FOREWORD

This report is one of a series prepared for the Department of the Air Force, Ballistic Missile Office (BMO), in compliance with Contract No. F04704-80-C-0006, CDRL Item No. 004A2. These reports present the results of Detailed Aggregate Resources Studies within and adjacent to selected areas in Nevada and Utah that are under consideration for siting the MX missile system.

This volume contains the results of the aggregate resources evaluation for Delamar Valley. Results of this report are presented as text, appendices, and three drawings. This report has been prepared and submitted on the assumption that the reader is familiar with previous aggregate resources reports.

EXECUTIVE SUMMARY

This report contains the Detailed Aggregate Resources Study (DARS) evaluation for Delamar Valley, Nevada. It is the first in a series of reports that contain detailed aggregate information on the location and quality of basin-fill and rock sources of road-base and concrete aggregates. Field reconnaissance, laboratory testing, and existing data from other Ertec Western, Inc. (formerly Fugro National, Inc.) investigations and the Nevada Department of Highways provide the basis for the findings presented in this report.

ROAD-BASE AGGREGATES

Potential road-base aggregate sources were classified as follows:

- Class RB1a - Basin-fill or rock sources containing materials suitable for use as road-base aggregates; based on acceptable laboratory aggregate test results.
- Class RB1b - Basin-fill sources containing materials suitable for use as road-base aggregates; based on correlation with Class RB1a source areas.
- Class RBII - Potential basin-fill sources of materials suitable for use as road-base aggregates; based on photogeologic interpretations, field observations, and limited or inconclusive sieve analysis and/or abrasion data.

Assignment of an aggregate source to one of the above three classes was determined from laboratory test results (gradation, abrasion and, to a lesser extent, soundness) and geomorphological and compositional correlations.

Results of this evaluation are presented on a 1:62,500 scale aggregate resources map (Drawing 2) and are summarized as follows:

Class RB Ia Sources: Seven basin-fill sources consisting of good to high quality aggregates acceptable for use as road-base construction materials have been located on the east side of the valley. The deposits are all alluvial fans (Aaf).

Class RB Ib Sources: Seven basin-fill deposits within the study area are defined as potential sources of good to high quality, road-base aggregates. Geomorphological and compositional similarities were used to correlate these units to tested RB Ia deposits. Six of the deposits are alluvial fans (Aaf) and one is a stream-channel deposit (Aal). All are confined to the east side of the valley.

Class RB II Sources: Several potential basin-fill aggregate sources are located throughout the study area. All of these sources are alluvial fans that have been classified on the basis of limited field and laboratory data.

CONCRETE AGGREGATES

A classification system consisting of five classes was developed for the concrete aggregates evaluation to present potential basin-fill and crushed-rock sources. Although most rock sources will supply coarse concrete aggregates, their delineation was not an objective of this study. Assignment of an aggregate source to one of the five classes was determined from laboratory test results (trial concrete mixes and gradation, abrasion, and soundness of aggregates) and geomorphological and compositional correlations. The emphasis of this study was the evaluation of

the concrete-making properties (especially 28-day compressive strengths) of potential aggregates when used in trial concrete mixes.

- Class CA1 Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths equal to or greater than 6500 psi.
- Class CA2 Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths less than 6500 psi.
- Class CB Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on acceptable laboratory aggregate test results.
- Class CC1 Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on correlation with Class CA1 and CA2 source areas.
- Class CC2 Basin-fill sources containing aggregates potentially suitable for use in concrete; based on correlation with Class CB source areas.

The following three trial mixes were used to obtain a range of compressive strength values; however, only Mix 3 results were used to classify sources. In all three trial mixes, fly ash, as a pozzolan, replaced 20 percent of the cement by weight.

- o Mix 1 - 7.5 sacks of cement per cubic yard of concrete and 1.5-inches maximum aggregate size;
- o Mix 2 - 8.5 sacks of cement per cubic yard of concrete and 1.5-inches maximum aggregate size; and
- o Mix 3 - 8.5 sacks of cement per cubic yard of concrete, 0.75-inch maximum aggregate size, and a superplasticizer.

Results of this evaluation are presented on a 1:62,500 scale aggregate resources map (Drawing 3) and summarized as follows:

Class CA1 Sources: One basin-fill deposit in the area contained aggregates that, when used in Mix 3, produced 28-day compressive strengths greater than 6500 psi. The source is an alluvial fan (Aaf) and is located on the east side of the valley.

Class CB Sources: Five basin-fill deposits consisting of good to high quality aggregates, potentially acceptable for use as concrete construction materials, were delineated on the east side of the valley. All of these deposits are alluvial fans.

Class CC1 Sources: One alluvial fan in the study area is classified as a potential source of concrete aggregates. It is correlated to the Class CA1 source on geomorphological and compositional similarities.

Class CC2 Sources: Alluvial units located along the eastern side of the valley are potential sources of aggregates suitable for use in concrete. They are correlated to Class CB units on the basis of geomorphological and compositional similarities.

CONCLUSIONS

Sufficient quantities of coarse and fine aggregates suitable for use as road-base and/or concrete construction material are available in Delamar Valley. Laboratory test results indicate that the quality of the coarse aggregates ranges from good to excellent, and the quality of the fine aggregates ranges from poor to satisfactory. Most of the aggregate sources are confined to the east side of the valley.

RECOMMENDATIONS

Additional aggregate field investigations and laboratory testing will be required to further refine the physical and chemical characteristics of road-base and concrete aggregate sources as borrow areas prior to the initiation of construction.

1.0 INTRODUCTION

1.1 STUDY AREA

This report presents the results of the Detailed Aggregate Resource Study (DARS) for Delamar Valley (Figure 1). Delamar Valley is located in south-central Lincoln County, Nevada. The valley is bounded on the west by the South Pahroc Range, on the east and south by the Delamar Mountains, and on the northeast by the southern extent of the Burnt Springs Range. U.S. Highway 93 is the northern boundary of the study area and the only paved road in the vicinity. A network of graded roads and four-wheel-drive trails provide access to most of the study area. Delamar Valley is mainly undeveloped desert rangeland administered by the Bureau of Land Management (BLM). Several active and inactive mining operations are located in the Delamar Mountains. The nearest town is Caliente, Nevada, located approximately 15 miles (24 km) east of Delamar Valley on U.S. Highway 93.

1.2 BACKGROUND

Aggregate resources studies for the MX program were introduced in 1977 with the investigation of Department of Defense (DoD) and BLM lands in California, Nevada, Arizona, New Mexico, and Texas (FN-TR-20D). Refinement of the MX siting area added portions of Utah and Nevada that were not evaluated in this initial Aggregate Resources Evaluation Investigation (AREI). This additional area, defined as the Utah-Nevada aggregate resources study area, was examined in the fall of 1979, and a second general aggregate resources report was submitted on 3 March 1980 (Figure 2).

DETAILED AGGREGATE RESOURCES STUDY DELAMAR VALLEY, NEVADA

29 MAY 81

FIGURE 1

Both regional aggregate investigations consisted of the compilation and evaluation of existing data with limited field reconnaissance, sample collection, and laboratory aggregate testing. Only general information on the location, quality, and quantity of aggregates was provided.

Subsequent to the regional studies, Valley-Specific Aggregate Resources Studies (VSARS) were developed in FY 79. The primary objective of these continuing studies is to provide additional information on potential aggregate sources in specified valleys and in the immediate surrounding areas. Existing exposures of potential basin-fill and rock aggregate sources are sampled and subjected to a suite of laboratory aggregate tests. Results of these tests are used to classify coarse and fine basin-fill and crushed-rock aggregates for suitability as concrete and road-base construction materials.

The aggregate sources presented in VSARS are to be used as a guide for preliminary construction planning and the selection of areas for more detailed-aggregate evaluations. To date, field investigations have been completed for 16 valley areas with final reports submitted for 11 (Figure 3). Field investigations for remaining valleys in the designated deployment area are planned in FY 81 and FY 82.

The DARS were initiated in FY 81 to further analyze and refine potential sources of coarse and fine basin-fill and crushed-rock aggregates identified during the VSARS. These studies consist of both road-base (Section 3.0) and concrete (Section 4.0)

aggregate evaluations. The major consideration was to further evaluate basin-fill deposits as potential sources of road-base and concrete aggregates. Limited new data were developed on crushed-rock sources.

1.3 OBJECTIVES

The objectives of the Detailed Aggregate Resources Study are as follows:

Road-Base Aggregates Evaluation

- o Refine potential basin-fill and rock sources (initially identified in VSARS) for road-base aggregates; and
- o Provide additional laboratory test data on the general quality of basin-fill aggregates for use as road-base material.

Concrete Aggregates Evaluation

- o Refine the areal extent of the most acceptable VSARS basin-fill and rock, concrete aggregate sources; and
- o Provide additional laboratory testing information on the quality and the concrete-making properties of potential coarse and fine basin-fill and crushed-rock aggregates.

1.4 SCOPE

The scope of the two evaluations required office and field studies and included the following:

- a. Compilation and analysis of appropriate existing data on the quality and quantity of potential road-base and concrete aggregates. Major sources of data were other Ertec investigations for the siting of the MX system and the Nevada Department of Highways.
- b. Initial and final basin-fill deposit differentiation based on geomorphology, grain-size, lithology, and aerial photography and topographic map interpretation. Initial and final rock unit divisions based on evaluations of aerial photography and published geologic maps.
- c. Staking and permitting on selected BLM lands. Appropriate basin-fill trench locations for samples of road-base and concrete aggregates were determined from items a and b and a brief field reconnaissance.

- d. Backhoe excavation of staked and permitted basin-fill locations, sampling when gravel percentage exceeded 30 percent, or when suitable fine aggregates for concrete mixes were present. Selection and sampling of acceptable crushed-rock sources of coarse aggregates for concrete mixes.
- e. Valley-wide field reconnaissance utilizing aerial photography and petrographic and grain-size analyses to determine lateral extent and acceptability of basin-fill deposits.
- f. Laboratory tests to supplement available existing data for the determination of the suitability of specific basin-fill and rock units as sources of road-base or concrete aggregates. Trial (check) concrete mixes were made to evaluate the basic concrete-making properties of selected concrete aggregate sources as well as engineering properties of hardened concrete.
- g. Development and application of road-base and concrete materials classification systems that textually and graphically depict the locations of the most suitable aggregate sources in the study area. The depiction and discussion of areas that are unsuitable or have a low probability for use were not done.

2.0 GEOLOGICAL SETTING

2.1 PHYSIOGRAPHY

Delamar Valley lies within the Basin and Range Physiographic Province. The primary physiographic features of the study area are uplifted mountains and a down-dropped, intervening alluvium-filled basin. These north-south trending features are controlled by block-faulting and are typical of the Basin and Range Province. Elevations range from about 5600 feet (1707 m) in the east-central part of the valley to about 4540 feet (1384 m) on the playa in the southern part of the valley.

Mountain ranges flanking the basin are the South Pahroc Range on the west, Burnt Springs Range on the northeast, and the Delamar Mountains on the east and south. Delamar Valley is open to Dry Lake Valley to the north. Topographic relief between mountain ridges and the basin ranges from about 975 feet (297 m) to about 2400 feet (732 m) along the western side of the study area and from approximately 1400 to 1800 feet (427 to 549 m) along the eastern side of the study area. Delamar Valley is a closed-drainage system with a large playa in the southern portion of the study area.

