ABSTRACT

A system of data acquisition and reduction programs, TXCO is described. The programs were written for the transonic compressor test facility at the NPS Turbopropulsion Laboratory which is served by an HP1000 series computer operating under RTE-IVB. However, the structure of the program system (strict separation of acquisition and reduction, store raw data as acquired, routines to verify the data system, etc.) is of more general interest, and allows the system to be applied to any test rig. The introduction of a "program control array" accelerates execution and provides means for communication between programs, which otherwise execute individually.

ACKNOWLEDGMENT

This study was made possible by Professor Ray Shreeve, Director of the Turbopropulsion Laboratory (TPL) of the Department of Aeronautics, and by Professor Dr. Ing Heinz Gallus, Institute for Aero Engines and Turbomachines of the Technical University Aachen, West Germany; to both I express my thanks. Jim Hammer, the TPL Laboratory Manager, contributed to this program system by letting me share his brilliant knowledge and vast experience in the areas of instrumentation and turbomachines.

TABLE OF CONTENTS

1. INTRODUCTION

This report describes a system of data acquisition and reduction programs, designed to acquire data from the Turbopropulsion Laboratory's transonic compressor test facility. The computer hardware consists of an HP21MX mini computer with various peripheral devices. Both steady-state and high speed data are required to be taken as scheduled during a compressor test. The entire hardware configuration is shown in Fig. 1.

At the outset, the system of computer programs was required to do the following:

(i) Control via the "Interface Bus", measurement devices such as Scanivalves (S/V's), Scanivalve controllers, scanners, digital voltmeters (DVM), digital counters, analog to digital converters, and the acquisition timing device called PACER.

(ii) Perform data acquisition as efficiently as possible, store data in disc files, and document the test conditions.

(iii) Provide a means to check the data system (e.g., SUBROUTINE CHECK, Section 6.2).

(iv) Provide a means to verify the raw data (e.g., SUBROUTINE PICTR, called from SUBROUTINE PACER, Section 4.5. PICTR uses the auxiliary terminal to display the acquired wave form).

(v) Provide a means for the operator to communicate interactively. Since the operator at the system console is usually the investigator or research engineer and not a computer specialist, the program flow and the programmed interactive messages were required to be clear, logical and easy to understand.

The demand to speed up the data acquisition conflicted with the requirement of keeping the dialogue between program and operator clear. Interactive programs necessarily have extensive input-output operations which slow down the execution of the program. A reasonable compromise between these two choices was the introduction of a "program control array", CNTRL, whose elements - once pre-assigned - relieved the operator from entering routine decisions (e.g., telling the subroutines FREER and PACER how many Kulite signals are to be recorded and where to locate them; see Appendix A3: CNTRL(23Ø) through CNTRL(246)). Additionally the control array provides accounting data (e.g., the sequential number for raw data files).

In the present report complete documentation is given of the program system "TXCO". The system consists of a "father" program, TXCOØ, which, in operation, calls on a series of "son" programs TXCO1, TXCO2 or TXCO3.

The father program, TXCOØ, offers the investigator a menu of program branches to be scheduled according to a single digital entry as follows:

1.	Survey using the type 'A' and the type 'B' Kulite semiconductor pressure probes (Ref 1 and 2).	ABSRV
2.	On-line calibration type 'A' and type 'B' probe.	CALIB
3.	Acquisition of high speed data through the fast A/D converter, which is operated in free run mode.	FREER
4.	Acquisition of high speed data through the fast A/D converter, which now is controlled by a timing device, the PACER (Ref 3).	PACER
5.	Radial flow survey using a temperature-pneumatic four hole COMBINATION PROBE.	COMB
6.	Acquisition of all steady state data.	STDY
7.	Check the instrumentation.	CHECK
8.	Change the program control array.	CHNGE
9.	Reduce high speed data from the 'A' - 'B' probe system. REDAB uses the data gathered by ABSRV.	REDAB
10.	Reduce flow data from the combination probe. REDCO uses the data gathered by COMB.	REDCO
11.	Reduce steady state data and add this operating point to the compressor performance map. REDST uses the data gathered by STDY.	REDST

