FOREWORD

This report was prepared for the Department of the Air Force, Space and Missile Systems Organization (SAMSO) in compliance with conditions of Contract No. F04704-77-C-0010, and is a geotechnical summary of the three prime Characterization sites in the Great Basin Candidate Siting Province (CSP). The three sites are Dry Lake Valley and Ralston Valley, Nevada; and Sacramento Valley, Arizona.

The report presents representative data obtained from geotechnical field investigations performed at the three sites as part of the Characterization program. The information obtained from these studies, in combination with data obtained in the Screening studies, has been used for geotechnical ranking (FN-TR-25).

1.0 INTRODUCTION

This report presents the results of geotechnical field investigations performed in the Dry Lake and Ralston Valley Characterization Sites in central Nevada and the Sacramento Valley Characterization Site in northwestern Arizona. This report presents representative data collected and analyzed for these sites. Access to the remaining data can be arranged through SAMSO/MNND, Norton Air Force Base, California.

The three sites are located in the Great Basin Candidate Siting Province (CSP), one of six provinces involved in the geotechnical Characterization studies. The location of the sites within the Great Basin CSP is shown in Figure 1. The Great Basin CSP is characterized by northeast to northwest trending elongate mountain ranges with intervening valleys. Most of the CSP lies within the state of Nevada, however, portions do extend into Utah, Arizona, California, and Idaho.

Suitable areas for deployment of MX missile systems remaining after Intermediate Screening were divided into CSPs based on similar geotechnical characteristics. The results of Intermediate Screening (FN-TR-17) indicated that existing data were not adequate in type or level of detail for follow-on geotechnical and geo-environmental evaluations, screening, site selection, and ranking studies. Therefore, the Characterization studies were developed to provide a rapid, relatively inexpensive method of gathering geotechnical data in a small area (maximum 700 nm²; 2400 km²) which is considered to be representative of a larger area within the CSP.

MX SITING INVESTIGATION
DEPARTMENT OF THE AIR FORCE - SAMS0

FIGURE
1

FUGRO NATIONAL, INC.

Emphasis was placed on the collection of information allowing characterization of geological units with respect to the construction aspects of MX missile basing options. Objectives of the Characterization studies were to obtain data that address the following geotechnical aspects:

- o Surficial geology and terrain
- o Subsurface conditions
- o Geophysical properties
- o Engineering properties

Although the program originally emphasized data collection for the trench and horizontal shelter basing modes, the data were utilized for evaluation of the vertical shelter basing mode as well. Characterization was, therefore, a refinement of the screening process whereby the necessary geotechnical information was developed to support the broader MX system design activities that were taking place concurrently and to provide a basis for geotechnical ranking of the CSPs for different basing modes.

Five Characterization sites (three prime and two supplemental) were selected in the Great Basin CSP (Figure 1), representing a total investigated area of less than ten percent of all suitable area within the CSP. Field activities in the two supplemental sites were terminated due to adverse weather conditions. Therefore only the three prime sites are discussed in this report. The Characterization Site selection process began with a delineation of geotechnically similar areas within each CSP having analogous depositional and geologic histories, rock and

water depths, and tectonic settings. Once these areas had been identified, non-geotechnical factors were applied to delineate the actual Characterization site boundaries. These non-geotechnical selection factors included access, proximity to support facilities, environmental sensitivities, and local logistical requirements.

Geologic, geophysical, and soils engineering techniques were used to determine the surface and subsurface geotechnical conditions in Dry Lake, Ralston, and Sacramento Valleys. These include a combination of the following:

- o Analysis of available data
- o Aerial photo interpretation of surficial geologic units utilizing black and white stereographic pairs at a ~~scale~~
Scale of approximately 1:60,000
- o Geologic field investigation to check aerial photo interpretation and to determine physical properties of the surficial units at selected field stations
- o Shallow and deep seismic refraction, downhole seismic velocity, and electrical conductivity surveys to obtain subsurface profile information
- o Gravity and ground magnetic surveys to aid in interpretation of basin configuration
- o Drilling and trenching to determine subsurface characteristics and obtain soil samples
- o Laboratory testing of soil samples to determine engineering properties

The Battle Mountain, Ely, and Kingman district offices of the U.S. Bureau of Land Management were contacted for access to the sites. Prior to initiating any field work, an archeological and environmental inspection was conducted at each site to ensure minimal impact to the local environment and to avoid damage to archeologic and historic sites. To further minimize potential impacts, all field activities were performed adjacent to existing roads or other previously disturbed areas.

2.0 DRY LAKE VALLEY SITE

The Dry Lake Valley Characterization Site covers an area of 251 nm² (861 km²) in central Lincoln County, Nevada. The site is bounded by mountain ranges on the east, north, and west, and is open to Delamar Valley on the south. U. S. Highway 93 forms the southern boundary of the site and is the only paved road in the vicinity. A network of graded roads and four-wheel drive trails provide access within the site.

2.1 SCOPE OF INVESTIGATION

Scope of geologic, geophysical, and soils engineering field activities performed at the site and laboratory tests performed on soil samples from the site is presented in Table 1. Detailed information about the soils engineering field activities (18 borings and eight trenches) is summarized in Tables 2 and 3. Locations of all the field activities are shown in Figure 2.

2.2 SURFICIAL GEOLOGY AND TERRAIN

Alluvial fan deposits of younger and intermediate age are the predominant surficial geologic units within the Characterization site (Figure 2). The younger fan deposits cover approximately 42 percent of the area while the intermediate fan deposits cover 26 percent. Playa deposits cover approximately six percent of the surface. Although these playa deposits do not represent a large percentage of the surface area, they are generally of great thickness and interfinger with alluvial deposits in the subsurface. Playa deposits are located in the valley center with the alluvial fan deposits present between the playa and mountain fronts.

TABLE
 3

FUGRO NATIONAL, INC.

ENCLOSURE 1
map of the area in Figure 5

The alluvial fan deposits are typically silty sands with gravel, ranging from sandy gravels near the mountain front to sandy silts near the playa. Playa deposits are generally clayey silts. These three units along with the remaining surficial units are described in Table 4.

Surface slopes and depths of drainage incision vary with geologic units, both generally increasing with proximity to the mountain fronts (Table 4). Maximum surface slope is ten percent with typical slopes of four percent. Maximum depths of incision (excluding older alluvial fan deposits) are 15 feet (5 m) with typical depths of five feet (1.5 m).

2.3 SUBSURFACE CONDITIONS

2.3.1 Soil Profiles

The composition of soils with depth is illustrated by the soil profiles shown in Figures 3 and 4. The dominant valley soils are silty sands and gravelly sands, which interbed with sandy gravels near the mountain fronts and clayey silts near the valley center. Cobbles and boulders are occasionally found near the mountain fronts and some plastic clays are encountered in the playas. Cementation of the soils varies with soil type and age, generally increasing with age of soil. Sandy soils with less than five percent fines were generally uncemented to weakly cemented, often caving in unshored trenches.

2.3.2 Depth to Shallow (<150 ft; <46 m) Rock and Water

Figure 5 shows the portions of the Dry Lake site in which rock (seismic velocity >7,000 fps; 2134 mps) and water are estimated to be encountered within a depth of 150 feet (46 m) below the ground surface. Shallow rock comprises approximately 20 percent of the site based on data and interpretation from borings, seismic surveys, gravity surveys, surface outcrops, topography, geologic maps, and other available data. Ground water is nowhere less than 150 feet (46 m) below the surface and probably greater than 300 feet (91 m) based on information from five wells and regional data.