2.2 LOCATION AND DESCRIPTION OF GEOLOGICAL UNITS

Paleozoic, Mesozoic, and Cenozoic rocks are found in bedrock outliers within the valley fill and in the mountains within and adjacent to the study area. The Paleozoic rocks consist predominantly of limestone, dolomite, and quartzite with interbedded sandstone and shale. These units crop out across the

entire eastern study area margin and, where not exposed, underlie younger geologic units. Unconformably overlying the Paleozoic rocks are Mesozoic rocks consisting predominantly of undifferentiated volcanic and intravolcanic sedimentary rocks. Cenozoic rocks unconformably overlie Paleozoic and Mesozoic units and consist of Tertiary intrusives and volcanics. Unconsolidated Cenozoic deposits lie unconformably above all older units and consist primarily of alluvial, lacustrine, and stream-channel and terrace deposits.

Additional geologic information is presented in previous Ertec reports (FN-TR-27-DM-I and II; FN-TR-37-a).

2.2.1 Rock Units

Geologic rock units, previously classified as potential sources of crushed-rock aggregates during the VSARS program, are unclassified in this report. No specific rocks from the study area were sampled or tested during the DARS program. Rocks classified during the more general VSARS program as good sources were extrapolated from test results in adjoining valleys. These results could not be confidently correlated into the study area for the more selective DARS evaluation.

2.2.2 Basin-Fill Units

The basin-fill geologic units within the study area that are potential sources of coarse and fine aggregates are alluvial fan deposits (Aaf) and stream-channel and terrace deposits (Aal). The grouping of the units was based on similarities in physical and chemical characteristics and map-scale limitations. All

other basin-fill units may locally supply aggregates but are not considered major sources and will not be discussed in this report.

2.2.2.1 Alluvial Fan Deposits - Aaf

Alluvial fan deposits (Aaf) are the most extensive potential sources of basin-fill aggregates within the study area. They occur in a fairly narrow band along most of the east side of the valley and in scattered locations on the west side of the valley. Alluvial fan deposits are typically heterogeneous to poorly stratified mixtures of boulders, cobbles, gravel, sand, silt, and clay. Large quantities of boulder- and cobble-sized material exist along the east side of the valley adjacent to the mountain fronts. On the east side of the valley, alluvial fan deposits consist predominantly of sandy gravel. Alluvial fan deposits on the west side are predominantly gravelly sand.

Most alluvial fan deposits have developed soil horizons consisting of silty, clayey sand that are a few inches (centimeters) to 1 foot (0.3 m) in thickness overlying a zone of carbonate accumulation (caliche). The caliche horizon generally ranges in thickness from 1 to 2 feet (0.3 to 0.6 m) and exhibits Stage I to III development with Stage II and III being most common (Appendix F).

2.2.2.2 Stream-Channel and Terrace Deposits - Aal

Stream-channel and terrace deposits (Aal) in the study area are associated with ephemeral streams within the valley. They range

in composition from sandy gravel and gravelly sand near the mountain fronts to sandy silts near the valley axis. Caliche development within the stream-channel deposits ranges from absent to minor Stage I, occurring as thin lenses and layers or as coatings on the underside of coarse-grained clastic material. One stream-channel deposit has been delineated in the study area on the northeast side of the valley near U.S. Highway 93. No major terrace deposits were mapped in the study area.

3.0 ROAD-BASE AGGREGATES EVALUATION

3.1 STUDY APPROACH

The primary objective of the road-base aggregates study was to evaluate the suitability of basin-fill and rock aggregates for use as road base. Two important considerations were applied to basin-fill aggregate sources identified as potentially suitable in VSARS; refinement of source boundaries and additional laboratory tests to further evaluate physical and chemical characteristics. Sources of crushed-rock aggregates were refined using only existing data, published geologic maps, and limited photogeologic interpretations. Information on potential rock sources for use as road-base aggregates was not specifically collected for this evaluation. Only existing VSARS data and data developed from the concrete aggregates evaluation (Section 4.0) were assessed.

The study approach for the road-base aggregates evaluation required a review of previous Ertec Verification (FN-TR-27-DM-I and II) and aggregate reports (FN-TR-20D and FN-TR-37-a) for Delamar Valley. This data base helped define the scope of the road-base materials investigation which included office and field photogeologic and topographic interpretations, field reconnaissance, and collection and laboratory testing of basin-fill samples.

3.1.1 Requirements for Road-Base Aggregates

For the purpose of this report, road-base aggregates are defined using the Nevada Department of Highways (1976) classification of

Type I Class A aggregate base. The requirements for aggregates suitable for such a base are as follows:

Gradation:

<u>Sieve Size</u>	<u>Percent Passing by Weight</u>
1.5 inches	100
1.0 inch	80-100
No. 4	30- 65
No. 16	15- 40
No. 200	2- 12
Fractured Faces	35 percent, minimum
Plasticity Index	3-15 percent
Liquid Limit	35 maximum
Resistance (R value)	70 minimum
Percent Wear (500 Rev.)	45 percent, maximum

During the road-base aggregate studies, gradation and percent wear were the two primary criteria used to evaluate potential source areas. Magnesium sulfate ($MgSO_4$) soundness tests were performed on selected aggregate samples to gain additional information related to the effects of weathering on aggregates. Soundness losses exceeding 18 percent were considered potentially unacceptable (American Society of Testing and Materials, 1978). The remaining requirements were not evaluated during this study.

3.1.2 Data Acquisition and Analysis

Office studies for the road-base aggregates evaluation required preliminary basin-fill and rock-unit differentiation based on photogeologic interpretations and published topographic and geologic maps. All available data on basin-fill grain-size gradations were compiled to estimate gravel content for the defined basin-fill units.

The field program involved backhoe excavation of 31 trenches selected during office studies and initial field reconnaissance. Trenches were excavated and sampled in groups of three, 0.1 to 0.2 mile (0.2 to 0.3 km) apart, to characterize individual basin-fill units. Completion depths ranged from 12 to 15 feet (3.7 to 4.6 m) and, where collected, representative samples averaged 100 pounds (45 kg) per trench.

Due to gradation variability in basin-fill deposits, field limits of 30 percent or more gravel and 20 percent or less silt and clay were established as basic aggregate grain-size distribution requirements. Gravel is defined as coarse aggregates which pass the 3.0-inch (75-mm) sieve and are predominantly retained on a No. 4 (4.75-mm) sieve. Aggregates larger than 3.0 inches (cobbles and boulders) were generally present in the materials investigated but were not included in the laboratory samples because of sample-size limitations. Silt and clay particles are defined as material passing through a No. 200 sieve (0.0029-inch [0.075-mm]).

Field studies also included 37 petrographic and grain-size data field stops and valley-wide photogeologic field reconnaissance. These analyses were performed to supplement and confirm office studies and to provide a data base for lithologic and gradation correlations of basin-fill units.

Laboratory testing that included 28 sieve analyses, six abrasion tests, and four MgSO_4 soundness tests was performed to broaden

the existing data base during the road-base aggregates evaluation. Confirmation test data (gradation, abrasion, and soundness tests) from the concrete aggregates evaluation (Section 4.0) were also used to supplement test data for the road-base aggregates evaluation.

The scope of the study did not allow sample collection and laboratory testing of all potential road-base aggregate sources. Existing data and field petrographic and grain-size analyses were used to correlate lithologic and gradation properties to basin-fill units which were not sampled. An important element of this correlation procedure was the use of aerial photography to help delineate the lateral extent of basin-fill deposits. Photogeologic and field observations ascertained geomorphological and topographical relationships of basin-fill units and the source rock lithology and distribution of predominantly gravelly materials.

3.1.3 Presentation of Results

Results of the road-base aggregates evaluation are presented in the form of text, figures, 1:62,500 scale drawings, and appendices. Drawing 1 shows the locations of all the data points used in the Detailed Aggregate Resources Study. The data points are grouped by study type and assigned categorized map numbers. VSARS data points are designated by map numbers 1 to 199 and correspond to map numbers in the appendix table of the Delamar area VSARS report (FN-TR-37-a). DARS data points are assigned map number groups 200 to 299 for trench locations and 300 to 399

for petrographic and grain-size data stop locations. Verification data points are assigned the map number group 400 to 599. Appendix Table G-1 converts map number to Delamar Verification Report (FN-TR-27-DM-I and II) activity type and number for direct reference.

Drawing 2 presents the locations of all potential road-base aggregate sources, DARS trenches, and field petrographic and grain-size data stops in the study area. Geologic unit symbols used in Drawing 2 relate to standard geologic nomenclature whenever possible. A conversion table relating these symbols to the geologic unit nomenclature used in other Ertec reports is contained in Appendix Table F-3.

A solid contact line separates basin-fill and rock units in Drawing 2 to differentiate these two basic material types. Basin-fill contacts are derived from photogeological mapping with limited field reconnaissance and are dashed.

Classifications of potential sources of basin-fill road-base aggregates are distinguished by different patterns and are emphasized by a dark background tone.

The appendices contain tables that summarize the basic field data collected during the course of the study and the subsequent laboratory test procedures and results. Appendices A and B include DARS trench data and petrographic and grain-size analysis data, respectively. Appendix C contains representative trench logs. Appendix Table D-1 presents a laboratory testing flow

diagram for the road-base aggregates evaluation. Appendix F includes three tables describing soil classification, caliche development, and geologic unit cross reference.

3.1.4 Classification of Road-Base Aggregates

A classification system was designed to present the most likely potential sources of basin-fill and crushed-rock road-base aggregates. It was developed from an evaluation as well as from an extrapolation of all available data.

This classification system is primarily based on laboratory test results (gradation and abrasion and, to a lesser extent, soundness) and geomorphological and compositional correlations. The classification is presented in hierarchy form; classification of the highest potential source areas is described first and classification of the lowest potential source areas is described last.

<u>Class</u>	<u>Explanation</u>
RB1a	Basin-fill or rock sources containing materials suitable for use as road-base aggregates; based on acceptable laboratory aggregate test results.

Class RB1a includes those source areas where the potential for suitable road-base aggregates is the highest. Each delineated area has been sampled and tested. In order to assign Class RB1a to a basin-fill deposit, the source must satisfy the overall requirements outlined in Section 3.1.1.

<u>Class</u>	<u>Explanation</u>
RB1b	Basin-fill sources containing materials suitable for use as road-base aggregates; based on correlation with Class RB1a source areas.

Class RB1b basin-fill deposits are correlated to tested RB1a deposits on the basis of limited laboratory sieve analysis data and field observations. Field observations included petrographic and grain-size analyses which provided data on lithology of adjacent source rock and general amounts and lithologies of gravel present in the basin-fill units. Photogeologic interpretations were also used to correlate Class RB1b deposits to RB1a deposits. Specific geomorphological parameters included surface texture, drainage patterns, relative relief, and topographic profiles.

<u>Class</u>	<u>Explanation</u>
RBII	Potential basin-fill sources of materials suitable for use as road-base aggregates; based on photogeologic interpretations, field observations, and limited or inconclusive sieve analysis and/or abrasion data.

Class RBII includes poorly defined, basin-fill aggregate sources. Field observations and inconclusive field and laboratory data indicate these deposits may be potentially acceptable for use as road-base aggregate sources.

All classifications are based on limited data. Additional field reconnaissance, testing, and case history studies are needed to

confirm adequacy, delimit exact areal boundaries, and refine chemical and physical characteristics.

3.2 SOURCES OF ROAD-BASE AGGREGATES

Only basin-fill units have been delineated as potential sources of road-base aggregates in the Delamar Valley study area (Drawing 2). The study approach in the evaluation of road-base aggregates emphasized the analysis of basin-fill deposits and dictated that only previously tested, crushed-rock sources be discussed and classified. Although there are no previously tested, acceptable rock sources delineated in Delamar Valley, untested rock units may be suitable as sources of crushed-rock aggregates.