The investigator selects the desired program module by entering the appropriate number between 1 and 11. Entering 12 halts the program. Subroutines ABSRV, CALIB, FREER and PACER - they handle the high speed data - are contained in PROGRAM TXC01 (Section 4). Subroutines COMB and STDY - they handle the steady state data - are contained in PROGRAM TXC02 (Section 5). Subroutines CHECK and CHNGE - they are used by the operator to control the program flow and verify the data system - are contained in PROGRAM TXC03 (Section 6). After the select code is entered, and verified either by entering an additional parameter or tapping the RETURN key, the "father" program suspends its operation while the desired "son" program (TXC01, TXC02 or TXC03) executes. The entire TXCO-system works interactively with the operator and displays as many informative messages as possible.

The program descriptions in the following sections explain, in user-manual form, how to handle each subroutine. The descriptions often resemble each other, which in the interests of utility was deliberately not avoided. A compressor failure prevented the author from using the programs for compressor test runs. The report is therefore presented with only a very short section of conclusions and recommendations. The program system is not considered to have been perfected, since little experience has been gained with its operation other than in "dry" runs.

2. GUIDE TO THE PROGRAM DESCRIPTIONS

Detailed descriptions of the programs are given in the following sections. First, in Section 3, a flow chart and listing are given for the father program TXCOØ. Then, the descriptions given in Sections 4 through 6 (of TXCO1 through TXCO3) are structured as follows:

PROGRAM XXXX (or SUBROUTINE XXXX): PURPOSE:
A brief description of the purpose of this particular program module is given, and its capabilities and restrictions are noted.

ARGUMENTS: If the program module is a subroutine, which is called with parameters, the parameter list is explained.

EXTERNALS: The externals of each program module are listed. This information is necessary when loading the relocatable binary version (indicated by the % sign as first character of the disc file name under the RTE-IV operating system).

COMMON BLOCKS: The members of the COMMON blocks and their length in 32-bit words are listed and explained.

MNEMONIC ABBREVIATIONS: The mnemonic acronyms which each program module uses are listed and explained.

ERROR MESSAGES: If a salvageable error occurs during the execution of a program module, an error message with suggestions for how to resolve the problem are described.

PROCEDURE: This subsection, which should always be used together with the flow chart, describes how to go through the program module. Hints for how to utilize all program features are given.

DATA FILE: The date file name is explained for all program modules, which save data. The first two characters are typical for the type of data which the file contains; for example,

Data File Name	Type of Data	Created By
T1rrss	'A'-'B' probe survey	ABSRV
T2rrss	free run sample	FREER
T3rrss	paced run sample	PACER
T4rrss	all raw steady state data	STDY
T5rrss	combination probe survey	COMB

rr — # of test run

ss — sequential # of data file type

The following modules are synchronized through the data file:

Data Reduction Program		File Name		Data Acquisition Program
REDAB	↔	T1rrss	↔	ABSRV
REDST	↔	T4rrss	↔	STDY
REDCO	↔	T5rrss	↔	COMB

VARIABLES: All variables, their type (REAL or INTEGER) and length (only if the variable is used as an array), together with a brief description, are listed.

The flow chart and a FORTRAN-IV compiler listing of the program module complete each description.

The source codes of programs TXCOØ, TXCO1, TXCO2 and TXCO3 are available in the disc files &TXCOØ, &TXCO1, &TXCO2 and &TXCO3. Since TXCO1, TXCO2 and TXCO3 use common subroutines and functions, the latter are grouped together in file &TXCOU, where the "U" indicates the following "utility" program modules:

ACQN	Positions S/V and reads DVM.
CNTL	Closes scanner channel.
CURVE	Compute linear curve fit.
ICON	Converts two-digit INTEGER to ASCII-string.
IPORT	Interrogates S/V.
PICTR	Use CRT to display the acquired data.
REWRF	Data transfer disc ↔ array.
RPACE	Triggers A/D through PACER.
SCANR	Closes scanner channel and reads SVM, counter.
TIME	Gets date and time → ASCII-string.
WAIT	Causes a defined time delay.

When loading %TXCO1, %TXCO2 or %TXCO3, the relocatable binary utility file %TXCOU must also be loaded in order to satisfy the externals. The modules of TXCOU are described in Section 7, but in less detail than the programs in Sections 4 through 6.

