known springs and wells and 0.25-mile (0.4-km) setback distances were established from all major stream channels and existing reservoirs. In addition, a 3-mile (5-km) exclusionary radius was applied to the regional carbonate discharge area in upper Moapa Valley.

A1.1.1.3 Access

Sites were limited to areas with access via existing roads. This criterion was further limited to roads capable of sustaining traffic from the heavy equipment used in well drilling and testing. This effectively excluded all areas more than 0.1 mile (0.2 km) from existing paved or graded roads.

A1.1.2 Hydrogeologic and Geologic Criteria

A1.1.2.1 Aquifers Present

As discussed in Section 1.3, the Paleozoic stratigraphic section in south-central Nevada was divided into 10 discrete hydrostratigraphic units. In the Coyote Spring Valley area, the most suitable units for ground-water development are the Monte Cristo Formation of Mississippian age, which correlates

with the Unit No. 8 aquifer, and Sultan Limestone of Devonian age, which corre lates with the Unit No. 6 aquifer. The Unit No. 7 aquitard (Pilot shale) is not know to be present in the area. Surficial exposures of Units No. 6 and No. 8 aquifers are delineated in Drawing 1 along with other identified aquifer and aquitard units. Potential drilling sites were restricted to areas adjacent to outcroppings of the favorable aquifer units.

A1.1.2.2 Structural Controls

The carbonate rocks in the study area have greatest potential for ground-water development where they have been extensively faulted and fractured. The major identified faults in Coyote Spring Valley are shown in Drawing 1. Geologic reconnaissance indicated intersecting fracture systems at the CE-DT-4- and 5 site.

A1.1.2.3 Projected Drilling Depths

Due to the high cost of drilling large-diameter wells in carbonate rock, the thickness of alluvial cover and the depth of anticipated production zones are important criteria in well site selection. Because these criteria required site-specific field investigation, they were not evaluated until the drilling site had been tentatively selected. To determine the thickness of alluvial cover, two seismic refraction lines were run by Ertec. The location of these survey lines are shown in Drawing 1. Four distinct seismic layers were identified and are listed as follows.

<u>Layer</u>	<u>Seismic Velocity (ft/sec)</u>	<u>Interpreted Lithology</u>
1	1540	Unconsolidated alluvium
2	3800 - 4000	Cemented gravels
3	7600	Consolidated alluvium
4	15,000 - 17,000	Limestone

Figures A1-1 and A1-2 show the seismic refraction profiles. Based upon the survey, the depth to carbonate bedrock at the CE-DT-4- and 5 site was estimated to be from 234 to 526 feet (71 to 160 m). The irregularity of the profiles suggested the presence of numerous faults. Subsequent drilling at the site showed the initial interpretation of depth to bedrock to be significantly in error because bedrock was found in CE-DT-4 and 5 at 50 and 105 feet (15 and 32 m), respectively. This suggests that layer 3 may be altered limestone rather than consolidated alluvium.

The anticipated depth to target hydrostratigraphic aquifer units was assessed based on reconnaissance geologic mapping in the site vicinity. Based on this activity and published geologic information, it was anticipated that the target Monte Cristo Formation (aquifer Unit No. 8) and Sultan Limestone (aquifer Unit No. 6) would be found within 1000 feet (305 m) of land surface.

A1.2 DRILLING HISTORY

A1.2.1 Drilling Program

Summarized below is a chronological description of activities during drilling and logging of CE-DT-5.

<u>Date</u>	<u>Time</u>	<u>Activity</u>
4/7/81	0700	Drilling contractor, equipment, and crew arrived at site and initiated drill-site preparation
4/13/81	2100 2300	Commenced drilling - 26 inch borehole Drilling depth - 10 feet
4/14/81	0321 0645 0945 1045 1145 1515 1700 1745 1815 2045	Drilling depth - 20 feet Drilling depth - 30 feet Tripped out to clean bit; added collar and new mud hose fitting Commenced drilling Drilling depth - 40 feet Drilling depth - 45 feet, very slow drilling Tripped out to clean bit Commenced drilling Drilling depth - 50 feet Drilling depth - 55 feet; penetrated lost circulation zone; mud viscosity 44 (Marsh-funnel viscosity in seconds); added lost circulation materials (LCM)
4/15/81	0500 0603 0955 1145 1236 1350 1445 1505 1647 1918(est) 2014 2110	Circulation restored; commenced drilling Drilling depth - 60 feet Drilling depth - 70 feet Drilling depth - 80 feet Drilling depth - 90 feet Drilling depth - 95 feet; drilling stopped to add collar Commenced drilling Drilling depth - 100 feet Drilling depth - 110 feet; very hard limestone at 105 feet Drilling depth - 120 feet Stopped drilling at 121 feet; changed mud hose Commenced drilling
4/16/81	0500	Drilling depth - 126 feet; lowered mud viscosity to 32 and tripped out of borehole; ran directional survey (<0.5° deviation)