3.2.1 Basin-Fill Sources

All three classes of road-base aggregates, Class RB1a, RB1b, and RB1I, are present in the basin-fill deposits of Delamar Valley (Drawing 2).

3.2.1.1 Class RB1a

All Class RB1a deposits within the study area are located along the eastern margin of the valley adjacent to the Delamar Mountains and the southern extent of the Burnt Springs Range. The Class RB1a deposit located against the northern boundary by the Burnt Springs Range extends north into Dry Lake Valley (E-TR-47-DL).

There are seven Class RB1a basin-fill deposits within the study area, all of which are alluvial fan units (Aaf). These basin-fill deposits generally consist of poor- to well-graded, sub-angular to subrounded sandy gravel. The gravel content of these deposits ranges from a low of 31 percent to a high of 71 percent but is generally 40 to 60 percent. Sand content ranges from 23 to 57 percent. Silt and clay content (below the overburden layer) ranges from a low of three percent to a high of 16 percent, but is generally between five to eight percent. Class RB1a basin-fill sources commonly consist of 25 to 94 percent carbonate clasts, 60 to 84 percent volcanic clasts, and 43 to 92 percent quartzite clasts. Carbonate and quartzite clasts are concentrated in Class RB1a deposits in the east-central part of the valley adjacent to the Delamar Mountains and in the deposit that lies adjacent to the Burnt Springs Range near U.S. Highway 93. Volcanic clasts are abundant in the northern and southern parts of the valley.

It has been observed that variations in grain-size gradations occur within a deposit depending on sample location. In general, gradations within a deposit are finer near the valley axis and coarser near mountain fronts. Due to access restrictions, samples were generally collected at distal and medial locations within each deposit.

The gradation of Class RB1a deposits approximates the grain-size distribution requirements stated in Section 3.1.1 (Figure 4). The different RB1a deposits generally share the same gradation

REQUIRED GRAIN-SIZE DISTRIBUTION ENVELOPE FOR TYPE I CLASS A, ROAD-BASE AGGREGATES (NEVADA STATE DEPARTMENT OF HIGHWAYS, 1976).

GRAIN-SIZE DISTRIBUTION ENVELOPE OF BASIN-FILL AGGREGATES POTENTIALLY SUITABLE FOR ROAD BASE.

FIGURE 4

characteristics; some cobbles and coarse gravel (oversized material) are present, gravel passing the 1.5-inches sieve is deficient, and fine gravel and sand passing 1-inch to No. 4 sieves are within design gradation requirements. There are two exceptions to the RB1a gradation trends. The deposit sampled in the north at locations 206 through 208 has a slight excess of sand passing the No. 4 and No. 8 sieves. The RB1a deposit at locations 226 through 228 (east-central portion of the valley) is deficient in gravels passing the 1-inch to 0.75-inch sieves. Material greater than 2 inches can be crushed and used to produce additional aggregates of all sizes. Additional minor processing of all RB1a deposits will be necessary to conform to the gradation requirements.

Laboratory abrasion tests performed on samples from all Class RB1a deposits show a narrow range of 26.3 to 31.8 percent wear. Laboratory MgSO_4 soundness tests performed on a selected group of coarse Class RB1a deposits yielded results ranging from 5.1 to 20.8 percent loss. Except for the one high soundness test loss of 20.8 percent, these test results are within acceptable values for abrasion and soundness.

The areal extent of the Class RB1a deposits ranges from approximately 0.5 to 2.0 mi^2 (1.3 to 5.2 km^2). The thickness of these Class RB1a deposits has been estimated to be at least 25 feet (7.6 m). Generally, 60 to 90 percent of the material in these deposits will be suitable for use as road base aggregates.

3.2.1.2 Class RBib

Class RBib basin-fill sources consist of alluvial and stream-channel deposits that have been correlated to Class RBia deposits and, therefore, are considered to contain material acceptable for use as road-base aggregates. These deposits occur only on the east side of the valley adjacent to the Delamar Mountains and the Burnt Springs Range. Class RBib basin-fill deposits include six alluvial fan deposits (Aaf) and one stream-channel deposit (Aal). The deposits of this class are generally all adjacent to Class RBia deposits.

Since Class RBib basin-fill deposits are correlated to Class RBia deposits, they possess the same general characteristics as the RBia deposits. These characteristics are poorly to well-graded, subangular to subrounded sandy gravel and gravelly sand which consist of predominantly carbonate and volcanic clasts with minor amounts of quartzite clasts.

Although variations in grain-size gradations will occur, depending on sample location within the deposit and the proximity of the deposit to its source area, Class RBib deposits are interpreted to have gradation distributions similar to RBia deposits.

The Class RBib deposits vary in surface area from approximately 0.2 to 3.3 mi² (0.5 to 8.5 km²). It is estimated that the material sampled from these deposits and described above extends to a depth of at least 25 feet (7.6 m). Generally, 60 to 90 percent of the material will be suitable for use as road-base aggregates.

3.2.1.3 Class RBII

Class RBII basin-fill aggregate sources are alluvial units that are potentially acceptable for use as road base. These deposits have been classified on the basis of limited field and laboratory data collected during this and other Ertec studies.

Class RBII deposits are eight widely spaced deposits located along the southeastern portion of the valley adjacent to the Delamar Mountains; in the west-central portion of the valley, adjacent to the South Pahroc Range; and in the northeastern portion of the valley, adjacent to the Burnt Springs Range. All of the Class RBII deposits are alluvial fan units (Aaf).

Limited laboratory and field data used to define the Class RBII deposits in the southeastern portion of the valley indicate that they consist of sandy gravel and gravelly sand and are composed predominantly of volcanic clasts with minor amounts of carbonate and quartzite clasts. However, there may be considerable variations from this general description within individual deposits.

The Class RBII deposits on the west side of the valley are known, on the basis of limited field data, to be composed of gravelly sand with abundant volcanic clasts. The total areal extent of the RBII deposits is approximately 25 mi² (64.6 km²).

4.0 CONCRETE AGGREGATES EVALUATION

4.1 STUDY APPROACH

The purpose of the concrete aggregates evaluation is to determine the suitability of aggregates within Delamar Valley for use in concrete. To accomplish this, two objectives have been established:

1. Evaluate the basic physical and chemical characteristics of the aggregates; and
2. Determine the concrete making properties of the aggregates.

The study approach required to achieve these objectives included a review of previous Ertec Verification (FN-TR-27-DM-I and II) and aggregate reports (FN-TR-20D and FN-TR-37-a) for Delamar Valley. This data base helped define the scope of the concrete aggregates investigation and included office and field photo-geologic and topographic interpretations, field reconnaissance, and collection and laboratory testing of basin-fill samples.

4.1.1 Requirements for Concrete Aggregates

The following requirements for aggregates and concrete (made using these aggregates) were established using criteria from the American Society of Testing and Materials (1979), the "Concrete Manual" prepared by the United States Department of the Interior (1975) and Milos Polivka (1981, personal communication).

1. Aggregates

- o Gradation - The aggregate gradation specifications used by the American Society of Testing and Materials (1979; C 33) were selected for evaluating the samples tested. These grading specifications follow.

Coarse Aggregates

<u>Sieve Size</u>	<u>Percent Passing by Weight</u>	<u>Sieve Size</u>	<u>Percent Passing by Weight</u>
2 inches	100	1 inch	100
1.5 inches	95-100	0.75 inch	90-100
1 inch	---	0.5 inch	---
0.75 inch	35-70	0.375 inch	20-55
0.50 inch	---	No.4	0-10
0.375 inch	10-30	No.8	0-5
No.4	0-5		

Fine Aggregates

<u>Sieve Size</u>	<u>Percent Passing by Weight</u>
0.375 inch	100
No.4	95-100
No.8	80-100
No.16	50-85
No.30	25-60
No.50	10-30
No.100	2-10
No.200	

- o Abrasion - Los Angeles Machine abrasion losses for coarse aggregates are not to exceed 50 percent.
- o Soundness - Five-cycle magnesium sulfate (MgSO_4) soundness losses are not to exceed 18 percent and 15 percent for coarse and fine aggregates, respectively. Although not a requirement for the evaluation, five-cycle sodium sulfate (Na_2SO_4) soundness tests are performed on samples that failed MgSO_4 testing. Resultant losses are not to exceed 12 percent and 10 percent for coarse and fine aggregates, respectively.
- o Reactivity - Aggregates are to be nonreactive to alkali-silica and alkali-carbonate rock tests. Results are incomplete and will be submitted as an addendum to this report.

2. Concrete

- o Compressive Strength - The primary concrete requirement is a 28-day compressive strength equal to or greater than 6500 psi.

- o Static Modulus of Elasticity - Values of 3 to 6 million psi at 28 days required.
- o Splitting Tensile Strength - Values of 10 percent or less of the compressive strength at 28 days required.
- o Ultimate Drying Shrinkage - Values of 0.03 to 0.10 percent (300 to 1000 millionths) required.

4.1.2 Data Acquisition and Analysis

4.1.2.1 Office Studies

Office studies for the concrete aggregates evaluation required preliminary basin-fill and rock unit differentiation based upon photogeologic interpretations and published topographic and geologic maps. All available data on basin-fill, grain-size gradations were compiled to estimate gravel content for the defined basin-fill units. All available test data on the aggregate properties of basin-fill and rock units were compiled to select sample locations in units previously tested and found preliminarily acceptable for use as concrete aggregate sources.

4.1.2.2 Field Studies

The field program involved backhoe excavation of five trenches selected during office studies and initial field reconnaissance; all the trenches were excavated to obtain samples of coarse and fine aggregates (gravel and sand).

Due to gradation variability in basin-fill deposits, field limits of 30 percent or more gravel and 15 percent or less silt and clay were established as basic aggregate grain-size distribution requirements. Gravel is defined as coarse aggregates which pass

the 3.0-inch (75-mm) sieve and are predominantly retained on a No. 4 (4.75-mm) sieve. Silt and clay particles are defined as material passing through a No. 200 sieve (0.0029-inch [0.075-mm]).

The five trenches excavated to collect basin-fill samples for the evaluation of concrete aggregates were grouped into a set 150 feet apart (46 m) to characterize an individual basin-fill unit. Trenches were excavated to depths ranging from 12 to 15 feet (3.7 to 4.6 m). Bulk representative samples averaged 400 pounds (182 kg) per trench.

Field studies also included 37 petrographic and grain-size data field stops and valley-wide photogeologic field reconnaissance. These analyses were performed to supplement and confirm the office studies and to provide a broader data base for lithologic and gradation correlations of basin-fill units.

4.1.2.3 Laboratory Testing

The laboratory aggregate testing program was performed in two phases. The first phase consisted of standard tests for determining the basic properties of the aggregates and included the following:

- o Unit Weights and Voids in Aggregates;
- o Standard Specifications for Concrete Aggregates;
- o Soundness of Aggregates, Magnesium Sulfate (MgSO_4) and Sodium Sulfate (NaSO_4);
- o Sieve Analysis by Washing, less than No. 200 fraction;
- o Fineness Modulus;

- o Specific Gravity and Absorption, Coarse and Fine Aggregates;
- o Resistance to Abrasion, Los Angeles Machine;
- o Sieve Analysis, Coarse and Fine Aggregates; and
- o Petrographic Examination of Aggregates for Concrete.

Generally, these tests were performed on aggregates from different locations within the same sources previously tested and identified as the most promising in the VSARS program. This repetitive testing was done to confirm the suitability of aggregates for concrete (see Section 4.1.1, Requirements for Concrete Aggregates). Table 1 lists the number of tests completed in Delamar Valley.