4. PROGRAM TXCO1

4.1. DESCRIPTION

TXCO1 is a son program of the father program TXCOØ, by which it is scheduled, if one of the following operations is desired:

1 - A - B - probe system survey

2 - On line calibration, KULITE type 'A' and 'B' probes

3 - Acquisition of high speed data in free run mode

4 - Acquisition of high speed data in paced run mode.

When scheduled by TXCOØ, which suspends operation while the son program TXCO1 executes, the program TXCO1, reads the program control array from the disc, sets the HP interface bus and the measurement and control devices to remote control and programs the Digital Voltmeter (DVM), the scanners and the counter. CNTRL (50) is the actual decision variable to select and call the subroutine, which performs the desired operation. When this subroutine has terminated, the interface bus and the devices are released from remote control and the control array is written into a disc file, so that the next TXCO module can read it. The correct termination of each subroutine can be verified by checking the stop codes. Note, that each stop coding ending on 77 indicates correct execution of a subroutine.

CNTRL (50)	Subroutine	STOP Code
1	ABSRV	TXCO1 : STOP 0177
2	CALIB	TXCO1 : STOP 0277
3	FREER	TXCO1 : STOP 0377
4	PACER	TXCO1 : STOP 0477

Any other STOP code indicates an error and utilizing a program list the operator can trace the problem. The first two digits of the STOP code are typical for the subroutines. An example: the program stops at STOP code 0304; the first two digits read 3 and this tells the operator that it was subroutine FREER which ran into trouble, because the ending two digits read 04, which is different from 77; a program list uncovers that the failure occurred while writing into a disc file using FMP (File Management Package) subroutine WRITF near line 1005. STOP codes are crucial for a complex program system in order to rapidly detect and salvage problems, even during a test run.

EXTERNALS: REWRF, ABRT, RMOTE, ABSRV, CALIB, FREER, PACER, CLEAR, LOCL

COMMON BLOCKS: CONTR, CIBUF, FMP

FORTRAN conventions for the HP21MX computer request COMMON blocks to be predefined in a BLOCK DATA subroutine prior to using a COMMON block in a program, subroutine or function.

BLOCK DATA subroutine	arrays & variables	length in words
CONTR	CNTRL	400B = 256
CIBUF	IBUF	3200B = 1664
FMP	IDCB,IFILE,ISIZE,ISECU,ICR	227B = 151

The COMMON block CONTR allocates the space for the control array CNTRL. A key to decode the individual elements of CNTRL can be found in the Appendix.COMMON block CNTRL is designed to take the largest raw data array - IBUF (1664) in subroutine

FREER - even if other subroutines only partially use the space, allocated by the block CIBUF. The arrays and variables allocated by the COMMON block FMP are frequently used for the data transfer from and to the disc. Since each individual subroutine saves the data prior to terminating, more than one subroutine or function may use the same buffer area.

MNEMONIC ABBREVIATIONS: None

ERROR MESSAGES: If CNTRL (50) is less than 1 or greater than 4, no subroutine can be selected and the program terminates, outputting an error message (FORMAT 102) to the terminal.

PROCEDURE: For more detailed information study the flow chart and the information given in the section PURPOSE.

DATA FILE: None

VARIABLES IN BLOCK DATA CONTR:

CNTRL (256)	integer	program control array.

VARIABLES IN BLOCK DATA CIBUF:

IBUF (1664)	integer	buffer array for the raw data.

VARIABLES IN BLOCK DATA FMP:

IDCB (144)	integer	data control block.
IFILE (3)	integer	array to contain file name.
ISIZE (2)	integer	array to contain # of records in the first and record length in 16-bit-words in the second word.

ISECU	integer	security code of data file.
ICR	integer	cartridge reference number, where data file is located.

VARIABLES IN PROGRAM TXC01:

CNTRL (256)	integer	program control array.
NOLF	integer	suppresses line feed.
LI	integer	LU3 of standard input device (terminal).
ISTOP	integer	control variable to select STOP code.
X1	real	dummy variables.
X2	real	
X3	real

4.2. SUBROUTINE ABSRV:

PURPOSE: Acquisition of high speed data from the 1-stage axial compressor using miniaturized probes equipped with KULITE semiconductor pressure transducers.