2.3.3 Basin Configuration

Data from deep seismic refraction, gravity, and ground magnetic surveys were used in determining the basin configuration illustrated in Figures 5 and 6. Deep seismic data indicate a layered relationship of basin-fill deposits and/or younger volcanic rocks. Gravity survey data indicate the greatest depth to Paleozoic carbonate and clastic bedrock units to be approximately 6200 feet (1890 m) below the surface in the area of the generalized geologic cross-section (Figures 5 and 6). The basin is bounded on the east, west, and north by steep gradients in basement topography typical of those associated with normal faults. A fault scarp exposed along the east side of the valley coincides with an inferred basement fault, with displacement down on the basinward side. Planated rock shelves, covered by approximately 150 feet (46 m) of basin-fill deposits are inferred along the eastern and western valley margins. The distal limits of these rock

shelves are located near the surface projection of the basement faults. Rock exposures and shallow (<150 ft; 46 m) rock do not occur basinward of these faults.

2.4 GEOPHYSICAL PROPERTIES

Results of shallow and deep seismic refraction surveys and down-hole velocity surveys are presented in Tables 5, 6, and 7, respectively. Shallow seismic refraction results (Table 5) indicate dipping and laterally discontinuous velocity horizons. Deep seismic refraction results (Table 6) indicate discontinuous velocity horizons probably due to an interfingering of basin-fill deposits with younger volcanic rocks or other basin-fill deposits. The compressional wave velocities from downhole velocity surveys (Table 7) do not correspond with those from shallow seismic refraction (Table 5) due to the anisotropy of the ground and method of measurement.

2.5 ENGINEERING PROPERTIES

Engineering properties of the subsoils representing the various geologic units were determined from laboratory tests. The tests included the following; classification, consolidation, shear strength, compaction, CBR, and chemical. The range of engineering properties and compressional wave velocities of the predominant geologic units is presented in Table 8.

Younger and intermediate alluvial fan deposits are combined into one unit since they could not be differentiated at depth. In addition, these two units have similar grain-size and engineering properties. Alluvial fan deposits consist predominantly of

* If no refracting interface or layer with a velocity greater than 7000 fps (rock/rock-like material) was detected, a rock exclusion depth calculation was performed to determine the minimum depth at which rock could occur.

dense to very dense silty sands and sandy gravels, which are slightly compressible and have moderately high shear strengths. Playa deposits are composed primarily of stiff to very stiff silts and clays, which are moderately compressible and have moderate shear strengths.

The site soils generally are neither expansive nor collapsible. Range of gradation of the two geologic units is shown in Figure 7. Results of chemical tests on soils samples are presented in Table 9. The test results indicate that sulfate attack of soils on concrete will be "positive" in some areas of the site.

Representative logs of three borings and three trenches from the site are contained in Appendix B. Results of the shear strength and CBR tests performed on soil samples from the site and a summary of all the laboratory tests performed on soil samples obtained from boring DL-B-12 are also included in Appendix B.

3.0 RALSTON VALLEY SITE

The Ralston Valley Characterization Site covers an area of 182 nm² (624 km²) in western Nye County, Nevada. The site is bounded by mountain ranges on the east and west, Nellis Bombing and Gunnery Range on the south, and is open to the northern part of Ralston Valley on the north. U. S. Highway 6 and State Highway 8A provide paved highway access through the site while graded roads and four-wheel drive trails provide access within the site.

3.1 SCOPE OF INVESTIGATION

Scope of geologic, geophysical, and soils engineering field activities performed at the site and laboratory tests performed on soil samples from the site are presented in Table 10. Detailed information about the soils engineering field activities (15 borings and eight trenches) is summarized in Tables 11 and 12. Locations of all the field activities are shown in Figure 8.

3.2 SURFICIAL GEOLOGY AND TERRAIN

Alluvial fan deposits of younger and intermediate age are the predominant surficial geologic units within the Characterization site (Figure 8). The younger fan deposits cover approximately 23 percent of the area while the intermediate fan deposits cover 18 percent. Undifferentiated non-rock deposits, consisting of fluvial, alluvial, and playa and/or lacustrine deposits cover 24 percent of the area. These non-rock units were not differentiated due to the small scale (1:62,500) of mapping. Playa deposits cover approximately three percent of the surface.

TABLE
12

FUGRO NATIONAL, INC.

Twenty-one percent of the area consists of mixed playa and undifferentiated non-rock deposits. The large percentage (45%) of the area mapped as undifferentiated non-rock deposits or mixed playa and undifferentiated non-rock deposits is due to the broad, flat topography of the site. Playas located near the valley center and alluvial deposits located between the playa and the mountain front form an interfingering stratigraphic sequence.

Alluvial fan deposits are typically silty sands with gravel, ranging from sandy gravels near the mountain front to sandy silts near the playas. Playa deposits are generally silts. All the surficial geologic units are described in Table 13.

The maximum surface slope is ten percent but typical surface slope is only three percent. Depths of drainage incision (excluding older alluvial fan deposits) range from zero to 15 feet (0-5 m) with typical depths of five feet (1.5 m).

3.3 SUBSURFACE CONDITIONS

3.3.1 Soil Profiles

The soil profiles shown in Figures 9 and 10 illustrate the composition of soils with depth. Silty sands and gravelly sands are the dominant valley soils, and are interbedded with clayey silts near the valley center and sandy gravels near the mountain fronts. Cobbles and boulders are found near the mountain fronts. Cementation of the soils varies with soil type and age, generally increasing with age of soil. Sandy

soils with less than five percent fines were generally uncemented to weakly cemented, often caving in unshored trenches.

3.3.2 Depth to Shallow (<150 ft; <46 m) Rock and Water

Figure 11 shows the portion of the Ralston Valley site in which rock (seismic velocity greater than 7000 fps; 2134 mps) and water are estimated to be within a depth 150 feet (46 m) below the ground surface. The portion of shallow rock area is approximately 15 percent of the site area. This analysis is based on data and interpretation from borings, seismic surveys, gravity surveys, surface outcrops, topography, and geologic maps. Depth to ground water is generally greater than 200 feet (61 m) below the surface except for an area near the northern site boundary (location of Tonopah well field used for domestic water supply) where ground-water levels range from 10 to 150 feet (3 to 46 m). The east-west ground-water barrier in this northern area does not show on the gravity contour map, and may represent interfingering of volcanic units and/or basin-fill deposits or an east-west trending intrusive body. Data in the Ralston site south of the Tonopah well field are from four wells and regional information.

3.3.3 Basin Configuration

The basin configuration was interpreted using deep seismic refraction, gravity and ground magnetic survey data. Deep seismic data indicate interbedding of the basin-fill deposits and/or volcanic rock units. The greatest depth to bedrock is approximately 7400 feet (2257 m) below the surface in

the area of L1 (Figure 11) along the generalized geologic cross-section (Figure 12). Cretaceous and early Tertiary volcanic rocks are the predominant bedrock unit defined in the gravity contour map. The basin is bounded on the east by steep gradients in basement topography typical of those associated with normal faults. No basement rocks are present at the surface west of this fault and a pediment is inferred east of the fault. The basin center is interpreted as a collapsed caldera overlain by younger volcanic rocks and basin-fill deposits (Figure 12). The subsurface basin configuration is illustrated in Figures 11 and 12.