The second phase of the testing consisted of an evaluation of the concrete-making properties of the aggregates when used in the following three trial (check) concrete mixes:

- Mix 1 - 7.5 sacks (94 pounds per sack) of cement per cubic yard of concrete with 1.5-inches maximum aggregate size;
- Mix 2 - 8.5 sacks (94 pounds per sack) of cement per cubic yard of concrete with 1.5-inches maximum aggregate size; and
- Mix 3 - 8.5 sacks (94 pounds per sack) of cement per cubic yard of concrete with 0.75-inch maximum aggregate size and a superplasticizer.

In all three trial mixes, fly ash, as a pozzolan, replaced 20 percent of the cement by weight. All concrete trial mix design criteria are presented in Table 2. Samples were collected for one basin-fill (coarse and fine aggregates) trial mix. Material greater than 1.5 inches was crushed to conform to gradation

CONCRETE TRIAL MIX DESIGN CRITERIA
DELAMAR VALLEY, NEVADA

29 MAY 81

TABLE 2

requirements. If necessary, coarse and fine aggregates were processed to conform to gradation requirements.

The following tests were performed to evaluate fresh and hardened properties of concrete made from Delamar Valley aggregates:

Fresh Properties

- o Unit Weight, Yield and Air Content of Concrete;
- o Slump of Portland Cement Concrete;
- o Air Content of Concrete, Volumetric Method;
- o Making and Curing Concrete Specimens;
- o Making and Testing Accelerated Cure Concrete Compression Test Specimens; and
- o Selecting Proportions for Normal and Heavyweight Concrete.

Hardened Properties

- o Compressive Strength of Cylindrical Concrete Specimens;
- o Length Change of Hardened Cement Mortar and Concrete;
- o Potential Alkali-Silica Reactivity, Mortar-Bar Method;
- o Static Modulus of Elasticity of Concrete in Compression;
- o Splitting Tensile Strength of Cylindrical Concrete Specimens;
- o Potential Alkali-Carbonate Rock Reactivity, Length Change Method; and
- o Coefficient of Linear Thermal Expansion of Concrete.

The results of all tests summarized in Table 1 are important to the concrete aggregates evaluation, but hardened concrete properties are considered the most significant (see Section 4.1.1, Requirements for Concrete Aggregates). Although the primary requirement for concrete is a 28-day compressive strength of

6500 psi, one-day (accelerated), seven-day, and 90-day tests were done to determine the range of compressive strength values. In order to compare different aggregate sources, 28-day compressive strengths of Mix 3 were always used.

Occasionally, fresh concrete properties varied from design concrete specifications and may have affected hardened concrete test results. If known or significant, the causative factor and its effect on test results are mentioned in the discussions on sources of concrete aggregates (Section 4.2.1).

The scope of the study did not allow sample collection and laboratory testing of all potential basin-fill and rock concrete aggregate sources. Existing data and field petrographic and grain-size analyses were used to correlate lithologic and gradation properties to basin-fill units which were not sampled. An important element of this correlation procedure was the use of aerial photography to help delineate the lateral extent of basin-fill deposits. Photogeologic field observations ascertained geomorphological and topographical relationships of basin-fill units and the source rock lithology and distribution of predominantly gravelly materials.

No rock sources were examined in Delamar Valley, and limited laboratory and field data prevented confident correlations of tested sources outside the study area.

4.1.3 Presentation of Results

Results of the concrete aggregates evaluation are presented in the form of text, tables, figures, 1:62,500 scale drawings, and appendices. Drawing 1 is a location map showing the position in the study area of all data points used in the Detailed Aggregate Resources Study. All data points are grouped by study type and assigned categorized map numbers (see Section 3.1.3).

Drawing 3 presents the locations of the potential basin-fill concrete aggregate sources, DARS trenches, and field petrographic and grain-size data stops in the study area. Geologic unit symbols used in Drawing 3 relate to standard geologic nomenclature whenever possible. A conversion table relating these symbols to the geologic unit nomenclature used in other Ertec reports is contained in Appendix Table F-3.

A solid contact line separates basin-fill and rock units in Drawing 3 to differentiate these two basic material types. Basin-fill contacts are derived from photogeological mapping with limited field reconnaissance and are also dashed. Rock contacts were not delineated because of a lack of or limited laboratory and field data.

Classifications of potential basin-fill concrete aggregate sources are distinguished by different patterns and are emphasized by a dark background tone.

The appendices contain tables that summarize the basic field data collected during the course of the study and the subsequent

laboratory test procedures and results. Appendices A and B contain DARS trench data and petrographic and grain-size data, respectively. Appendix C contains representative trench logs. Appendix Table D-2 presents a laboratory testing flow diagram for the concrete aggregates evaluation. Appendix E presents the chemical analyses of cement, fly ash, and water used in making all concrete trial mixes. Appendix F includes three tables describing soil classification, caliche development, and geologic unit cross reference.

4.1.4 Classification of Concrete Aggregates

A classification system was designed to present the most likely basin-fill and crushed-rock concrete aggregate sources. It was developed from an evaluation as well as from an extrapolation of all available data. Data include laboratory test results (compressive strength of concrete and grain-size, abrasion, and soundness of aggregates) and geomorphological and compositional correlations.

The classification system groups potential aggregate sources into three categories:

1. Aggregate sources which were used in concrete mixes - Class CA1 and Class CA2;
2. Aggregate sources which were subjected to basic aggregate tests - Class CB; and
3. Untested aggregate sources which were correlated to Classes CA1, CA2, or CB - Class CC1 and Class CC2.

The classification is presented in hierarchy form; classification of the highest potential source areas is described first,

and classification of the lowest potential source areas is described last.

<u>Class</u>	<u>Explanation</u>
CA1	Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths equal to or greater than 6500 psi using Mix 3 (Section 4.1.2).
CA2	Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths less than 6500 psi using Mix 3 (Section 4.1.2).

The Classes CA1 and CA2 describe those specific sources where basin-fill or crushed-rock aggregates have been collected and used in making trial mix batches of concrete. Following appropriate ASTM standards, concrete cylinders containing the collected aggregates were made, cured, and tested for various hardened concrete properties. The class is divided into two categories by 28-day compressive strength test results.

Generally, aggregates from each potential source area have been tested previously during the VSARS program. Confirmation testing that includes gradation, abrasion, and soundness tests was performed when applicable to ensure the continued acceptability of a sample for use in concrete. Abrasion and MgSO_4 soundness values do not exceed coarse aggregate requirements specified in Section 4.1.1. Tested samples of fine aggregates used in the concrete trial mixes consistently have MgSO_4 soundness losses

exceeding the required 15 percent maximum, however, NaSO_4 soundness losses generally do not exceed 10 percent.

ClassExplanation

CB

Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on acceptable laboratory aggregate test results.

The Class CB describes those source areas that have been sampled and tested only for grain-size gradation, abrasion, and magnesium sulfate soundness. Trial concrete mixes were not made. Gradation, abrasion, and soundness values specified in Section 4.1.1 were used to assign this classification to an aggregate source.

ClassExplanation

CC1

Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on correlation with Class CA1 or CA2 areas.

CC2

Basin-fill sources of aggregates potentially suitable for use in concrete; based on correlation with Class CB areas.

Untested Class CC deposits are correlated to tested Class CA or CB deposits on the basis of field observations and limited field and laboratory test results. Class CC basin-fill deposits consist of units of the same apparent relative age as Class CA and CB deposits.

Field observations and petrographic and grain-size analyses provided correlative data on lithology of adjacent source rock

and lithology and general amounts of gravel present in the basin-fill units. Photogeologic interpretations were also used to correlate Class CC basin-fill deposits to Class CA or CB basin-fill deposits. Specific geomorphological parameters correlated during the procedure included surface texture, drainage patterns, relative relief, and topographic profiles.

All classifications are based on limited data. Additional field reconnaissance, testing, and case history studies are needed to confirm adequacy, delimit exact areal boundaries, and refine chemical and physical properties.

4.2 SOURCES OF CONCRETE AGGREGATES

Only basin-fill deposits have been classified as potential sources of concrete aggregates in Delamar Valley. The study approach in the evaluation of concrete aggregates emphasized the analysis of basin-fill deposits and dictated that only previously tested, acceptable crushed-rock sources be sampled and/or evaluated. Although there are no previously tested, acceptable rock sources delineated in Delamar Valley, untested rock units may be suitable as sources of crushed-rock aggregates.

4.2.1 Basin-Fill Sources

Basin-fill sources of concrete aggregates are grouped into four classes. Deposits defined on the basis of laboratory test data are included in Class CA1 and Class CB. Untested basin-fill deposits correlated to deposits with test data are in Classes CC1 and CC2.

4.2.1.1 Class CA1

There is one Class CA1 basin-fill concrete materials source identified within the study area. This deposit is located on the east side of the valley adjacent to the Delamar Mountains.

1. The Class CA1 basin-fill source is an alluvial fan deposit (Aaf) located adjacent to the Delamar Mountains between latitudes 37°15'N and 37°30'N (Drawing 3). This deposit consists mainly of poorly graded, sandy gravel. The gravel ranges from 58 to 71 percent of the deposit (excluding cobbles and boulders), and the sand ranges from 23 to 35 percent. Cobbles and boulders comprise about seven percent of the total material within the deposit. Silt and clay comprise from six to nine percent of the deposit.

The gravel clasts sampled from the Class CA1 deposit are typically subangular to subrounded in shape. Approximately 61 percent of the gravel clasts are of satisfactory physical quality; 30 percent are porous, weak, and internally fractured and are of fair physical quality; and about nine percent are soft or highly porous and are of poor quality. The collected gravel sample is composed of approximately 66 percent dolomite, 11 percent limestone and dolomitic limestone, five percent quartzite and quartzose sandstone, and 16 percent coating material, volcanic, chert, and tuffaceous material. About 57 percent of the gravel clasts are partially or completely coated by calcareous material. The dolomite and dolomitic limestone clasts may be susceptible to a deleterious degree to the alkali-carbonate reaction. Volcanic, chert, and tuffaceous materials are susceptible to the alkali-silica reaction.

The sand particles from the sampled Class CA1 deposit are typically angular to subrounded in shape and are generally similar

in composition, but not quality, to the gravel clasts within the deposits. Approximately 38 percent of the sampled sand particles are satisfactory in physical quality; 49 percent are porous, weak, or internally fractured and are of fair physical quality; and about 13 percent are soft, highly porous particles and are of poor quality. All the sand is considered to be marginally susceptible to a deleterious degree to the alkali-carbonate reaction and susceptible to the alkali-silica reaction.

The percentages of coarse aggregates passing the 1-inch to No. 4 sieves within the Class CA1 deposit conform to the design gradation requirements (Figure 5). The percentages of coarse aggregates passing the 2- to 1.5-inch sieves are deficient, and oversize clasts are available for crushing. The percentages of fine aggregates do not conform to design gradation requirements. There is a deficiency of coarse sand passing the No. 8 sieve and an excess of fine sand passing the No. 50 to No. 200 sieves. Processing will be necessary to bring the deposit within gradation requirements. Variations in grain-size gradations will occur within the deposit depending on proximity to the source area. In general, this source is relatively fine grained near the valley axis and coarse grained adjacent to the mountain fronts.