ARGUMENTS: None

EXTERNALS: CALIB, TIME, REAT, PURGE, OPEN, WRITE, POSNT, CLOSE, SCANR, PACER.

COMMON BLOCKS: CIBUF, CONTR, FMP. For detailed explanation refer to the TXCOl description.

MNENOMIC ABBREVIATIONS:

RE ... Repeat data acquisition of this yaw position.

NE ... Proceed to next yaw position.

EN ... End data acquisition at various yaw positions.

UP ... Update position readings of probes prior to data taking.

TA ... Initialisation command to take data.

PU ... Allow purge of an existing data file.

ERROR MESSAGES: If the number of yaw positions exceeds the previously defined number, the program terminates the subroutine correctly (in order to save the already acquired data) and displays an error message (FORMAT 118). The total # of possible yaw positions is input prior to creating the raw data file, so that latter can be created at the desired length.

PROCEDURE: For more detailed information, study the flow chart. After having read the accounting data, assigned the I/O references and preset the raw data array, ABSRV asks the operator, whether the 'A'-'B'- probe system has been calibrated on line. If the answer is NO, ABSRV calls the subroutine CALIB, which controls the calibration. Then the calibration results are entered and the operator is asked to input the number of different yaw positions. Based on this information a raw data file of the appropriate length will be created and positioned. If the file with the automatically determined name already exists, the operator either allows overwriting the existing file (Input : PU) or renames the current data file (Input : any alphabetic character other than T). Prior to taking data the position of the probes is scanned and displayed. This control loop can be repeated by keying UP. Inputting TA initializes the data acquisition by subroutine PACER. Upon completion of the scan the operator can repeat this scan (Input : RE), proceed to the next point (Input : NE) with a different yaw position of both 'A' and 'B' probe. If the operator accidentally has decided to proceed to a probe position beyond the previously specified number, ABSRV displays an error message and terminates the subroutine correctly, i.e. saves the data in file, closes the file and writes the accounting data back into the control array.

DATA FILE: For more detailed information, study the following flow chart. The default file name is Tlrrss (rr ... ASCII converted run #, ss ... ASCII converted sequential #).

VARIABLES:

IBUF (1664)	integer	buffer array
CNTRL (256)	integer	control array
IDCB (144)	integer	data control block, used for FMP calls
IFILE (3)	integer	array to contain current file name calls
ISIZE (2)	integer	specifies # of records and record length
ISECU	integer	security code of data file
JSECU	integer	ASCll-converted security code
ICR	integer	cartridge reference number, when data file is located
JCR	integer	ASCII converted cartridge reference number
POS (7)	real	array to contain probe positions
RBUF (62)	real	data array, set equivalent to IBUF
NOLE	integer	suppresses line feed
NOCR (2)	integer	suppresses line feed and carriage return
ICLR (3)	integer	clear line above cursor
IDCBS	integer	length of data control block IDCB
IPAGE	integer	count of current page
IDOC	integer	count of current program run
IDOCF	integer	count of current data file sequential #
IL	integer	number of words to be transferred in FMP calls

ITYPE	integer	type of data file
IFRST	integer	standard for the first two characters of file name
LI	integer	LU3 of standard input device (terminal)
LO	integer	LU# of standard output device (line position)
LS1	integer	LU# of scanner #1
LS2	integer	LU# of scanner #2
ICAL	integer	decision parameter
IDUM	integer	decision variable
SLOPEA	real	slope of linear curve fit for A probe calibration
SECONA	real	intercept of linear curve fit for A probe calibration
SLOPEB	real	slope of linear curve fit for B probe calibration
SECONB	real	intercept of linear curve fit for B probe calibration
AVRGEA	real	average voltage A probe, when aligned to flow
AVRGEB	real	average voltage B probe, when aligned to flow
PBARO	real	barometric pressure
NPOS	integer	number of different yaw positions 'A'-'B' survey
IERR	integer	error flag (FMP package)

IMON	integer	ASCII converted month of the year
IDAY	integer	ASCII converted day of the month
IHOUR	integer	ASCII converted hour of the day (24 hr clock)
IMIN	integer	ASCII converted minute of the hour
IYEAR	integer	ASCII converted last two digits of current year
IFRST	integer	temporary buffer variable
NEW	integer	scratch variable for change of file name
IPOS	integer	current yaw position count
IREC	integer	record positioning variable

4.3. SUBROUTINE CALIB

PURPOSE: Control the on-line calibration for the A-B- probe system. This includes data acquisition and storage as well as approximating the calibration results.