<u>Date</u>	<u>Time</u>	<u>Activity</u>
4/16/81	0900	Started installing 20-inch ID, 312 wall, blank casing
4/17/81	0320	Casing installed; commenced pressure grouting
	0540	Grouting completed
4/20/81	1930	Tripped into borehole
	2300	Commenced drilling 17 1/2-inch borehole
4/21/81	0300	Drilling depth - 130 feet
	0345	Drilling depth - 140 feet
	0730	Drilling depth - 150 feet
	0800	Added collar; ran directional survey (<0.5° deviation)
	0852	Commenced drilling
	1140	Drilling depth - 160 feet
	1640	Drilling depth - 170 feet - tightly cemented zone, probably Anchor member of Monte Cristo limestone
	2225	Drilling depth - 180 feet
4/22/81	0029	Drilling depth - 185 feet; mud temperature increased; cuttings were warm to the touch
	0100	Stopped drilling at 188 feet; cleaned upper and lower mud pump valves
	0135	Commenced drilling
	0205	Drilling depth - 190 feet; drilling fluid temperature 78°F
	0635	Drilling depth - 204 feet; added collar and increased mud viscosity
	0800	Commenced drilling
	1115	Stopped drilling at 207 feet; serviced mud hose
	1118	Commenced drilling
	1230	Drilling depth - 210 feet
	1820	Drilling depth - 220 feet
	2230	Drilling depth - 230 feet
4/23/81	0148	Stopped drilling at 235 feet; ran directional survey (<0.5° deviation); increased mud viscosity
	0230	Commenced drilling
	0430	Drilling depth - 240 feet
	0850	Drilling depth - 250 feet
	1230	Drilling depth - 260 feet
	1735	Drilling depth - 270 feet; increased mud viscosity
	2015	Drilling depth - 280 feet
	2240	Drilling depth - 290 feet; mud viscosity at 36

<u>Date</u>	<u>Time</u>	<u>Activity</u>	
4/24/81	0130	Drilling depth - 300 feet	
	0237	Drilling depth - 305 feet; some lost circulation; increased viscosity	
	0340	Drilling depth - 310 feet	
	0415	Penetrated lost circulation zone at 313 feet; increased mud viscosity	
	0420	Complete loss of circulation; mud pit drained into borehole	
	0720	Tripped out of borehole	
	0850	Trip out completed; bit showed only minimal wear; drilling fluid level in borehole measured at 271 feet below land surface; tripped back in	
	1030	Circulation restored	
	1150	Drilling depth - 320 feet	
	1420	Drilling depth - 330 feet	
	1617	Drilling depth - 340 feet	
	2115	Drilling depth - 350 feet	
	4/25/81	0010	Penetrated lost circulation zone at 357 feet; mud viscosity 32
		0620	Circulation restored
0832(est)		Drilling depth - 360 feet	
1545		Drilling depth - 370 feet	
2145		Drilling depth - 380 feet	
4/26/81	0122	Penetrated lost circulation zone at 384 feet; increased mud viscosity	
	0515	Could not restore circulation; started drilling blind	
	0630	Stopped drilling at 386 feet; sheared universal joint bolts on rotary drive line	
	0700	Commenced drilling	
	0725	Stopped drilling at 386 feet; increased mud viscosity	
	1610	Mud viscosity at 200; still no circulation	
	1840	Commenced drilling blind	
	2130	Stopped drilling @ 387 feet	
4/27/81	0100	Started tripping out	
	0245	Completed tripping out; water-level sounding indicated dry borehole to 387 feet; inspection of bit showed what was believed to be siliceous matrix of brecciated limestone indicating drilling fluid being lost in a highly fractured zone	
	1100	Began cementing off lost circulation zone	