A coarse aggregate sample from this Class CA1 deposit was subjected to laboratory abrasion and MgSO_4 soundness tests and yielded losses of 29.1 and 5.1 percent, respectively. These values for abrasion and soundness are well within acceptable

REQUIRED GRAIN-SIZE DISTRIBUTION ENVELOPES FOR COARSE AND FINE AGGREGATES USED IN CONCRETE (AMERICAN SOCIETY FOR TESTING AND MATERIALS, 1978, C 33; THE RECOMMENDED GRADATIONS FOR AGGREGATES WITH 1.5 AND 0.75 INCH MAXIMUM SIZE ARE COMBINED INTO ONE ENVELOPE).

GRAIN-SIZE DISTRIBUTION ENVELOPES OF BASIN-FILL COARSE AND FINE AGGREGATES POTENTIALLY SUITABLE FOR CONCRETE.

ranges for coarse concrete-construction-material use. The fine aggregate sample from this Class CA1 deposit was subjected to both MgSO_4 and NaSO_4 soundness tests. The sample failed the MgSO_4 soundness test with a 23.3 percent loss but passed the NaSO_4 soundness test with a 3.3 percent loss.

Concrete (Mix 3) made using the aggregates from the Class CA1 deposit had a 28-day compressive strength of 7690 psi and a 90-day compressive strength of 8785 psi. Concrete trial Mixes 1 and 2 yielded 28-day compressive strengths of 4545 psi and 5525 psi, respectively (Table 3). The air content of Mix 1 (9.0 percent) was higher than the maximum air content as specified by the mix design (6.0 percent) and may have caused a lowering of the compressive strengths of this mix. Fresh concrete properties and hardened concrete test results (chord modulus of elasticity, splitting tensile strength, drying shrinkage) are also included in Table 3. All test results for hardened concrete except for Mix 1 are within or exceed the requirements mentioned in Section 4.1.1.

The areal extent of the Class CA1 deposit is approximately 0.7 mi^2 (1.8 km^2). It is estimated that the material sampled from this deposit and described above extends to a depth of at least 25 feet (7.6 m). It is also estimated that this deposit has a yield of 75 to 80 percent after gradation deficiencies, handling, poor-quality constituents, and silt and clay losses.

CONCRETE TRIAL MIX TEST RESULTS
DM-A-(16-20)
DELAMAR VALLEY, NEVADA

29 MAY 81

TABLE 3

1 OF 1

4.2.1.2 Class CB

Class CB basin-fill aggregate sources are alluvial deposits that have been sampled and laboratory tested and, on the basis of test results, are considered to be potential sources of concrete aggregates. Class CB deposits have not been used in concrete trial mixes. Test results show that these deposits contain at least 30 percent gravel clasts of all sizes (No. 4 sieve size to 3-inches), have less than 50 percent abrasion wear, and where applicable, have less than 18 percent loss when subjected to a $MgSO_4$ soundness test.

There are five Class CB sources along the east side of the study area, and all are alluvial fan (Aaf) deposits. Four are located adjacent to the Delamar Mountains, and one is located near U.S. Highway 93 adjacent to the Burnt Springs Range.

Class CB basin-fill deposits generally consist of poorly to well-graded, subangular to subrounded gravelly sand and sandy gravel. The gravel content of most Class CB deposits ranges from about 30 to 60 percent, and the silt content ranges from four to 16 percent. Most deposits are composed of a few to 69 percent carbonate and quartzite clasts and eight to 84 percent volcanic clasts.

The percentages of coarse aggregates passing the 1-inch to No. 4 sieves within the Class CB deposit conform to design gradation requirements (Figure 6). The percentages of coarse aggregates passing the 2- to 1.5-inches sieves are slightly deficient, and

REQUIRED GRAIN-SIZE DISTRIBUTION ENVELOPES FOR COARSE AND FINE AGGREGATES USED IN CONCRETE (AMERICAN SOCIETY FOR TESTING AND MATERIALS, 1978, C 33; THE RECOMMENDED GRADATIONS FOR AGGREGATES WITH 1.5 AND 0.75 INCH MAXIMUM SIZE ARE COMBINED INTO ONE ENVELOPE).

GRAIN-SIZE DISTRIBUTION ENVELOPES OF BASIN-FILL COARSE AND FINE AGGREGATES POTENTIALLY SUITABLE FOR CONCRETE.

FIGURE 6

oversize material is available for crushing. Although the percentage of coarse sand generally meets designs requirements, the percentage of fine sand passing the No. 50 to No. 100 sieves is excessive. Variations in grain-size gradations will occur within the deposit depending on proximity to the source area. In general, the deposits are relatively finer-grained near the valley axis and coarser-grained near the mountain fronts.

Laboratory abrasion tests performed on samples from all Class CB deposits resulted in fairly low percent wear values ranging from 26.3 to 31.8 percent. MgSO_4 soundness tests performed on the coarse aggregates from two of the Class CB samples resulted in values of 12.7 and 17.4 percent loss.

The areal extent of Class CB deposits ranges from 0.6 to 1.1 mi^2 (1.6 to 2.8 km^2). It is estimated that the material sampled from these deposits extends to a depth of at least 25 feet (7.6 m) and will have a yield of 60 to 80 percent.

4.2.1.3 Class CC1

The Class CC1 deposit within the study area is located on the east side of the valley adjacent to the Delamar Mountains. It is an alluvial fan unit that has been correlated to the Class CA1 deposit on the basis of geomorphological and compositional similarities.

The Class CC1 deposit is therefore considered to be a potential source of concrete aggregate consisting of poorly graded, subangular to angular sandy gravel of generally satisfactory

physical quality. The lithology of the deposit is predominantly quartzite, limestone, and dolomite with trace amounts of other rock types. The areal extent of the Class CC1 deposit is 1.3 mi² (3.4 km²).

4.2.1.4 Class CC2

Class CC2 basin-fill aggregate sources are alluvial deposits that have been correlated to Class CB concrete aggregate sources on the basis of geomorphological and compositional similarities. These deposits are therefore assumed to contain material similar in size and composition to Class CB deposits. Class CC2 deposits are located along the east side of the valley adjacent to the Delamar Mountains and have an areal extent ranging from 0.2 to 3.3 mi² (0.5 to 8.5 km²).

5.0 CONCLUSIONS

Results of the Detailed Aggregate Resources Study indicate that there are sufficient quantities of aggregates available for the construction of the MX missile system in the Delamar Valley study area.

Good to high quality basin-fill coarse aggregates are present along the east side of the valley. Sufficient quantities of poor to satisfactory quality, fine aggregates are present in basin-fill deposits in the valley. After shelter layouts are finalized, potential borrow areas can be delineated based on the results of this study.

Although most rock will supply acceptable coarse aggregates, no sources are delineated in this study. Sufficient quantities of basin-fill aggregates within the valley will probably make processing of crushed-rock aggregates unnecessary.

As discussed in the report, field studies placed an arbitrary cut-off limit of a minimum of 30 percent gravel for the source to be considered for road-base or concrete aggregates. Nevertheless, basin-fill deposits with less than 30 percent gravel are also probably potentially suitable for use as aggregates. However, yield from such sources will be low and extensive processing and/or blending will be required to satisfy the gradation requirements.

5.1 ROAD-BASE AGGREGATES

5.1.1 Class RB1a Sources

Seven basin-fill deposits consisting of good- to high-quality coarse aggregates acceptable for road base have been located within the study area. They are confined to the east side of the valley and have an areal extent of approximately 6.8 mi² (17.6 km²).

Gradation analyses indicate that, where sampled, the deposits approximate ASTM standards and DARS requirements. Sand and fine gravel sizes are within design gradation requirements. Gravels passing the 1.5- to 1-inch sieves is deficient. Crushing and blending the coarse gravels and cobbles should bring individual deposits within design gradation requirements. In addition, grain-size variations will occur depending on sample location within the deposit. Generally, finer grained material can be obtained nearer the valley axis, and coarser grained material can be obtained near mountain front source areas.

Abrasion and soundness results on tested samples are also within ASTM standards and DARS requirements.

5.1.2 Class RB1b Sources

Seven basin-fill deposits within the study area are defined as potential sources of good- to high-quality coarse aggregates for use as road-base construction material. Geomorphological and compositional similarities were used to correlate these units to tested RB1a deposits. The units include alluvial fan deposits (Aaf) and one stream channel deposit (Aal). All are

confined to the east side of the valley. Their total areal extent is approximately 12 mi² (31.1 km²).

5.1.3 Class RBII Sources

Eight potential road-base aggregate sources defined by limited field and laboratory data are present throughout the study area. All deposits are alluvial fans, consist predominantly of sandy gravel or gravelly sand, and are compositionally similar to Class RB1a and RB1b deposits. These deposits have a total areal extent of approximately 25 mi² (64.8 km²).

5.2 CONCRETE AGGREGATES

5.2.1 Class CA1 Sources

One alluvial fan basin-fill deposit consisting of good- to high-quality aggregates that produced concrete with 28-day compressive strengths equal to or greater than 6500 psi has been delineated within the study area. Chord modulus of elasticity, splitting tensile strength, and drying shrinkage results generally conform to the standard concrete requirements.

Gradation results indicate that, where sampled, the deposit approximates ASTM standards and DARS requirements. Typically, percentages of medium and fine gravel (1-inch to No. 4 sieves) conform to gradation specifications, but there is a lack of coarse gravel passing the 2- to 1.5-inch sieves. The fine aggregate samples generally contain a deficiency of coarse sand passing the No. 8 sieve and an excess of fine sand passing the No. 50 to No. 200 sieves. Processing of basin-fill deposits

will be necessary to bring gradations within design requirements. Crushing of over-sized materials will produce more aggregates of all sizes. Wasting will remove excess fine sand. In addition, variations in grain-size gradation will occur within the deposit depending on proximity to the source area. Aggregates are relatively finer grained near the valley axis and coarser grained near the mountain fronts.

Results of abrasion and soundness tests performed on coarse aggregates from the Class CA1 deposit are also within specified ASTM and DARS requirements. The fine aggregates within the deposit are generally of lower quality (high MgSO_4 soundness losses) but results are inconclusive regarding their use as concrete construction material. The Class CA1 deposit is located on the east side of the valley and has a total areal extent is approximately 0.7 mi^2 (1.8 km^2).

5.2.2 Class CB Sources

Five basin-fill deposits consisting of good- to high-quality coarse aggregates potentially acceptable for use as concrete construction material were delineated within the study area. These deposits are all alluvial fan units (Aaf) and are confined to the east side of the valley. Their total areal extent is approximately 4 mi^2 (10.4 km^2). No concrete trial mixes were made, but gradation, abrasion, and soundness test results on samples from these deposits were generally within acceptable ranges as specified by ASTM standards and DARS requirements.

5.2.3 Class CC1 Sources

One basin-fill alluvial fan unit in the study area is classified as a potential source of concrete aggregates. The unit is correlated to the Class CA1 source based on geomorphological and compositional similarities. This deposit has a total areal extent of approximately 1.3 mi² (3.4 km²).

5.2.4 Class CC2 Sources

Several alluvial units located along the east side of the valley are classified as potential sources of concrete aggregates. Units were correlated to Class CB sources on the basis of geomorphological and compositional similarities. They have a total areal extent of approximately 7 mi² (18.1 km²).

6.0 RECOMMENDATIONS FOR FUTURE STUDIES

The conclusions of this Detailed Aggregate Resources Study of Delamar Valley, as enumerated in Section 5.0, are based on limited field and laboratory test results. However, the results presented in this report provide sufficient data for selecting potential borrow areas. After selection of the borrow areas, more extensive studies are required to further determine the characteristics of the aggregates.

6.1 SOURCES OF ROAD-BASE AGGREGATES

It is recommended that additional field exploration (backhoe or drilling) and detailed laboratory testing be performed. The laboratory tests should consist of sieve analysis, resistance to abrasion, CBR, and other appropriate tests as deemed necessary by the designers.