3.4 GEOPHYSICAL PROPERTIES

Results of shallow and deep seismic refraction surveys and downhole velocity surveys are presented in Tables 14, 15, and 16. Shallow seismic refraction results (Table 14) indicate a low velocity surficial layer overlying a zone of higher velocity horizons. Borings adjacent to the lines indicate that the change in velocity is probably due to increased consolidation of the soil and not due to a change in lithology. Deep seismic refraction results (Table 15) indicate the bedrock depth within the valley. The compressional wave velocities from downhole velocity surveys (Table 16) do not correspond with those from shallow seismic refraction (Table 14) due to the anisotropy of the ground and method of measurement.

3.5 ENGINEERING PROPERTIES

Laboratory tests were performed to determine the engineering properties of soil samples obtained from the various geologic

units. Laboratory analysis consisted of classification tests, consolidation tests, shear strength tests, compaction and CBR tests, and chemical tests. Table 17 presents the range of engineering properties and compressional wave velocities of predominant geologic units.

Younger and intermediate alluvial fan deposits are combined into one unit since they have similar grain-size and engineering properties, and could not be differentiated at depth. These deposits consist predominantly of dense to very dense silty sands and sandy gravels, which are slightly compressible and have moderately high shear strengths. Playa deposits are composed primarily of stiff to very stiff silts and clays, which are moderately compressible and have moderate shear strengths.

In general, the site soils are neither expansive nor collapsible. Figure 10 shows the range of gradation of the geologic units. Table 18 shows the results of chemical tests on soil samples, which indicate that sulfate attack of soils on concrete will be "positive" in some areas of the site.

Representative logs of three borings and three trenches from the site are contained in Appendix C. Shear strength and CBR test results, as well as a summary of all the laboratory tests performed on soil samples obtained from boring RV-B-6, are also included in Appendix C.

4.0 SACRAMENTO VALLEY SITE

The Sacramento Valley Characterization Site covers an area of 360 nm² (1235 km²) southwest of Kingman in western Mojave County, Arizona. The site consists of two contiguous valleys, the Sacramento Valley to the east and the Mojave Valley to the west. The Sacramento Valley site is bounded by State highway 68 on the north, by the Hualapai Mountains and longitude 114 00' W. on the east, and the Black and Mojave Mountains on the west and south. The Mojave Valley area was found unsuitable after preliminary field investigations and, except for the surficial geology map, the area is not considered in this report. Paved highway access is provided by State highway 68, Interstate 40, and the Kingman-Oatman Road. Graded roads and four-wheel drive trails are also present within the site.

4.1 SCOPE OF INVESTIGATION

Scope of geologic, geophysical, and soils engineering field activities performed at the site and laboratory tests performed on soil samples from the site is presented in Table 19. Detailed information about the soils engineering field activities (11 borings and eight trenches) is summarized in Tables 20 and 21. Locations of all the field activities are shown in Figure 14.

4.2 SURFICIAL GEOLOGY AND TERRAIN

Alluvial fan deposits of intermediate age are the predominant surficial geologic unit at the site, covering approximately 74 percent of the area. Of this amount, 17 percent is covered by a thin (generally less than 20 feet; 6 m) veneer of younger

alluvial fan deposits. Younger alluvial fan deposits greater than 20 feet (6 m) thick cover another nine percent of the area. The site is characterized by an open drainage system and contains no playa deposits.

The intermediate alluvial fan deposits are typically silty gravelly sands ranging from silty sands to sandy gravels with cobbles and boulders. Younger alluvial fan deposits are generally silty sands with local gravel. The surficial geologic units are described in Table 22.

The maximum surface slope is ten percent with typical slopes of four percent. Depths of drainage incision (excluding older alluvial fan deposits) range from zero to 30 feet (0 to 9 m) with typical depths of ten feet (3 m).

4.3 SUBSURFACE CONDITIONS

4.3.1 Soil Profiles

The composition of soils with depth is illustrated by the soil profiles shown in Figures 15 and 16. The dominant valley soils are silty sands and gravelly sands, which interbed with sandy gravels near the mountain fronts. Cobbles and boulders are occasionally found near the mountain fronts. Cementation of the soils generally increases with age of soil. Sandy soils at shallow depths are generally uncemented to weakly cemented, often caving in unshored vertical trench excavations.

4.3.2 Depth to Shallow (<150 ft; <46 m) Rock and Water

Figure 17 shows portions of the site in which rock (seismic

velocities greater than 7000 fps; 2134 mps) is estimated to be encountered within a depth 150 ft (46 m) below the ground surface. This area with shallow rock covers approximately ten to 15 percent of the area. This analysis is based on data and interpretation from borings, seismic surveys, gravity surveys, surface outcrops, topography, and geologic maps. Ground water is nowhere less than 150 feet (46 m) below the surface and generally greater than 300 feet (91 m) based on regional water well data.

4.3.3 Basin Configuration

Data from seismic refraction and gravity surveys were used in interpreting basin configuration. Gravity data indicate greatest depth to basement to be approximately 10,000 feet (3048 m) below the surface near the southeastern boundary of the site (Figure 17). The basement surface on which the gravity is interpreted is probably a Precambrian surface below the basin-fill deposits though locally, this interpretation may be due to a dense volcanic surface. The cross-section (Figure 18) is drawn in the northern part of the site where the depth to basement is only 6000 feet (1829 m). The basin in this area is bounded by gravity gradients similar to those associated with normal faults, with relative movement down on the basinward side. The basin configuration is illustrated in Figures 17 and 18.

4.4 GEOPHYSICAL PROPERTIES

Results of shallow seismic and conductivity measurements are presented in Tables 23 and 24, respectively. Seismic compressional wave velocities ranged from 990 to 8540 fps (302 to 2600 m/s).

EXPLANATION

NOTES:

1. The cross section is generally representative of subsurface conditions within the band shown on the location map. Due to the limited density of available data and the sparseness of newly acquired data, the subsurface conditions are highly interpretive.
2. For a detailed description of geologic units see Table A-1.

2603 mps). The low velocity (2000 fps; 610 mps) surficial layer was less than ten feet (3 m) thick. Velocities greater than 7000 fps or 2134 mps (considered rock) were only observed at depths of 71 and 38 feet (22 and 12 m) at SV-S-6 and SV-S-7, respectively. Average electrical conductivities for the upper 50 feet (15 m) of soil ranged from 0.004 to 0.022 mhos/m. All exceeded the minimum value of 0.004 mhos/m specified in the Fine Screening criteria except at SV-R-6 which was equal to the minimum.

4.5 ENGINEERING PROPERTIES

Engineering properties of the subsoils were determined from laboratory tests. The tests included the following; classification, shear strength, compaction, CBR, and chemical. The range of engineering and geophysical properties of predominant geologic units is presented in Table 25.

Younger and intermediate alluvial fan deposits are combined into one unit since they could not be differentiated at depth. In addition, these two units have similar grain-size and engineering properties. These alluvial fan deposits consist predominantly of dense to very dense silty sands and sandy gravels possessing moderately high shear strengths. Range of gradation of the alluvial fan deposits is shown in Figure 19. Results of chemical tests on soil samples are presented in Table 26. The test results indicate that sulfate attack of soils on concrete will be "positive" in most areas of the site.