<u>Date</u>	<u>Time</u>	<u>Activity</u>
4/27/81	1150	Cementing completed - cement was sounded at 110 feet; viscosity at 38; tripped back into borehole to clear bridging
	1330	Penetrated bottom of cement at 240 feet; bridge collapsed and cement fell to bottom of borehole; cement allowed to set-up for 15 hours
4/28/81	0530	Commenced drilling; residual cement bridges were penetrated at 155 feet and 294 feet
	1330	Cement penetrated at 365 feet
	1410	Bedrock penetrated at 387 feet
4/29/81	0915	Drilling depth - 400 feet
	1145	Lost circulation zone penetrated at 402 feet
	1430	Commenced drilling blind
	1450	Circulation restored
	1540	Circulation lost; mud pit was drained into borehole; universal joint on drive assembly sheared and oil pump hose broke
	1820	Drilling depth - 404 feet; very slow drilling (0.5 feet/hr)
	2300	Lost circulation
	2400	Tripped out to change bits
4/30/81	0200(est)	Trip out completed; bit was very worn
	0500	Trip in completed; drill stem only went to 345 feet; old bit had lost gauge so borehole had to be reamed out with new bit
	0700	Reaming completed
	0925	Drilling depth 410 feet; mud viscosity at 55
	1425	Drilling depth-420 feet
	1910	Minor lost circulation at 426 feet
	2350	Drilling depth 430 feet
5/1/81	0210	Mud pump lost pressure at 434 feet; cleaned valves and tightened idler arm and universal joint bolts.
	0550	Drilling depth - 440 feet
	1130	Drilling depth - 450 feet
	1745	Drilling depth - 460 feet; mud viscosity at 45
	2110	Drilling depth - 470 feet
	2245	Drilling depth - 480 feet

<u>Date</u>	<u>Time</u>	<u>Activity</u>
5/2/81	0200	Drilling depth - 490 feet; harder drilling
	0550	Drilling depth - 400 feet; alternated very hard and soft formation
	0900	Drilling depth - 510 feet
	1150	Stopped drilling at 520 feet; ran direction survey (2° deviation at 520 feet, 17.5 feet of horizontal drift); mud viscosity at 40
	1400	Drilling depth - 530 feet
	1700	Drilling depth - 540 feet; mud viscosity at 40
	2110	Drilling depth - 550 feet
	2315	Drilling depth - 560 feet
	5/3/81	0420
0540		Lost circulation zone penetrated at 571 feet; increased mud viscosity
0850		Commenced drilling blind
0915		Drilling depth - 572 feet; drilled hard and slow; no circulation; mud was being lost
1155		Measured fluid level at 344 feet
1540		Drilling depth - 577 feet; fluid level measured at 347.4 feet
1840		Drilling depth - 580 feet; still drilled blind
5/4/81	0050	Drilling depth - 590 feet
	0540	Drilling depth - 595 feet; stopped drilling to run directional survey (2° deviation at 595 feet); fluid level measured at 347 feet
	0625	Commenced drilling
	0740	Drilling depth - 600 feet; still drilled blind
	1020	Drilling depth - 608 feet; tripped out and increased mud viscosity; added LCM and tried to regain circulation
	2350	Still no circulation
	5/5/81	1035
1445		Drilling depth - 610 feet
1640		Fluid level measured at 351.6 feet
5/6/81	0200	Drilling depth - 620 feet
	0850	Drilling depth - 628 feet; stopped drilling and started tripping out

<u>Date</u>	<u>Time</u>	<u>Activity</u>
5/6/81	1115	Trip out completed
	1220	Video logging crew arrived at site
	1300	Video logging began; water was too murky to log; added freshwater to borehole
	1415	Second video logging began
	1450	Video logging completed
	1530	Geophysical logging crew arrived
	1545	Logging began
	2200	Logging completed; caliper, SP&R, 3-D velocity, natural gamma, and induction log were run
5/7/81	1205	Third video logging began
	1500	Video logging completed; drilling and logging completed

A1.2.2 Bit Program

Summarized below is the bit schedule for drilling of CE-DT-5.