6.2 SOURCES OF CONCRETE AGGREGATES

It is recommended that additional field investigations (backhoe or drilling) and detailed laboratory testing be performed. The aggregate samples should be subjected to the following tests:

- o Sieve Analysis;
- o Resistance to Abrasion;
- o Soundness;
- o Specific Gravity and Absorption; and
- o Petrographic Examination of Aggregates for Concrete.

In addition, the following detailed tests using concrete made from these aggregates should be performed:

- o Compressive Strength;
- o Splitting Tensile Strength;
- o Flexural Strength;
- o Shrinkage;

- o Thermal Expansion;
- o Modulus of Elasticity;
- o Potential Alkali-Silica Reactivity;
- o Potential Alkali-Carbonate Rock Reactivity; and
- o Resistance of Concrete to Rapid Freezing and Thawing.

It is recommended that concrete trial mixes with different size aggregates and admixtures be made in order to assess the variation in compressive strength, durability, shrinkage, and thermal properties of concrete.

Limited testing performed during the Delamar Verification studies (FN-TR-27-DM-I and II) indicate that the potential for sulfate attack of soils on concrete is "negligible." However, it is recommended that additional studies be made to further evaluate the potential for sulfate attack of soils on concrete and determine the type of cement to be used in concrete.

APPENDIX A
SUMMARY OF FIELD AND LABORATORY TEST DATA

FIELD AND LABORATORY TEST DATA

Field observations and laboratory test data on samples collected at selected stations are presented in Table A-1. Field stations were established at various locations throughout the study area where detailed descriptions of potential basin-fill and fine aggregate sources were recorded. Detailed explanations for the column headings of Table A-1 are as follows:

<u>COLUMN HEADING</u>	<u>EXPLANATION</u>
MAP NUMBER	Map numbers are sequentially arranged identifiers of field stations occupied during the course of the aggregate study.
FIELD STATION	These designations are internal DARS identifiers of all field stations. Each one consists of a two-letter valley abbreviation followed by the letter A (aggregate trench).
LOCATION	The location column lists the geographic portion of the valley in which the field station is located (e.g., NE-northeast).
GEOLOGIC UNIT	The geologic unit listed is a term used to differentiate basin-fill deposits based on geomorphology. A geologic unit cross reference, outlining all units used, is included as Table F-3.
MATERIAL DESCRIPTION	Material descriptions are based on either field or laboratory USCS classifications using appropriate ASTM standards for basin-fill deposits. Coarse and fine aggregate gradations used in concrete trial mix designs are included at the end of each concrete aggregate trench group.
USCS SYMBOL	Appropriate field or laboratory ASTM standards are used to classify sampled

material. The Unified Soil Classification System is used in this study. Table F-1 contains detailed information on the USCS.

FIELD OBSERVATIONS

Boulders and/or Cobbles

The estimated occurrence of boulders and cobbles is based on an appraisal of the entire deposit. Cobbles have an intermediate diameter of 3 to 12 inches (8 to 30 cm); boulders have an intermediate diameter of 12 inches (30 cm) or more. Because of sample-size limitations, boulders were not generally sampled. Cobbles were representatively sampled for concrete aggregate evaluations but only generally sampled for road-base aggregate evaluations. Field observations of boulders and cobbles are important considerations for in-situ gradations only. Number percentages are equated to the following equivalent dry weight terms:

Rare - 1 - 4 percent
Few - 5 - 20 percent
Some - > 20 percent

Gravel

Coarse aggregate particles that pass a 3-inch (76-mm) sieve but are predominantly retained on a No. 4 (4.75 mm) sieve.

Sand

Fine aggregate particles that almost entirely pass a No. 4 sieve but are predominantly retained on a No. 200 (0.075 mm) sieve.

Fines

Soil particles that pass a No. 200 sieve (silt and clay).

Overburden Thickness (Feet)

Surficial soil overlying a usable aggregate deposit. Material generally consists of silt and sand with low concentrations of gravel. Numbers presented indicate thickness of deposit in feet.

Total Trench Depth (Feet)

Depth, in feet, of trench excavation used to collect aggregate samples. Depth followed by the letter R indicates that depth below which soil strength exceeded excavation capability. The common conditions for refusal (R) are calcium carbonate accumulation (caliche) and/or presence of oversized material.

Deleterious
Materials
(Material/Depth/
Stage)

Deleterious materials are substances that are potentially detrimental to concrete in service. Substances that may be present include: organic impurities, low density materials (ash, vesicle, pumice, cinders), amorphous silica (opal, chert, chalcedony), volcanic glass, caliche and clay coatings, mica, gypsum, pyrite, chlorite, friable materials, and aggregates that may react chemically or be affected chemically by other external influences. The most common deleterious material is calcium carbonate accumulation (caliche). When it is abundant, the interval(s) at which it occurs and the stage of development (Table F-2) are listed. Caliche can occur disseminated throughout a deposit, as lenses, and as discrete layers. The depth space is left blank when caliche is present throughout the deposit.

Plasticity
(Index)

Plasticity index (PI) is the range of water content, expressed as a percentage of the weight of the oven-dried soil (less than No. 40 sieve material), through which a soil behaves plastically. It is defined as the liquid limit minus the plastic limit. Field terms used to approximate plasticity index range include the following.

Plasticity PI

Wet Consistency

Slight (4-15)

Slightly sticky; after pressure, soil adheres to both thumb and finger but comes off cleanly. Does not appreciably stretch.

Medium (15-30)

Sticky; after pressure, soil adheres to both thumb and finger and tends to stretch somewhat before pulling apart from either digit.

High (>30)

Very sticky; after pressure, soil adheres strongly to both digits and is markedly stretched when digits are separated.

Hardness

Hardness determination is a field test used to identify materials that are soft or poorly bonded by estimating their resistance to crushing by impact with a

	rock hammer. Classification terms used include:
Soft	Hammer point indents deeply with firm blow.
Moderately Hard	Hammer point indents only shallowly with firm blow.
Hard	Hammer breaks hand-held sample with one firm blow.
Very Hard	Hammer breaks intact sample with many blows.
<u>Weathering</u>	Weathering is defined as any changes in color, texture, strength, chemical composition, or other properties of rock due to the effects of various atmospheric conditions. Field terms used to classify degree of weathering include: fresh, slight(ly), moderate(ly), or very weathered.

LABORATORY TEST DATA

Sieve Analysis
(ASTM C 136)

A sieve analysis is the determination of the proportions of particles existing within certain size ranges in granular material by separation on sieves of different size openings, expressed as a weight percent of the total sample. Numbers presented represent the percent of the sample passing through the stated sieve size. Sieve sizes include: 3-inch (75-mm), 2 1/2-inch (63-mm), 2-inch (50-mm), 1 1/2-inch (38.1-mm), 1-inch (25-mm), 3/4-inch (19-mm), 1/2-inch (12.5-mm), 3/8-inch (9.5-mm), No. 4 (4.75-mm), No. 8 (2.36-mm) No. 16 (1.18-mm) No. 30 (0.6-mm), No. 50 (0.3-mm), No. 100 (0.15-mm), No. 200 (0.075-mm).

Specific Gravity
and Absorption
(ASTM C 127 and 128)

In general, specific gravity is defined as the ratio of the weight in air of a unit volume of material to the weight in air of an equal volume of water. Absorption is the process by which a liquid is drawn into and tends to fill permeable pores in a porous solid body, also, the increase in weight of a porous

solid body resulting from the penetration of a liquid into its permeable pores. Specific definitions of bulk, bulk saturate-surface-dry (SSD), and apparent specific gravity, as well as absorption are contained in ASTM-E 12-70 and C 125, respectively.

Fineness Modulus

Fineness modulus is an empirical factor obtained by adding the total percentages of a sample of aggregate, retained on each of a specified series of sieves, and dividing the sum by 100.

Unit Weight

Unit weight is the weight of a unit volume of dry, rodded aggregate, commonly expressed as pounds per cubic foot (pcf).

Abrasion Test
(ASTM C 131)

The abrasion test is a method for testing resistance to wearing away by rubbing and friction, by placing a specified quantity of aggregates in a steel drum (the Los Angeles testing machine), rotating the drum 500 times, and determining the percent of material worn away.

Soundness Test
(ASTM C 88)

Soundness tests are used to determine resistance to large or permanent volume changes of aggregates by placing samples in saturated solutions of magnesium or sodium sulfate. The test furnishes information useful in studying resistance to weathering action, particularly when adequate service records of the material tested are not available. For concrete aggregate tests, magnesium sulfate soundness tests are run first. If the material fails this test, sodium sulfate soundness tests are performed.

Petrographic
Examination
(ASTM C 295)

A petrographic examination is a procedure used to identify the physical and chemical properties of aggregates that have a bearing on the quality of the material in consideration of its intended use. Typical properties analyzed include: description and classification of constituents, relative amounts of constituents, particle coatings, rock type, particle condition

and particle shape, texture and structure, color, mineral composition and heterogeneities, and presence of constituents known to cause deleterious chemical reactions in concrete.

Alkali Reactivity

Alkali-Silica ASTM C 227

A potential alkali-silica reactivity test evaluates the susceptibility of cement-aggregate combinations to expansive reactions involving the alkalis sodium and potassium by measurement of the increase (or decrease) in length of mortar bars containing the combination during storage under prescribed conditions of test.

Alkali-Carbonate ASTM Proposed Standard

A potential alkali-carbonate reactivity test evaluates the susceptibility of cement-aggregate combinations to expansive reactions involving the carbonates of dolomite (in certain calcitic dolomites and dolomitic limestones) by measurement of the increase (or decrease) in length of concrete specimens (prisms) containing the combination during storage under prescribed conditions of test. This test is a proposed ASTM standard and has not been formally approved by the American Society of Testing and Materials.

AGGREGATE USE CLASSIFICATION

Road Base Aggregates

- | | |
|-------|--|
| RB Ia | Basin-fill or rock sources containing materials suitable for use as road-base aggregates; based on acceptable laboratory aggregate test results. |
| RB Ib | Basin-fill sources containing materials suitable for use as road-base aggregates; based on correlation with Class RB Ia areas. |
| RB II | Potential basin-fill sources of materials suitable for use as road-base aggregates; based on photogeologic interpretations, field observations, and limited or inconclusive sieve analysis and/or abrasion data. |

Concrete
Aggregates

- CA1 Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths equal to or greater than 6500 psi.
- CA2 Basin-fill or rock sources containing aggregates that produced trial mix concrete with 28-day compressive strengths less than 6500 psi.
- CB Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on acceptable laboratory aggregate test results.
- CC1 Basin-fill or rock sources containing aggregates potentially suitable for use in concrete; based on correlation with Class CA1 or CA2 source areas.
- CC2 Basin-fill sources containing aggregates potentially suitable for use in concrete; based on correlation with Class CB source areas.
- FA Basin-fill sources containing fine aggregates used with crushed-rock samples for certain concrete trial mixes.