Representative logs of three borings and three trenches from the site are contained in Appendix D. Results of the shear strength

ENGINEERING AND GEOPHYSICAL PROPERTIES		Intermediate and younger alluvial fan deposits (A5i and A5y)

5.0 DISCUSSION

Analysis of the geotechnical data shows similar and dissimilar features between all three sites. In general, Dry Lake and Ralston valleys are similar and may be used to characterize an area between and around the sites in central Nevada. The Sacramento Valley site is significantly different from Dry Lake and Ralston valleys and can be used to characterize scattered areas of the Great Basin CSP in Arizona and Nevada. Similarities between Dry Lake and Ralston valleys are:

- o Younger and intermediate alluvial fan deposits are the predominant surficial geologic units (younger fans being dominant).
- o Playa deposits, though not extensive on the surface, are a significant unit due to their thickness and central valley location.
- o The basins have closed drainage.
- o These valleys are generally down-dropped (relative to mountains) structural blocks bounded by potentially active faults.
- o The engineering characteristics of the geologic units at the two sites are similar, however, there are differences between the areal extent of these units at each site.

Some dissimilar features between Dry Lake and Ralston are:

- o Large areas of undifferentiated non-rock and playa deposits exist in the Ralston site (result of very low relief near valley center).

- o Although no eolian sand deposits are present in Dry Lake Valley, they are present in Ralston Valley and may be encountered locally in areas between and adjacent to the sites.
- o The fine grained soils in Dry Lake Valley are slightly more plastic but less extensive than those of Ralston Valley.

Sacramento Valley exhibits properties different from those in Dry Lake and Ralston valleys. The major differences are:

- o Sacramento Valley displays open drainage (the first four differences that follow can be attributed to this basic characteristic).
- o Sacramento has no playa deposits.
- o The ratio of areas of intermediate to younger alluvial fan deposits in Sacramento is greater by an order of magnitude (7.8 for Sacramento compared to 0.7 and 0.9 for Dry Lake and Ralston, respectively).
- o Depth of drainage incision is generally greater in Sacramento.
- o Surface slope is generally greater in Sacramento.
- o Alluvial deposits of Sacramento (due to granitic source) contain more sand.

Some features similar to Sacramento, Dry Lake, and Ralston valleys are:

- o Alluvial fan deposits are the predominant unit.
- o Basins are elongate, generally north-trending structural depressions with bounding normal faults (i.e. grabens).

Geotechnical conditions at the Dry Lake and Ralston sites are representative of approximately 25 percent of the CSP while conditions at the Sacramento site are representative of about eight percent of the area. Approximately two thirds of the CSP is not characterized by these three sites and a variety of conditions exist throughout this remaining portion of the CSP. For example, south and east of Dry Lake the area is typified by open drainages down-cutting into Tertiary lacustrine deposits. Northeast of Dry Lake, the area was inundated by Pleistocene Lake Bonneville and is typified by Pleistocene lacustrine deposits and associated gravel shorelines.

6.0 CONSTRUCTION CONSIDERATIONS

In this section, geotechnical factors and conditions applicable to construction of the MX system are discussed. The three basing mode concepts considered are vertical shelter, in-line hybrid trench, and horizontal shelter.

The important geotechnical factors for a vertical shelter are roads (primary and interconnecting), drainage crossings, and excavation of shelters. For the in-line hybrid trench, important geotechnical factors are excavation and backfill, roads (primary and temporary), drainage crossings, and aggregates for roads and concrete. For the horizontal shelter, roads and drainage crossings are the important geotechnical factors. A brief summary of the applicable geotechnical factors is presented in the following paragraphs.

- o Terrain - Surficial slopes are typically less than four percent, requiring little preconstruction grading for roads and trenches. Depths of drainage incision are generally five to ten feet (1.5 to 3 m) minimizing the need for major drainage structures for roads and trenches.
- o Roads - Few roads exist at the sites and therefore, a network of roads will have to be constructed. Approximately 90 percent of the surficial deposits are coarse-grained soils consisting of gravelly sands, silty sands, and sandy gravels. These soils have good to excellent sub-grade characteristics when compacted, resulting in cost-effective road sections.

- o Excavation - Most of the subsurface soils are dense, weakly to moderately cemented, and possess moderately high shear strength. Except in areas close to mountain fronts, compressional wave velocities range from 1000 to 5000 fps (305 to 1524 mps) up to depths of 150 feet (46 m) below the ground surface, indicating good excavatability. The soils are suitable for excavation of: vertical shelters by augers, continuous trenches (cast-in-place trench construction) by an MX trencher, and horizontal shelters using conventional equipment. In approximately 20 percent of the area, the excavation walls of a vertical shelter may be unstable, requiring slurry or other techniques to support them. Approximately five percent of the area has zones of concentrated cobbles and boulders where an MX trencher will not be able to excavate a trench suitable for cast-in-place construction.

Depth to rock is greater than 150 feet (46 m) over approximately 80 to 85 percent of the sites, therefore, additional expense for excavation of vertical shelters is minimal.

Depth to ground water is greater than 300 feet (92 m) in Dry Lake and Sacramento valleys and greater than 200 feet (61 m) in 90 percent of Ralston Valley, thus, ground-water problems during excavation are expected to be minimal.

- o Backfill - Subsurface soils are generally suitable for backfill and compaction in trench excavations; minimum compactive effort will be required. Backfill will have to be imported from within the sites for areas of concentrated cobbles and boulders.

- o Aggregates and Water - Sufficient quantities of aggregates and water required for roads and concrete are available within and/or adjacent to the sites, thus minimizing haul costs.

7.0

CONCLUSIONS

In summary, Dry Lake, Ralston, and Sacramento sites present favorable geotechnical conditions for deployment of any of the three present MX basing mode concepts. Geotechnical conditions from these three sites can be extrapolated to approximately 33 percent of the Great Basin CSP.

EXPLANATION OF GEOLOGIC UNITS	A-1
UNIFIED SOIL CLASSIFICATION SYSTEM	A-2

GLOSSARY OF TERMS

ACTIVITY NUMBER - A designation composed of the valley abbreviation followed by the activity type and a unique number; may also be used to designate a particular location in a valley.

AEROMAGNETIC DATA - Magnetometer observations made from an airplane.

ALLUVIAL BASIN - A lowland area, generally between uplifted mountain blocks, filled with alluvial deposits.

ALLUVIAL FAN - A low, outspread, relatively flat to gently sloping mass of alluvium, shaped like an open fan or a segment of a cone, deposited by a stream (especially in a semiarid region) at the place where it issues from a narrow mountain valley upon a plain or broad valley. It is steepest near the mouth of the valley where its apex points upstream, and it slopes gently and convexly outward with gradually decreasing gradient.

ALLUVIAL FAN DEPOSITS - Alluvium deposited by a stream or other body of running water as a sorted or semisorted sediment in the form of a cone or fan at the base of a mountain slope.

ALLUVIAL PLAIN - A level or gently sloping tract or a slightly undulating land surface produced by extensive deposition of alluvium, usually adjacent to a river that periodically overflows its banks; it may be situated on a flood plain, a delta, or an alluvial fan.

ALLUVIUM - A general term for unconsolidated clay, silt, sand, gravel, and boulders deposited during relatively recent geologic time by a stream or other body of running water as a sorted or semisorted sediment in the bed of a stream or on its flood plain or delta, or as a cone or fan at the base of a mountain slope.