<u>Size Inch</u>	<u>Type</u>	<u>Date In Time</u>	<u>Date Out Time</u>	<u>Footage</u>	<u>Hours</u>
26	mill tooth	4/13/81 2015	4/16/81 0530	126	43
17.5	button	4/20/81 2144	4/26/81 2130	261	105
17.5	mill tooth	4/27/81 1220	4/29/81 2330	40	38
17.5	button	4/30/81 0550	5/6/81 0900	201	111

A1.2.3 Drilling Fluid Program

Summarized below is a chronological listing of the drilling fluid and mud viscosity additives used in CE-DT-5 for drilling and control of lost circulation. All mud products and a mud engineer were provided by NL Baroid. The information presented below is not intended to judge the performance of any Baroid product or personnel or to make any recommendation, implied or

otherwise, on the use thereof. The sole intent of the following program description is to provide documentation of drilling fluids and conditions.

<u>Date</u>	<u>Time</u>	<u>Viscosity (seconds)</u>	<u>Depth (feet)</u>	<u>Additives Used</u>
4/13/81	2100	35	Spud-in	4600 lbs. Aquagel 120 lbs. Quik-Trol 100 lbs. Soda Ash 10 gal. Con Det
4/14/81	0715	34	31	
	1000	36	39	
	1400	38	42	
	1800	38	50	
	2040		62	80 lbs. Kwik-Seal 4650 lbs. Aquagel 100 lbs. Soda Ash 21 lbs. Quik-Trol
4/15/81	0500	44	62	50 lbs. Desco
	0630		62	100 lbs Soda Ash
	0950	55	70	
	1200	43	85

	1200		608	1250 lbs. Quik-Gel
	2400		617	100 lbs. Soda Ash

APPENDIX B1.0
AQUIFER TESTING DATA

B1.0 AQUIFER TESTING DATA**B1.1 AQUIFER TESTING HISTORY**

Summarized below is a chronological description of activities during aquifer testing of well CE-DT-5, Coyote Spring Valley, T13S, R63E, Sec. 23dd.

<u>Date</u>	<u>Time</u>	<u>Activity</u>
6/19/81	0915	Pump test contractor, equipment, and crew arrived at site
	1330	Set up bailer and began bailing at CE-VF-2 using 4.5-inch diameter bailer; water level at 629 feet
	1500	Hit mud plug at 870 feet
6/20/81	0745	Resumed bailing
	1115	Changed to suction bucket to get very thick mud out of hole
	1900	Stopped bailing; sanded out approximately 170 feet
6/21/81	0815	Resumed bailing
	1610	Stopped bailing; sanded approximately 70 feet
6/22/81	0815	Took down bailing rig and moved to CE-DT-5
	1100	Static water level at CE-DT-5 at 352 feet
	1400	Commenced bailing with 6-inch bucket
	1830	Stopped bailing after 37 loads of slightly viscous, fetid, black mud.
6/23/81	0830	Resumed bailing
	1400	Accelerator cable broke
	1500	Resumed bailing
	1600	Stopped bailing after 36 loads
6/24/81	0900	Prepared to move back to CE-VF-2
	1030	Arrived at CE-VF-2
	1500	Commenced bailing; mud plug at 1060 feet; suction bucket used to get mud out
	1815	Stopped bailing

<u>Date</u>	<u>Time</u>	<u>Activity</u>
6/25/81	0815	Resumed bailing
	1220	Installed 3-inch Parshall Flumes with Stevens type F recorders at Warm Spring and Pederson Spring in upper Moapa Valley
	1815	Stopped bailing
6/26/81	0830	Resumed bailing
	0930	Installed flume at Baldwin spring
	1815	Stopped bailing; touched bottom at 1221 feet
6/27/81	0830	Resumed bailing; water was muddy; static water level at 617 feet
	1300	Stopped bailing, prepared for move to CE-DT-5
6/28/81	1000	Began preparation to run pump
	1330	Ran bowls down hole
6/29/81	0530	Installed in-hole discharge pipe, line shaft, airline, and 1 1/2-inch PVC pipe for transducer
	0900	Test engine arrived
	1100	Pump installation resumed
6/30/81	0700	Resumed installation of pump and turbine pump head assembly
7/1/81	0800	Set pump head; installed 160 feet of 10-inch x 20-foot discharge pipe
7/3/81	0800	Continued laying discharge pipe; preparation for aquifer test
	1430	Began well development; pump discharged 600 gpm with 6.5 feet of drawdown
	1600	Discharge increased to 1100 gpm with 13 feet of drawdown
	1700	Discharge increased to 1694 gpm with 26.5 feet of drawdown
	1800	Stopped development to switch to 12-inch orifice plate; Water was clear; 36°C; pH=7.05; EC=1180 umhos/cm.
	2130	Discharge increased to maximum 2727 gpm with 20 feet of drawdown; head gear had to be changed to 4:7 for the pump to deliver 3400 gpm
7/4/81	0010	Pump off; static water level at 352 feet
	1522	Continued development at 600 gpm with less than 1 foot of drawdown