A microcopy resolution test chart (NBS 1963-A) is displayed. The chart features a grid of patterns of horizontal and vertical lines of varying thicknesses and spacings. Each pattern is labeled with a numerical value representing its resolution. The labels are arranged in a grid-like fashion, with some values appearing in a larger font than others. The values include 1.0, 1.1, 1.25, 1.4, 1.6, 1.8, 2.0, 2.2, 2.5, 2.8, 3.2, 3.6, 4.0, 4.5, 5.0, 5.6, 6.3, 7.1, 8.0, 9.0, 10.0, 11.2, 12.5, 14.0, 16.0, 18.0, 20.0, 22.4, 25.0, 28.0, 31.5, 36.0, 40.0, 45.0, 50.0, 56.0, 63.0, 71.0, 80.0, 90.0, 100.0, 112.0, 125.0, 140.0, 160.0, 180.0, 200.0, 224.0, 250.0, 280.0, 315.0, 360.0, 400.0, 450.0, 500.0, 560.0, 630.0, 710.0, 800.0, 900.0, 1000.0, 1120.0, 1250.0, 1400.0, 1600.0, 1800.0, 2000.0, 2240.0, 2500.0, 2800.0, 3150.0, 3600.0, 4000.0, 4500.0, 5000.0, 5600.0, 6300.0, 7100.0, 8000.0, 9000.0, 10000.0, 11200.0, 12500.0, 14000.0, 16000.0, 18000.0, 20000.0, 22400.0, 25000.0, 28000.0, 31500.0, 36000.0, 40000.0, 45000.0, 50000.0, 56000.0, 63000.0, 71000.0, 80000.0, 90000.0, 100000.0, 112000.0, 125000.0, 140000.0, 160000.0, 180000.0, 200000.0, 224000.0, 250000.0, 280000.0, 315000.0, 360000.0, 400000.0, 450000.0, 500000.0, 560000.0, 630000.0, 710000.0, 800000.0, 900000.0, 1000000.0, 1120000.0, 1250000.0, 1400000.0, 1600000.0, 1800000.0, 2000000.0, 2240000.0, 2500000.0, 2800000.0, 3150000.0, 3600000.0, 4000000.0, 4500000.0, 5000000.0, 5600000.0, 6300000.0, 7100000.0, 8000000.0, 9000000.0, 10000000.0, 11200000.0, 12500000.0, 14000000.0, 16000000.0, 18000000.0, 20000000.0, 22400000.0, 25000000.0, 28000000.0, 31500000.0, 36000000.0, 40000000.0, 45000000.0, 50000000.0, 56000000.0, 63000000.0, 71000000.0, 80000000.0, 90000000.0, 100000000.0, 112000000.0, 125000000.0, 140000000.0, 160000000.0, 180000000.0, 200000000.0, 224000000.0, 250000000.0, 280000000.0, 315000000.0, 360000000.0, 400000000.0, 450000000.0, 500000000.0, 560000000.0, 630000000.0, 710000000.0, 800000000.0, 900000000.0, 1000000000.0, 1120000000.0, 1250000000.0, 1400000000.0, 1600000000.0, 1800000000.0, 2000000000.0, 2240000000.0, 2500000000.0, 2800000000.0, 3150000000.0, 3600000000.0, 4000000000.0, 4500000000.0, 5000000000.0, 5600000000.0, 6300000000.0, 7100000000.0, 8000000000.0, 9000000000.0, 10000000000.0, 11200000000.0, 12500000000.0, 14000000000.0, 16000000000.0, 18000000000.0, 20000000000.0, 22400000000.0, 25000000000.0, 28000000000.0, 31500000000.0, 36000000000.0, 40000000000.0, 45000000000.0, 50000000000.0, 56000000000.0, 63000000000.0, 71000000000.0, 80000000000.0, 90000000000.0, 100000000000.0, 112000000000.0, 125000000000.0, 140000000000.0, 160000000000.0, 180000000000.0, 200000000000.0, 224000000000.0, 250000000000.0, 280000000000.0, 315000000000.0, 360000000000.0, 400000000000.0, 450000000000.0, 500000000000.0, 560000000000.0, 630000000000.0, 710000000000.0, 800000000000.0, 900000000000.0, 1000000000000.0, 1120000000000.0, 1250000000000.0, 1400000000000.0, 1600000000000.0, 1800000000000.0, 2000000000000.0, 2240000000000.0, 2500000000000.0, 2800000000000.0, 3150000000000.0, 3600000000000.0, 4000000000000.0, 4500000000000.0, 5000000000000.0, 5600000000000.0, 6300000000000.0, 7100000000000.0, 8000000000000.0, 9000000000000.0, 10000000000000.0, 11200000000000.0, 12500000000000.0, 14000000000000.0, 16000000000000.0, 18000000000000.0, 20000000000000.0, 22400000000000.0, 25000000000000.0, 28000000000000.0, 31500000000000.0, 36000000000000.0, 40000000000000.0, 45000000000000.0, 50000000000000.0, 56000000000000.0, 63000000000000.0, 71000000000000.0, 80000000000000.0, 90000000000000.0, 100000000000000.0, 112000000000000.0, 125000000000000.0, 140000000000000.0, 160000000000000.0, 180000000000000.0, 200000000000000.0, 224000000000000.0, 250000000000000.0, 280000000000000.0, 315000000000000.0, 360000000000000.0, 400000000000000.0, 450000000000000.0, 500000000000000.0, 560000000000000.0, 630000000000000.0, 710000000000000.0, 800000000000000.0, 900000000000000.0, 1000000000000000.0, 1120000000000000.0, 1250000000000000.0, 1400000000000000.0, 1600000000000000.0, 1800000000000000.0, 2000000000000000.0, 2240000000000000.0, 2500000000000000.0, 2800000000000000.0, 3150000000000000.0, 3600000000000000.0, 4000000000000000.0, 4500000000000000.0, 5000000000000000.0, 5600000000000000.0, 6300000000000000.0, 7100000000000000.0, 8000000000000000.0, 9000000000

APPENDIX B
SUMMARY OF FIELD PETROGRAPHIC
AND GRAIN-SIZE ANALYSES

FIELD PETROGRAPHIC AND GRAIN-SIZE ANALYSES

Field petrographic observations are presented in Table B-1. Field stations were established at various locations throughout the study area where detailed petrographic descriptions of potential basin-fill sources of aggregates were recorded. Detailed explanations for the column headings of Table B-1 are as follows:

<u>COLUMN HEADING</u>	<u>EXPLANATION</u>
MAP NUMBER	Map numbers are sequentially arranged identifiers of field petrographic stations occupied during the course of the aggregate study.
FIELD STATION	These designations are internal DARS identifiers of field petrographic designations.
LOCATION	The location column lists the geographic portion of the valley in which the field station is located (e.g., NE-northeast).
GEOLOGIC UNIT	The geologic unit listed is a term used to differentiate basin-fill deposits based on geomorphology. A geologic unit cross reference, outlining all units used, is included as Table F-3.
FIELD OBSERVATIONS	
<u>Clast Count</u>	Clast or petrographic counts are the main data collected during the field petrographic analysis. Data collected include lithology and percent present by size. Categorization by lithology is done to determine general percentages of nondeleterious and deleterious materials.
<u>Other Deleterious Clasts Present</u>	This column is reserved for recording additional types of materials present that are of poor quality for use as aggregate. Items mentioned include samples of rock types not sieved, counted, and described under clast count, such as: amorphous silica

(chert, opal, chalcedony), volcanic glass, mica, chlorite, friable materials, low density clasts (ash, vesicles, pumice, cinders), gypsum, pyrite, organic material, and coatings (clay and caliche).

Size Distribution

The estimated occurrence of boulders and cobbles is based on the appraisal of an entire deposit only if the materials are observed in the banks of prominent stream channels. Size distribution information for gravel was generally recorded only at trench locations. Any gravel values given are expressed as a percent of the total amount of less than 3.0-inch material present. The numeral zero is used to indicate a size fraction not observed, and the letter R is used to indicate the rare occurrence of a size fraction (one to four percent).

Gradation

Gradation information was recorded at trench locations only.

Maximum Particle Size

Maximum particle size is defined as the intermediate diameter length of the most frequently occurring clast present in a deposit (in centimeters). Erratic oversized materials (boulders, large cobbles) are generally not represented as the maximum particle size.

Particle Shape

Shape of clasts are classified into the following six categories.

- | | |
|------------------|---|
| Angular (ANG) | Particles have sharp edges and relatively plane sides with unpolished surfaces. |
| Sub-angular (SA) | Particles are similar to angular but have somewhat rounded edges. |
| Sub-rounded (SR) | Particles exhibit nearly plane sides but have well-rounded corners and edges. |
| Rounded (R) | Particles have smoothly curved sides and no edges. |
| Platey (P) | Particles are thin and flat with either rounded or nonrounded corners and edges. |
| Elongate (E) | Particles are several times longer than they are wide with rounded corners and edges. |

Remarks

This column is used to describe the general site location of petrographic field stations; location terms used include: surface, shallow wash, stream channel bank or bottom, borrow pit, and road cut. Surface indicates analysis was performed on top of the stated geologic unit. Shallow wash indicates analysis was performed on top of the unit but at the bottom of a small swale. Stream channel bank or bottom indicates analysis was performed in an exposed section (incision) or within a minor stream channel deposit, respectively.

APPENDIX C
TRENCH LOGS

EXPLANATION OF TRENCH LOGS

Trench logs were completed for excavated trenches. Each log presented in this appendix is chosen from a group of trench logs so that it represents the general aggregate conditions and properties of that entire group. Occasionally, the full compliment of trenches in a group was not excavated due to low gravel percentages and/or advanced caliche development found in the first one or two trenches of that group. Detailed explanations of the trench logs headings are as follows:

<u>COLUMN HEADING</u>	<u>EXPLANATION</u>
BULK SAMPLE	Representative samples were obtained by channel sampling a trench wall. Overburden and, in some trenches, dense caliche layers were avoided during the sampling procedure.
II -	100 lb. sample (2 bags) for road-base aggregate testing.
III -	400 lb. sample (55 gallon barrel) for concrete aggregate testing.
DEPTH	Depth corresponds to depth below ground surface in meters and feet.
LITHOLOGY	Graphic representation of soil types present in excavation.
USCS	Unified Soil Classification System symbols. For detailed information see Table F-1.
CONSISTENCY	The consistency of the in-situ deposit was estimated by visual observation of the soil in the trench walls, ease (or difficulty) of excavation of the trench, and trench-wall stability.
	Consistency descriptions of coarse-grained soils (GW, GP, GM, GC, SW, SP, SM, SC) are as follows:

DESCRIPTIONVery Loose (VL)

Will not hold vertical cut (when dry).

<u>Loose (L)</u>	Will hold vertical cut, but caves if disturbed.
<u>Medium Dense (MD)</u>	Holds vertical cut, even when disturbed; easily excavated.
<u>Dense (D)</u>	Holds vertical cut, difficult to excavate.
<u>Very Dense (VD)</u>	Very difficult to impossible to excavate.

SOIL DESCRIPTION

Except in cases where samples were classified based on laboratory data, the descriptions are based on visual classification. The procedures outlined in ASTM D 2487-69, Classification of Soils for Engineering Purposes and D 2488-69, Description of Soils (Visual-Manual Procedure) were followed. Solid lines across the column indicate known changes in the strata at the depth shown.

Definitions of some of the terms and criteria used to describe soils and conditions encountered during the excavation follow:

<u>Descriptive Name</u>	Name of soil, as determined by USCS, preceded by an adjective indicating the size range of the most abundant secondary material present.
<u>Particle Size</u>	For coarse-grained soils (sands and gravels) the size range of the particles visible to the unaided eye was estimated as fine, medium, coarse, or a combined range (e.g., fine to medium). These terms approximately correspond to the following sieve sizes: Gravel Fine No. 4 to 0.75-inch sieve Coarse 0.75-inch to 3-inch sieve Sand Fine No. 200 to No. 40 sieve Medium No. 40 to No. 10 sieve Coarse No. 10 to No. 4 sieve
<u>Particle Shape</u>	See Appendix B explanation pages.
<u>Gradation</u>	Gradations listed are those determined from percent amounts of boulders, cobbles, and gravel present. Descriptive terms used include: poor and well.