ANOMALY - 1) A deviation from uniformity in physical properties; especially a deviation from uniformity in physical properties of exploration interest. 2) A portion of a geophysical survey which is different in appearance from the survey in general.

AQUIFER - A permeable saturated zone below the earth's surface capable of conducting and yielding water as to a well.

GLOSSARY OF TERMS (Cont.)

ARKOSIC SANDSTONE - A sandstone with considerable feldspar, such as one containing minerals from coarse-grained quartzofeldspathic rocks (granites, granodiorites, medium or high-grade schists) or from older, highly feldspathic sedimentary rocks; specifically a sandstone containing more than 25% feldspar and less than 20% matrix material of clay, sericite, and chlorite.

ARRIVAL - An event; the appearance of seismic energy on a seismic record; a line-up of coherent energy signifying the arrival of a new wave train.

ATTERBERG LIMITS - A general term applied to the various tests used to determine the various states of consistency of fine grained soils. The four states of consistency are solid, semisolid, plastic, and liquid.

Liquid limit (LL) - The water content corresponding to the arbitrary limit between the liquid and plastic states of consistency of a soil (ASTM D423-66).

Plastic limit (PL) - The water content corresponding to an arbitrary limit between the plastic and the semisolid states of consistency of a soil (ASTM D424-59).

Plasticity index (PI) - Numerical difference between the liquid limit and the plastic limit.

BASIN-FILL MATERIAL/BASIN-FILL DEPOSITS - Heterogenous detrital material deposited in a sedimentary basin.

BEDROCK - Rock with a seismic p-wave velocity of 7000 ft (2333 m) per second or more.

BOUGUER ANOMALY - The residual value obtained after latitude, elevation and terrain corrections have been applied to gravity data.

BOULDER FIELD - Five or more rocks, each with diameters of 6 ft or more occurring within an acre.

BULK SAMPLE - A disturbed soil sample (bag sample) obtained from cuttings brought to the ground surface by a drill rig auger or obtained from the walls of a trench excavation.

c - Cohesion (Shear strength of a soil not related to inter-particle friction).

CALICHE - Gravel, sand or other material cemented principally by calcium carbonate.

GLOSSARY OF TERMS (Cont.)

CALIFORNIA BEARING RATIO (CBR) - A test performed on a specifically prepared soil sample which is useful in the design of road pavement to be supported by the soil tested (ASTM D1833-73). The load is applied on the penetration piston which is penetrated into the soil sample at a constant penetration rate. The bearing ratio reported for the soil is normally the one at 0.1 inches (2.5 mm) penetration.

CANDIDATE - One of some group of regions, areas or sites being considered for MX deployment. Removal of candidate from a specifically named region, area or site term indicates selection by SAMSO/MNND.

CANDIDATE DEPLOYMENT AREA (CDA) - An area encompassing between 500 and 1000 square nautical miles of potentially suitable land with either naturally or artificially defined boundaries designated for convenience of study, discussion and data depiction. The candidate deployment area could be composed of two to four parcels and should have a specific place name description.

CANDIDATE DEPLOYMENT PARCEL (CDP) - An area of 150 to 500 square nautical miles potentially suitable for MX siting which, when aggregated with others, forms a Candidate Deployment Area. Each parcel should have a specific geographic description. (In the Basin and Range Physiographic province a parcel may correspond to a geographic valley and in Texas to some agri-economic unit.)

CANDIDATE DEPLOYMENT SITE (CDS) - A non-specific (i.e. not finally approved) site proposed for some element of the MX system within a chosen deployment area (i.e. trench or shelter site).

CANDIDATE SITING PROVINCE (CSP) - An area potentially suitable for deployment of the MX system generally encompassing more than 6000 square nautical miles which, in a broad sense, is homogeneous with respect to most of the important characteristics governing siting of a total MX system.

CANDIDATE SITING REGION (CSR) - Potentially suitable area between 4000 and 6000 square nautical miles within one, or encompassing portions of more than one, candidate siting province which allows for full MX deployment.

GLOSSARY OF TERMS (Cont.)

- CAPABLE (fault) - Movement at or near the surface at least once in the past 35,000 years, and/or more than once in the past 500,000 years, (Nuclear Regulatory Commission).
- CAPROCK - A resistant, moderately to strongly cemented caliche layer forming a "cap" over less resistant layers.
- CD TRIAXIAL SHEAR - A type of test to measure the shear strength of an undisturbed soil sample
- CLOSED BASIN - A catchment area draining to some depression or lake within its area, from which water escapes only by evaporation.
- COARSE-GRAINED - A term which applies to a soil of which more than one-half of the soil particles, by weight, are larger than 0.075 mm in diameter (passing the No. 200 U.S. size).
- COARSER-GRAINED - A term applied to alluvial fan deposits which are predominantly composed of material larger than 3 inches (76 mm) in diameter.
- COLLUVIAL DEPOSITS - A general term applied to any loose, heterogenous, and incoherent mass of soil material or rock fragments deposited chiefly by dislodgement and downslope transport of the material under the direct application of gravitational body stresses. Material is usually found at the base of a steep slope or cliff.
- COMPACTION TEST - A type of test to determine the relationship between the moisture content and density of a soil sample which is prepared in compacted layers at various water contents (ASTM D1557-70).
- COMPRESSIBILITY - Property of a soil pertaining to its susceptibility to decrease in volume when subjected to load.
- COMPRESSIONAL WAVE - An elastic body wave in which particle motion is in the direction of propagation; the type of seismic wave assumed in conventional seismic exploration. Also called P-wave, dilatational wave, and longitudinal wave.
- CONSOLIDATION TEST - A type of test to determine the compressibility of a soil sample. The sample is enclosed in the consolidometer which is then placed in the loading device. The load is applied in increments at certain time intervals and the change in thickness is recorded.

GLOSSARY OF TERMS (Cont.)

CONTERMINOUS UNITED STATES - The contiguous 48 states.

CORE SAMPLE - A cylindrical sample obtained with a rotating core barrel with a cutting bit at its lower end. Core samples are obtained from indurated deposits and in rock.

DEBRIS FLOW - A high-density flow of mud containing abundant coarse-grained materials (boulders, cobbles, gravel, sand) that frequently result from an unusually heavy rain.

DEGREE OF SATURATION - Ratio of volume of water in soil to total volume of voids.

DETECTOR - See GEOPHONE.

DIRECT SHEAR TEST - A type of test to measure the shear strength of a soil sample where the sample is forced to fail on a predetermined plane.

DISSECTION/DISSECTED (alluvial fans) - The cutting of stream channels into the surface of an alluvial fan by the movement (or flow) of water.

DISTAL - That portion of an alluvial deposit farthest from its point of origin.

DRY UNIT WEIGHT/DRY DENSITY - Weight per unit volume of the solid particles in a soil mass.

ELECTRICAL CONDUCTIVITY - Ability of a material to conduct electrical current

ELECTRICAL RESISTIVITY - Property of a material which resists flow of electrical current

ENTRENCH - The process whereby a stream erodes downward to form a trench.

EOLIAN - A term applied to materials which are deposited by wind.

EPHEMERAL(stream) - A stream in which water flow is discontinuous and of short duration.

EXTERNAL DRAINAGE - Stream drainage system whose downgradient flow is unrestricted by any topographic impediments.