<u>Date</u>	<u>Time</u>	<u>Activity</u>
	1643	Stopped pump to change orifice plates
	1720	Started pump; discharge 1220 gpm with 1.65 feet of drawdown
7/4/81	1834	Increased discharge to 1900 gpm; 5.7 feet of drawdown
	2320	Increased discharge to 2500 gpm; gray water discharged
	2340	Water clear; drawdown 11.9 feet
7/5/81	0344	Pump off; static water level at 348.5 feet
7/6/81	0830	Pulled pump head, driveline, and geardrive for installation of airline
	1300	490 feet of 1-inch galvanized pipe arrived to be installed
	1730	Completed setting galvanized pipe for transducer
7/8/81	0600	Pump crew arrived with new engine for pump
7/9/81	0100	Finished pump installation
	0415	Began pumping at 1269 gpm; water cleared after five minutes
	0450	Increased rate to 1928 gpm; 6.5 feet of drawdown
	0600	Increased rate to 2439 gpm; 11.9 feet of drawdown
	0645	Increased rate to 2967 gpm; 17.4 feet of drawdown
	0745	Increased rate to 3450 gpm; 24.4 feet of drawdown
	0923	Pump off, installed transducer down 1-inch airline
	2115	Began step drawdown test Step 1: discharged 598 gpm; 0.67 feet of drawdown
	2316	Step 2: discharged 1270 gpm; 2.70 feet of drawdown
7/10/81	0058	Step 3: discharge 1928 gpm; 6.20 feet of drawdown
	0214	Step 4: discharge 2575 gpm; 11.0 feet of drawdown
	0319	Step 5: discharge 3370 gpm; 20.5 feet of drawdown
	0457	Step 6: discharge 3980 gpm; 27.7 feet of drawdown
	0604	End of step drawdown; began recovery; removed driveline for repairs

<u>Date</u>	<u>Time</u>	<u>Activity</u>
7/11/81	0800	Installed driveline and prepared engine for pumping
	1400	Installed weir in channel to monitor infiltration of discharge
7/12/81	1041	Began constant discharge test at 3400 gpm
	1045	Weir was destroyed by force of water; water samples for pH, EC, temp. and HCO ₃ were taken every five minutes for the first hour, every 30 minutes for the next three hours, every one hour until 12 hours into test, then once every 12 hours
7/13/81	1700	Engine stopped, cause unknown
	1758	Began constant discharge test 1b
7/14/81	1330	Engine stopped running
	1340	Restarted engine
	1355	Resumed constant discharge test
	1420	Engine stopped running; water temperature at maximum reading
7/15/81	1128	Started pumping to check engine temperature
	1245	Stopped engine
7/16/81	0910	Engine mechanic arrived on site
	1745	Engine mechanic departed site
7/17/81	0730	Engine mechanic arrived on site; replaced thermostat and water pump bowl and seal
	1000	Started engine
	1130	Stopped engine
	1313	Started constant discharge test 2
7/18/81	0430	Diesel line leaking
	0530	Stop test
	2054	Start constant discharge test 3
7/19/81	-	Pumping continued
7/20/81	0710	Engine mechanic on site to check engine temperature; ranging between 198-202°F, gauge showing 210°F+
7/21/81	0730	USGS representatives on site to take water samples for isotope analysis