<u>Poor(ly)</u>	Predominantly one size or a range of sizes, with some intermediate sizes missing.
<u>Well</u>	Wide range in grain sizes present, with substantial amounts of most intermediate sizes.
<u>Secondary Material</u>	Percentage present by dry weight. Trace 5-12 percent Little 13-20 percent Some > 20 percent (e.g., <u>Some</u> slightly plastic <u>silt</u>)
<u>Plasticity of Fines</u>	See Appendix A explanation pages
<u>HCL Reaction</u>	As an aid for identifying calcium carbonate coatings and cementation, soil samples were tested in the field for their reaction to dilute hydrochloric acid. The intensity of the HCL reaction was described as none, weak, or strong.
<u>Caliche</u>	Caliche is a term applied to calcareous material of secondary accumulation. In this study, the definition includes both the soluble calcium (and other) salts and the clastic material (gravel, sand, silt or clay) in which the salts exist. See Table F-2 for a description of the stages of caliche development.
<u>Cobbles and Boulders</u>	See Appendix A explanation pages.
<u>Lithology</u>	The various rock types found in an excavated deposit are listed in order of decreasing abundance.
<u>Remarks</u>	This column was provided for comments regarding difficulty of excavation, caliche development, and backhoe refusal. Refusal indicates the inability of a JCB 3DIII backhoe (Case 680 equivalent) with a 2-foot wide bucket to excavate a trench to completion.

SIEVE ANALYSIS

The numbers cited represent the percentage by dry weight of each of the following soil components.

- GR Coarse aggregate particles that pass a 3-inch (75 mm) sieve but are predominantly retained on a No. 4 (4.75 mm) sieve.
- SA Fine aggregate particles that almost entirely pass a No. 4 sieve but are predominantly retained on a No. 200 (0.075 mm) sieve.
- FI Soil particles that pass a No. 200 sieve (silt and clay).

All percentages shown on logs are the result of laboratory testing.

BMO/AFRC-MX

UNIFIED SOIL CLASSIFICATION SYSTEM

DIAGNOSTIC CARBONATE MORPHOLOGY

STAGE	GRAVELLY SOILS	NONGRAVELLY SOILS
I	Thin, discontinuous pebble coatings	Few filaments or faint coatings
II	Continuous pebble coatings, some interpebble fillings	Few to abundant nodules, flakes, filaments
III	Many interpebble fillings	Many nodules and internodular fillings
IV	Laminar horizon overlying plugged horizon	Laminar horizon overlying plugged horizon

Stages of development of a caliche profile with time. Stage I represents incipient carbonate accumulation, followed by continuous build-up of carbonate until, in Stage IV, the soil is completely plugged.

Reference: Gile, L.G. Peterson, F.F., and Grossman, R.B., 1985, The K horizon: A master horizon of carbonate accumulation: Soil Science, v. 99, p. 74-82.

TABLE F-2

U ARSA POTENTIAL AGGREGATE SOURCE SYMBOLS

ERTEC WESTEN GENERAL GEOLOGIC UNIT EXPLANATION

NOTE

Shown in regions where rock is exposed, the areally predominant (greater than 10 percent) rock type is indicated. In those areas where the rock types occur, the predominant rock type is shown followed by the subordinate rock type (e.g., S_{up} Ia). Rock may be subdivided into horizons (A).

	I	INTRUSIVE - UNDIFFERENTIATED: Rocks formed by solidification of a melt or partially molten mass.
GR	I₁	INTRUSIVE - PLUTONIC: Rocks formed by solidification of molten material beneath the surface (e.g., granite, granodiorite, diorite, gabbro).
Vu	I₂	EXTRUSIVE - INTERMEDIATE AND ACIDIC: Volcanic rocks of intermediate and acidic composition formed by solidification of molten material at or near the surface (e.g., rhyolite, latite, dacite, andesite).
Vb	I₃	EXTRUSIVE - BASIC: Volcanic rocks of basic composition generally formed by solidification of molten material at or near the surface (e.g., basalt).
Vu	I₄	EXTRUSIVE (PYROCLASTIC): Rocks formed by accumulation of volcanic ejecta (e.g., ash, tuff, welded tuff, agglomerate).
Su	S	SEDIMENTARY - UNDIFFERENTIATED: Rocks formed by accumulation of clastic sediments, organic sediments and/or chemically precipitated minerals.
Su, Qtz	S₁	BIOHERCINOUS AND SILICEOUS ROCKS: Composed of sand size particles (e.g., sandstone, arkose, breccia) or of crystalline silicates (e.g., sand, chert).
Ls, Do, Cau	S₂	CARBONATE ROCKS: Composed predominantly of calcium carbonate derived by chemical precipitation (e.g., limestone, dolomite, chert).
	S₃	ARGILLACEOUS ROCKS: Composed of clay and silt-sized particles (e.g., siltstone, shale, calcarenite).
	S₄	EVAPORITE ROCKS: Precipitated from solution as a result of evaporation (e.g., halite, gypsum, anhydrite, selenite).
Su	S₅	CLASTIC CLASTIC ROCKS: Composed of gravel-size or larger clasts (e.g., conglomerate, breccia).
Mu	M	METAMORPHIC - UNDIFFERENTIATED: Rocks formed through recrystallization in the solid state of preexisting rocks by heat and pressure.
Mu	M₁	COARSE GRAINED: Rocks formed by higher-grade regional metamorphism, either banded or granular (e.g., gneiss, granulite, amphibolite).
Mu	M₂	FINE GRAINED: Schistose rocks formed by lower grade regional metamorphism (e.g., schist, slate, phyllite).
Mu	M₃	DIAGENETIC: Rocks formed chiefly by contact metamorphism (e.g., hornfels, marble).
Qtz	M₄	HYDROTHERMAL: Rocks formed by metamorphism of highly siliceous rocks.
	A	WIND-FILL
	A₁	WIND-FILL DEPOSITS: Fill-in coarse-grained materials deposited principally by wind, water or gravity.
Aal	A₁	TOURMALINE FLUVIAL DEPOSITS: Older, modern stream channel and flood-plain deposits.
Au, Aal	A₂	TOURMALINE FLUVIAL DEPOSITS: Older, modern stream channel and flood-plain deposits in elevated terraces overlying older modern drainages.
Au	A₃	TOURMALINE DEPOSITS: Wind-blown deposits of sand occurring as either thin sheets (A ₃) or dunes (A ₃).
Aol	A₄	TOURMALINE DEPOSITS: Deposits occurring in modern active playas (A ₄) or in other inactive playas or older lake beds and abandoned shorelines associated with extinct lakes (A ₄).
Aaf	A₅	TOURMALINE FAN DEPOSITS: Alluvial deposits consisting of debris flow and water-laid alluvium near mountain fronts, grading into predominantly water-laid alluvium deposited in shifting distributary channels near the basin center. (Younger (A ₅) interbedded with older (A ₅) alluvial fans are differentiated by surface soil development, terrain conditions and present depositional drainage environments).
Au	A₆	BROAD NON-VEGETATIVE UNIT: Most areally extensive unit is listed first.
Aaf	A₇ (A₈)	PERMANENT UNIT UNDERLIES THIS VOLUME OF OVERLYING DEPOSIT UNIT.

TABLE F-3

APPENDIX G

CROSS REFERENCE FROM MAP
NUMBER TO VERIFICATION ACTIVITY

CROSS REFERENCE FROM MAP NUMBER
TO VERIFICATION ACTIVITY

Included in this appendix is one table that is presented to allow cross reference to be made from this aggregate resources study to an appropriate verification study. Map numbers in the number series 400 to 599 on Drawing 1 are keyed to the published Verification report of Delamar Valley, Nevada (FN-TR-27-DM-I and II). If detailed information is required from a verification activity, the following search procedure can be used: determine the location of the activity required on Drawing 1, note the map number, refer to that map number in Table G-1, read from that table the verification activity type and number, refer to the appropriate verification report for the data required.

MAP NUMBER	ACTIVITY LOCATION	MAP NUMBER	ACTIVITY LOCATION
400	GS - 27	422	P - 7

AGGREGATE CLASSIFICATION SYSTEM

BASIN-FILL AND ROCK SOURCES * * *

REGATES)

RB Ia  BASIN FILL
 ROCK

BASIN-FILL OR ROCK SOURCES CONTAINING MATERIALS SUITABLE FOR USE AS ROAD-BASE AGGREGATES; BASED ON ACCEPTABLE LABORATORY AGGREGATE TEST RESULTS.

RB Ib  BASIN FILL

BASIN-FILL SOURCES CONTAINING MATERIALS SUITABLE FOR USE AS ROAD-BASE AGGREGATES; BASED ON CORRELATION WITH CLASS RB Ia SOURCE AREAS.

RB II  BASIN FILL

POTENTIAL BASIN-FILL SOURCES OF MATERIALS SUITABLE FOR USE AS ROAD-BASE AGGREGATES; BASED ON PHOTOGEOLOGIC INTERPRETATIONS, FIELD OBSERVATIONS, AND LIMITED OR INCONCLUSIVE ANALYSIS AND/OR ABRASION DATA.

UNSUITABLE SOURCES OF BASIN-FILL MATERIAL THAT MAY LOCALLY CONTAIN POTENTIALLY SUITABLE SOURCES OF AGGREGATES OF LIMITED QUANTITY

EXPLANATION

ATIONS

AGGREGATE CLASSIFICATION SYSTEM

BASIN-FILL AND ROCK SOURCES***

REGATES)

CA1

BASIN FILL
ROCK

BASIN-FILL OR ROCK SOURCES CONTAINING AGGREGATES THAT PRODUCED TRIAL MIX CONCRETE WITH 28-DAY COMPRESSIVE STRENGTHS EQUAL TO OR GREATER THAN 6500 PSI.

CA2

BASIN FILL
ROCK

BASIN-FILL OR ROCK SOURCES CONTAINING AGGREGATES THAT PRODUCED TRIAL MIX CONCRETE WITH 28-DAY COMPRESSIVE STRENGTHS LESS THAN 6500 PSI.

CB

BASIN FILL
ROCK

BASIN-FILL OR ROCK SOURCES CONTAINING AGGREGATES POTENTIALLY SUITABLE FOR USE IN CONCRETE; BASED ON ACCEPTABLE LABORATORY AGGREGATE TEST RESULTS.

CC1

BASIN FILL
ROCK

BASIN-FILL OR ROCK SOURCES CONTAINING AGGREGATES POTENTIALLY SUITABLE FOR USE IN CONCRETE; BASED ON CORRELATION WITH CLASS CA1 OR CA2 SOURCE AREAS.

ILL

REGATES)

CC2

BASIN FILL

BASIN-FILL SOURCES CONTAINING AGGREGATES POTENTIALLY SUITABLE FOR USE IN CONCRETE; BASED ON CORRELATION WITH CLASS CB SOURCE AREAS.

BASIN-FILL SOURCES CONTAINING FINE AGGREGATES USED WITH CRUSHED-ROCK SAMPLES FOR CERTAIN CONCRETE TRIAL MIXES.

UNSUITABLE SOURCES OF BASIN-FILL MATERIALS THAT MAY LOCALLY CONTAIN POTENTIALLY SUITABLE SOURCES OF AGGREGATES OF LIMITED EXTENT. UNTESTED SOURCES OF ROCK MATERIALS THAT MAY CONTAIN POTENTIALLY SUITABLE CRUSHED-ROCK AGGREGATES (SEE TEXT FOR ADDITIONAL INFORMATION)