EXTRUSIVE (rock) - Igneous rock that has been ejected onto the earth's surface (e.g., lava, basalt, rhyolite, andesite; detrital material, volcanic tuff, pumice).

GLOSSARY OF TERMS (Cont.)

- FAULT** - A plane or zone of rock fracture along which there has been displacement.
- FAULT BLOCK MOUNTAINS** - Mountains that are formed by normal faulting in which the surface crust is divided into structural, partially to entirely fault-bounded blocks of different elevations.
- FINE-GRAINED** - A term which applies to a soil of which more than one-half of the soil particles, by weight, are smaller than 0.075 mm in diameter (passing the No. 200 U.S. size sieve).
- FINER-GRAINED** - A term applied to alluvial fan deposits, which are composed predominantly of material less than 3 inches (76 mm).
- FLOODING/LOW ENERGY FLOW** - Flood waters flowing on a slope of low gradient.
- FLUVIAL DEPOSITS** - Material produced by river action; generally loose, moderately well-graded sands and gravel.
- FORMATION** - A mappable assemblage of rocks characterized by some degree of homogeneity or distinctiveness.
- FREE AIR ANOMALY** - Gravity data which have been corrected for latitude and elevation (free air correction) but not for the density of rock between the datum and the plane of measurement (Bouguer correction).
- FUGRO DRIVE SAMPLE** - A 2.50 inch (6.4 cm) diameter soil sample obtained from a drill hole with a Fugro Drive Sampler. The Fugro drive sampler is a ring-lined barrel sampler containing 12 one-inch (2.54 cm) long brass sample rings. The sampler is advanced into the soil using a drop-hammer.
- GAMMA** - A unit of magnetic-field intensity. A gamma is 10^{-5} oersteds; sometimes expressed (incorrectly) as 10^{-5} gauss with which it is numerically equal.
- GEO MORPHOLOGY** - The study, classification, description, nature, origin, and development of present landforms and their relationships to underlying structures, and of the history of geologic changes as recorded by these surface features.
- GEOPHONE** - The instrument used to transform seismic energy into electrical voltage; a seismometer, jug, or pick-up.

GLOSSARY OF TERMS (Cont.)

GRAIN-SIZE ANALYSIS (GRADATION) - A type of test to determine the distribution of soil particle sizes in a given soil sample. The distribution of particle sizes larger than 0.075mm (retained on the No. 200 sieve) is determined by sieving, while the distribution of the particle sizes smaller than 0.075 mm is determined by a sedimentation process, using a hydrometer.

GRAVEL - Particles of rock that pass a 3-in. (76.2 mm) sieve and retained on a No. 4(4.75 mm) sieve

GRAVITY - The force of attraction between bodies because of their mass. Usually measured as the acceleration of gravity.

GRAVITY GRADIENT - The partial derivative of the acceleration of gravity with respect to distance in a particular direction, for which purpose the acceleration of gravity is considered as a scalar.

INTERIOR DRAINAGE - Stream drainage system that flows into a closed topographic low (basin).

INTRUSIVE (rock) - A rock formed by the process of emplacement of magma (liquid rock) in pre-existing rock. (e.g. granite, granodiorite, quartz monzonite).

LACUSTRINE DEPOSITS - Materials deposited in lake environment.

LINE - A linear array of observation points, such as a seismic line.

LIQUID LIMIT - See ATTERBERG LIMITS.

LOESS - A wind blown deposit predominantly silt or silty clay or clayey silt.

LOW ENERGY FLOW - See FLOODING.

MAGNETIC INTENSITY - A vector quantity measuring magnetic field strength. The unit of magnetic intensity commonly used in geophysical exploration is the gamma (see GAMMA).

MANTLED PLAYA - A playa surface or a portion of the surface that is covered with younger geologic material such as windblown sand, or alluvium.

MILLIGAL - A unit of acceleration used with gravity measurements; 1 milligal = 10^{-5} m/sec.². Abbreviated mgal.

GLOSSARY OF TERMS (Cont.)

MOISTURE CONTENT - The ratio, expressed as a percentage, of the weight of water contained in a soil sample to the oven-dry weight of the sample.

N VALUE - Penetration resistance, number of blows required to drive the standard split spoon sampler for the second and third six inches (0.15 m) with a 140 pound (63.5 kg) hammer falling 30 inches (0.76 m) (ASTM D1586-67).

OPTIMUM MOISTURE CONTENT - Moisture content at which a soil can be compacted to a maximum dry unit weight by a given compactive effort

OVERBANK FLOODING - A large flow of water that overflows the sides of A stream channel.

O - Angle of internal friction

PATINA - A dark coating or thin outer layer produced on the surface of a rock or other material by weathering after long exposure (e.g., desert varnish).

PAVEMENT/DESERT PAVEMENT - When loose material containing pebble-sized or larger rocks is exposed to rainfall and wind action the finer dust and sand are blown or washed away and the pebbles gradually accumulate on the surface, forming a mosaic which protects the underlying finer material from wind attack. Pavement can also develop in finer-grained materials. In this case the armored surface is formed by dissolution and cementation of the grains involved.

PEGMATITE DIKE - A coarse grained igneous rock of granitic composition that forms as a tabular intrusion that cuts across the planar structures of the surrounding rock.

P-WAVE - See COMPRESSIONAL WAVE.

PERIMETER SEISMIC REFRACTION SURVEY - Shallow seismic refraction measurements made around the perimeter of a valley.

PERMEABLE - The ability of liquid to pass through soil and/or rock material.

PICK-UP - See GEOPHONE.

GLOSSARY OF TERMS (Cont.)

- PITCHER TUBE SAMPLE - An undisturbed, 2.87 inch (73 mm) diameter soil sample obtained from a drill hole with a Pitcher tube sampler. The primary components of this sampler are an outer rotating core barrel with a bit and an inner stationary, spring-loaded, thin-wall sampling tube which leads or trails the outer barrel drilling bit, depending upon the hardness of the material being penetrated.
- PLASTIC LIMIT - See ATTERBERG LIMITS.
- PLASTICITY INDEX - See ATTERBERG LIMITS.
- PLAYA/PLAYA DEPOSITS - A term used in the southwest U.S. for a dried-up, flat-floored area composed of thin, evenly stratified sheets of fine clay, silt, or sand, and representing the lowest part of a shallow, completely closed or undrained, desert lake basin in which water accumulates and is quickly evaporated, usually leaving deposits of soluble salts.
- PONDING (of water) - The accumulating of water in a topographic depression.
- PRIME - Modifier used to indicate the highest ranking province, region, area, or site. If not an interdisciplinary ranking, then a qualifier should be used such as "prime" geotechnical candidate siting area".
- PROXIMAL - That portion of an alluvial deposit nearest to its point of origin.
- REGIONAL - The general attitude or configuration disregarding features smaller than a given size. The regional gravity is the gravity field produced by large-scale variations ignoring anomalies of smaller size. See residualize.
- RELATIVE AGE - The relationship in age (oldest to youngest) between geologic units without specific regard to number of years.
- RESIDUAL - What is left after a regional field has been removed, as in gravity or magnetic analysis. See RESIDUALIZE.

GLOSSARY OF TERMS (Cont.)

RESIDUALIZE - The process of separating a graphically depicted curve or a surface into its low-frequency parts (called the regional) and its high-frequency parts (called the residual). Residualizing is an attempt to sort out of the total field those anomalies which result from local structure; that is, to fine local anomalies by subtracting gross (regional) effects.