<u>Date</u>	<u>Time</u>	<u>Activity</u>
7/22/81	1113	Pump stopped; gear drive locked up and stopped engine
7/24/81	0610	Survey crew arrived on site to survey elevations of wells and springs
	1010	Engine mechanic arrived on site to help replace gear drive and fan on engine
	1210	Pump crew shortened drive line to fit new gear drive; changed engine oil and filters
	1800	Engine started up to test gear drive
	1929	Started constant discharge test 4
7/25/81	-	Pumping continued
7/26/81	-	Pumping continued
7/27/81	-	Pumping continued
7/28/81	0730	Leak in fuel line; test stopped
7/29/81	0000	Worked on fuel lines
	1900	Started engine
	1930	Started constant discharge test 5
7/30/81	1710	Stopped pump; fuel leak
	2200	Engine started
	2220	Started constant discharge test 6a
7/31/81	1115	Engine mechanic on site to check engine; pumping continued
8/1/81	-	Pumping continued
8/2/81	-	Pumping continued
8/3/81	0640	Water sample taken for laboratory analysis; screen installed on radiator to keep bugs out
8/4/81	-	Pumping continued
8/5/81		Pumping continued
8/5/81	1020	Engine mechanic on site to check engine
8/6/81	-	Pumping continued; cleaned engine radiator

<u>Date</u>	<u>Time</u>	<u>Activity</u>
8/7/81	- 1400	Pumping continued Transducers at CE-DT-6 pulled out of the hole; unit sent back to Long Beach for repair
8/8/81	-	Pumping continued
8/9/81	-	Pumping continued
8/10/81	- 1930	Pumping continued Severe storm; pressure transducer unit at CE-DT-4, 5 shorted out; water level measurements taken with electric sounder
8/11/81	-	Pumping continued
8/12/81	1250 1505 1511	Water samples taken for laboratory analysis Engine mechanic on site to check engine Stopped test at direction of Air Force
8/13/81	0830 1215 1245	Engine mechanic on site; checked fuel pump, replaced tachometer, and hooked up thermister to check engine tempera- ture; changed oil, filters, and lubed driveline Received Air Force direction to restart test Started constant discharge test 6b
8/14/81	-	Pumping continued
8/15/81	-	Pumping continued
8/16/81	-	Pumping continued
8/17/81	-	Pumping continued
8/18/81	-	Pumping continued
8/19/81	-	Pumping continued
8/20/81	-	Pumping continued
8/21/81	-	Pumping continued
8/22/81	-	Pumping continued
8/23/81	-	Pumping continued
8/24/81	-	Pumping continued

<u>Date</u>	<u>Time</u>	<u>Activity</u>
8/25/81	1057	Pump off; bearing on power take-off unit went out, heated, blew seal, caught on fire
	1530	Engine mechanic on site; power take-off unit to shop
8/26/81	0540	Replacement engine arrived on site
	1029	Started constant discharge test 7a with replacement engine;
8/27/81	1330	Engine mechanic arrived on site to install power take-off unit and service engine
	1420	Replacement engine stopped; safety shut-off
	1435	Started constant discharge test 7b
	1500	Replacement engine stopped again
8/28/81	1839	Started constant discharge test 8 with original engine at 3400 gpm
8/29/81	-	Pumping continued
8/30/81	-	Pumping continued
8/31/81	-	Pumping continued
	0710	Water sample taken for laboratory analysis
9/1/81	-	Pumping continued
9/2/81	-	Pumping continued
9/3/81	-	Pumping continued
9/4/81	-	Pumping continued
9/5/81	-	Pumping continued
9/6/81	-	Pumping continued
	2044	Back-up engine arrived on site (Cummins diesel)
9/7/81	-	Pumping continued
9/8/81	-	Pumping continued
9/9/81	-	Pumping continued
9/10/81	-	Pumping continued

<u>Date</u>	<u>Time</u>	<u>Activity</u>
9/11/81	- 0850 0914 1200	Pumping continued Engine mechanic arrived on site to service engine Engine turned off and serviced Constant discharge test 8 resumed
9/12/81	-	Pumping continued
9/13/81	-	Pumping continued
9/14/81	- 0700	Pumping continued Water sample taken for laboratory anal- sis
9/15/81	-	Pumping continued
9/16/81	-	Pumping continued
9/17/81	-	Pumping continued
9/18/81	-	Pumping continued
9/19/81	-	Pumping continued
9/20/81	-	Pumping continued
9/21/81	-	Pumping continued
9/22/81	-	Pumping continued
9/23/81	-	Pumping continued
9/24/81	-	Pumping continued
9/25/81	-	Pumping continued
9/26/81	-	Pumping continued
9/27/81	1800 2136	Water sample taken for laboratory anal- ysis Constant discharge test completed; pressure transducer recorder unit jammed during recovery; water-level measurements obtained with electric sounder
9/28/81	0730	Disassemble equipment; continue moni- toring recovery
9/29/81	0715	Pulled pump