ROCK UNITS - Distinct rock masses with different characteristics (e.g., igneous, metamorphic, sedimentary).

S-WAVE - See SHEAR WAVE.

SAND - Soil passing through No. 4 (4.75 mm) sieve and retained on No. 200 (0.075 mm) sieve

SAND DUNE - A low ridge or hill consisting of loose sand deposited by the wind, found in various desert and coastal regions and generally where there is abundant surface sand.

SEISMIC - Having to do with elastic waves. Energy may be transmitted through the body of an elastic solid as P-waves (compressional waves) or S-waves (shear waves).

SEISMIC REFRACTION DATA: deep/shallow - Data derived from a type of seismic shooting based on the measurement of seismic energy as a function of time after the shot and of distance from the shot, by determining the arrival times of seismic waves which have travelled nearly parallel to the bedding in high-velocity layers, in order to map the depth to such layers.

SEISMOGRAM - A seismic record.

SEISMOMETER - See GEOPHONE.

SHEAR WAVE - A body wave in which the particle motion is perpendicular to the direction of propagation. Also called S-Wave or transverse wave.

SHEET FLOW - A process in which storm-borne water spreads as a thin, continuous veneer (sheet) over a large area.

SHEET SAND - A blanket deposit of sand which accumulates in shallow depressions or against rock outcrops, but does not have characteristic dune form.

SHOT - Any source of seismic energy; e.g., the detonation of an explosive.

GLOSSARY OF TERMS (Cont.)

- SHOT POINT - The location of any source of seismic energy; e.g., the location where an explosive charge is detonated in one hole or in a pattern of holes to generate seismic energy. Abbreviated SP.
- SILT AND CLAY - Fine-grained soil passing through No. 200 (0.075 mm) sieve.
- SITE - Location of some specific activity or reference point. The term should always be modified to a precise meaning or be clearly understood from the context of the discussion.
- SPECIFIC GRAVITY - The ratio of the weight in air of a given volume of soil solids at a stated temperature to the weight in air of an equal volume of distilled water at a stated temperature.
- SPLIT SPOON SAMPLE - A disturbed sample obtained with a split spoon sampler with an outside diameter of 2.0 inches (5.1 cm). The sample consists of a split barrel which is driven into the soil using a drop-hammer.
- SPREAD - The layout of geophone groups from which data from a single shot are recorded simultaneously. Spreads containing twenty-four geophones have been used in Fugro's seismic refraction surveys.
- STREAM CHANNEL DEPOSITS - Materials (clay, silt, sand, gravel, cobbles, boulders) which have been deposited in a stream channel.
- STREAM TERRACE DEPOSITS - Stream channel deposits no longer part of an active stream system, generally loose, moderately well graded sand and gravel.
- SURFICIAL DEPOSIT - Unconsolidated residual and alluvial deposits occurring on or near the earth's surface.
- TRANSITORY - A poorly defined, shallow ephemeral stream across an alluvial fan surface, the position of which is temporary and tends to shift frequently.
- UNCONFINED COMPRESSION - A type of test to measure the compressive strength of an undisturbed soil sample.
- UNIFIED SOIL CLASSIFICATION SYSTEM (USCS) - A system which determines soil classification on the basis of grain-size distribution and Atterberg Limits. (See page A-17).

GLOSSARY OF TERMS (Cont.)

VALLEY SEISMIC REFRACTION SURVEY - Deep seismic refraction measurements made near the middle of a valley to determine seismic wave propagation velocities and thickness of basin fill.

VELOCITY - Refers to the propagation rate of a seismic wave without implying any direction. Velocity is a property of the medium and not a vector quantity when used in this sense.

VELOCITY LAYER - A layer of rock or soil with a homogenous seismic velocity.

VELOCITY PROFILE - A cross-section showing the distribution of material seismic velocities as a function of depth and its configuration.

WASH SAMPLE - A sample obtained by screening the returned drilling fluid during rotary wash drilling to obtain lithologic information between samples.

Definitions were derived in part from Webster's New Collegiate Dictionary (1972 edition), Glossary of Geology (American Geological Institute, 1972), Encyclopedic Dictionary of Exploration Geophysics (Sheriff, 1973), and 1976 Annual Book of ASTM Standards.

DIAGNOSTIC CARBONATE MORPHOLOGY

STAGE	GRAVELLY SOILS	NONGRAVELLY SOILS
I	Thin, discontinuous pebble coatings	Few filaments or faint coatings
II	Continuous pebble coatings, some interpebble fillings	Few to abundant nodules, flakes, filaments
III	Many interpebble fillings	Many nodules and internodular fillings
IV	Laminar horizon overlying plugged horizon	Laminar horizon overlying plugged horizon

Stages of development of a caliche profile with time. Stage I represents incipient carbonate accumulation, followed by continuous build-up of carbonate until, in Stage IV, the soil is completely plugged.

SUMMARY OF CALICHE DEVELOPMENT

GEOLOGIC
UNIT

Au, Ast	Au	Non-rock Deposits (undifferentiated); fine- to coarse-grained materials deposited by alluvial, fluvial, eolian, lacustrine, gravity or glacial processes.	
Aal	A1	Fluvial Deposits; predominantly composed of poorly- to well-graded sand and gravel with lesser amounts of silt- and boulder-sized material. The unit predominantly consists of recent water-laid deposits occupying present drainages and flood plains. - Older Fluvial Deposits (A1o) are generally thicker, more extensive units deposited in ancestral fluvial systems. - Alluvial Outwash Deposits (A1w) consist of mixed, geomorphically nondescript alluvial and fluvial deposits covering large, relatively flat, river and playa basins.	gr Vu Vb
At	A2	Terrace Deposits; predominantly composed of moderately to well graded, clay- to gravel-sized material. Principally elevated terraces bordering modern streams (A2s) and lakes playas (A2l).	Su
	A3	Eolian Deposits; predominantly composed of poorly graded sand-sized material deposited by wind action. Deposits may consist of mixed sand, silt, and clay (A3u), or be differentiated on the basis of predominant grain size and landform. A3s d - Predominantly fine sand-sized material deposited in sheets (A3s) or dunes (A3d). A3l - Loess composed predominantly of silt-sized material with lesser amounts of clay and fine sand. A3f - Predominantly clay-sized material with lesser amounts of silt and fine sand.	Qtz Psa, Pn, Ph, Cau, Ls, Py, Par
	A4	Lacustrine, Estuarine, and Playa Deposits; predominantly composed of poorly graded clay, silt, and fine sand deposited in bodies of standing water. Older lacustrine, estuarine, and playa deposits (A4o) are thicker, more extensive units occupying ancestral lake basins	Qtz, gn
Aaf	A5	Alluvial Fan Deposits; predominantly composed of well graded sand and gravel with varying amounts of silt-, cobble-, and boulder-sized material. Deposited principally by distributary channels adjacent to mountain fronts. Relative ages are indicated by o - older, i - intermediate, or y - younger	
	A6	Pediment, Pediment Deposits, and Areas of Shallow Rock; planated bedrock shelf or near surface rock generally overlain by a thin mantle of sand- to boulder-sized residual or alluvial material.	
	A7	Colluvial Deposits; predominantly composed of moderately- to well-graded sand and gravel with varying amounts of silt-, cobble-, and boulder-sized material. Deposited locally by gravity and water adjacent to steep gradients.	

NOTES: (1) AREI symbols were developed for use in the Aggregate Resources Evaluation Investigation (See Section 5.1 and Drawings 5.1A through 5.1C)

(2) MX Geologic units were used for Methodology, Screening, and Characterization studies.

MX (2)
GEOLOGIC
UNITS

ROCK UNITS

Shown in regions where rock is exposed; the areally predominant (greater than 70 percent) rock type is indicated. In those areas where two rock types occur the predominant rock type is shown followed by the subordinate rock type (e.g. S2MP I4T).

I IGNEOUS (UNDIFFERENTIATED). Rocks formed by solidification of a molten or partially molten mass.

- gr I1 Intrusive - Typically crystalline, formed by the solidification of molten material below the surface (e.g., granite, syenite, diorite).
- Vu I2 Extrusive (undifferentiated). Formed by solidification of molten material at or near the surface.
- Vb I3 Extrusive (flows). Extrusive rocks formed by solidification of lava (e.g. basalt, dacite) I3b denotes young basaltic flows which may be interbedded with basin-fill materials.
- I4 Extrusive (volcaniclastic). Formed by accumulation, welding and or cementation of deposits of volcanic ejecta (e.g. tuff, agglomerate, lapilli).

Su **S SEDIMENTARY (UNDIFFERENTIATED).** Coarse- to fine-grained materials that exhibit some degree of cementation and were deposited by water, wind, gravity, or evaporation.

- Qtz
Psa, Pn,
Ph, CaO,
Ls, Py,
Par
- S1 Sandstone. Composed predominantly of sand-sized particles.
- S2 Limestone and Dolomite. Composed predominantly of carbonate material.
- S3 Shale. Composed predominantly of clay- and silt-sized particles (e.g. shale, siltstone, mudstone).
- S4 Evaporites. Sediments deposited from solution as a result of evaporation (e.g. gypsum, anhydrite, halite).
- S5 Clastics. Undifferentiated deposits composed of silt- to boulder-sized material. May be angular to rounded.

Qtz, gn **M METAMORPHIC (UNDIFFERENTIATED).** Rocks formed through alteration of igneous or sedimentary rock material by pressure, heat, or chemical changes below the weathered zone (e.g. gneiss, schist, slate, marble, quartzite).

C ROCK COMPLEXES. Indicated where no areally predominant (greater than 70 percent) rock type is present.

USAGE

Modifying letter (r) indicates concentrations of resistant secondary carbonate (caliche), silicious, ferruginous and or gypsiferous material, e.g. A5rr.

A3s A5v - Mixed non-rock units; most areally extensive unit is listed first.

A5v(A3r) - Parenthetic unit underlies thin veneer of overlying mapped unit.

S5to - Established formations may have a supplemental letter added to distinguish formal designation (e.g. Tertiary Ogallala Fm.)

TABLE
A-1

FUGRO NATIONAL, INC.

Major Divisions			Group Symbols	Typical Names	Field Identification Procedures (Excluding particles larger than 3 inches and having fractions on estimated weights)	Information Required for Describing Soils	
1	2	3	4	5	6		
Coarse-grained Soils More than half of material is larger than No. 200 sieve size. The No. 200 sieve size is about the smallest particle visible to the naked eye.	Gravels More than half of coarse fraction is larger than No. 4 sieve size. (For visual classification, the No. 4 sieve size may be used as Gravel fraction is larger than No. 4 sieve size.)	Sands More than half of coarse fraction is smaller than No. 4 sieve size. (For visual classification, the No. 4 sieve size may be used as Sand fraction is smaller than No. 4 sieve size.)	Clean Gravels (Little or no fines)	GW	Well-graded gravels, gravel-sand mixtures, little or no fines.	Wide range in grain sizes and substantial amounts of all intermediate particle sizes.	For undisturbed soils add information on stratification, degree of compactness, cementation, moisture conditions and drainage characteristics. Give typical name; indicate approximate percentages of sand and gravel, max. size; angularity, surface condition, and hardness of the coarse grains; local or geologic name and other pertinent descriptive information; and symbol in parentheses. Example: Silty sand, gravelly; about 20% hard, angular gravel particles 1/4-in. maximum size; rounded and sub-angular sand grains coarse to fine; about 15% nonplastic fines with low dry strength; well compacted and moist in place; alluvial sand; (SM).
			Clean Sands (Little or no fines)	GP	Poorly-graded gravels, gravel-sand mixtures, little or no fines.	Predominantly one size or a range of sizes with some intermediate sizes missing.	
			Gravels with Fines (Appreciable amount of fines)	GM	Silty gravels, gravel-sand-silt mixtures.	Nonplastic fines or fines with low plasticity. (for identification procedures see ML below)	
			Clean Sands (Little or no fines)	GC	Clayey gravels, gravel-sand-clay mixtures.	Plastic fines (for identification procedures see CL below)	
			Clean Sands (Little or no fines)	SW	Well-graded sands, gravelly sands, little or no fines.	Wide range in grain sizes and substantial amounts of all intermediate particle sizes.	
			Clean Sands (Little or no fines)	SP	Poorly-graded sands, gravelly sands, little or no fines.	Predominantly one size or a range of sizes with some intermediate sizes missing.	
			Sands with Fines (Appreciable amount of fines)	SM	Silty sands, sand-silt mixtures.	Nonplastic fines or fines with low plasticity. (for identification procedures see ML below)	
			Sands with Fines (Appreciable amount of fines)	SC	Clayey sands, sand-clay mixtures.	Plastic fines (for identification procedures see CL below)	
			Silty and Clays Liquid limit greater than 50	Identification Procedures on Fraction Smaller than No. 40 Sieve Size			
	Dilatancy (Reaction to shaking)	Dry Strength (Crushing characteristics)		Toughness (Consistency near PL)			
	ML	Inorganic silts and very fine sands, rock flour, silty or clayey fine sands or clayey silts with slight plasticity.		None to slight	Quick to slow	None	
	CL	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays.		Medium to high	None to very slow	Medium	
	OL	Organic silts and organic silty clays of low plasticity.		Slight to medium	Slow	Slight	
	MI	Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts.		Slight to medium	Slow to none	Slight to medium	
	Highly Organic Soils	CH	Inorganic clays of high plasticity, fat clays.	High to very high	None	High	
OH		Organic clays of medium to high plasticity, organic silts.	Medium to high	None to very slow	Slight to medium		
Pt		Peat and other highly organic soils.	Readily identified by color, odor, spongy feel and frequently by fibrous texture.

SAMPLE TYPES

-  STANDARD PENETRATION TEST
-  FUGRO DRIVE
-  BULK
-  PITCHER TUBE

ENGINEERING PARAMETERS

- N — STANDARD PENETRATION TEST (ASTM: D-1586-87)
- R — N VALUE GREATER THAN 100 BLOWS/FOOT
- ▲ — DRY UNIT WEIGHT (ASTM: D-2937-71)
- — MOISTURE CONTENT (ASTM: D-2216-71)
- NR — NO RECOVERY

BORING DETAILS

ELEVATION : 2520' (768m)
 DATE DRILLED : 24 January 1978
 DRILLING METHOD : Hollow Stem Auger
 HOLE DIAMETER : 6 5/8" (168mm)
 CASING INSTALLED: None
 WATER LEVEL : Not Encountered