ARGUMENTS: None

EXTERNALS: TIME, FREER, PACER, CURVE

COMMON BLOCKS: CONTR. For detailed explanation refer to the TXCO1 description.

MNEMONIC ABBREVIATIONS:

RE ... Repeat this point

EN ... End the on-line probe calibrations

ERROR MESSAGES: If no calibration is performed, the subroutine outputs a warning (FORMAT 108) and terminates; this can happen, if at the first decision to be made the operator inputs EN.
If less than two points with different reference pressures are taken, the subroutine outputs an error message (FORMAT log) and terminates.
Both messages, if studied carefully, tell the operator how to avoid mistakes.

PROCEDURE: For more detailed information, study the flow chart. After having read the accounting data and assigned the I/O references, CALIB asks the operator to input a

number (which, when the program was debugged, was the digital multimeter read-out displaying the analog voltage of either 'A' or 'B' probe). This input initializes the data acquisition at the first reference pressure. Then the program reminds the operator to switch the pacer to free run mode. The operator responds by pressing the return key and the program calls subroutine FREER. Average voltage from both 'A' and 'B' probe, together with the KULITE reference pressure are written into the arrays AVOLT, BVOLT and RPRES, respectively. The operator then decides whether to repeat the measurements at this reference pressure (Input : RE), end the calibration (Input : EN) or proceed to the next point (Input : any numerical value). If the calibration is to be terminated, the operator is reminded to switch the pacer to paced run mode and, with the reference pressure unchanged, a paced scan is taken from both 'A' and 'B' probe (using PACER). Then subroutine CURVE computes an average linear curve fit through the data points (AVOLT vs. RPRES and BVOLT vs. RPRES respectively). In both cases slope and intercept are printed. Note, that the intercept is meaningless, but required in subroutine CURVE, which uses a least squares algorithm. CALIB then terminates and writes the accounting data back into the control array.

DATA FILE: Handled by subroutines FREER (Section 4.4) and PACER (Section 4.5).

VARIABLES:

CNTRL (256)	integer	control array
AVOLT (10)	real	array to contain average voltages from A probe
BVOLT (10)	real	array to contain average voltages from B probe
RPRES (10)	real	array to contain reference pressures
DMM (10)	real	array to contain additional data (e.g.: DMM read outs)
NOLF	integer	suppresses line Feed
NOCR (2)	integer	suppresses line Feed and carriage return
ICLR (3)	integer	clears line above cursor
ITIME (5)	integer	array to contain ASCII converted date and time
IO (5)	integer	scratch array
IPAGE	integer	count of current page
LI	integer	LU# of standard input device (terminal)
LO	integer	LU# of standard output device (line printer)
IMON	integer	ASCII converted month of the year
IDAY	integer	ASCII converted day of the month
IYEAR	integer	ASCII converted last two digits
IHOUR	integer	ASCII converted hour of the day (24 hr clock)

IMIN	integer	ASCII converted minute of the hour
IPTS	integer	variable count total # of calibration positions
IPREV	integer	variable temporary stores contents of CNTRL (219)
IDUM	integer	scratch variable
DM	real	variable used to decode value from array IO
IREC	integer	starting record for paced run-data array
SLOPE	real	slope of linear curve fits
SECON	real	intercept of linear curve fit (as from CURVE)

4.4. SUBROUTINE FREER:

PURPOSE: Control data acquisition from HP 5610 A/D converter, store data in file and documentation, perform calculation of average voltage.

ARGUMENTS: AVOLT, BVOLT, PREFR

AVOLT	real	average voltage from 'A'- probe, based on NRPT3 points
BVOLT	real	average voltage from 'B'- probe, based on NRPT3 points
PREFR	real	reference pressure for KULITE transducers (raw data format)

EXTERNALS: TIME, ICON, SCANR, EXEC, ABREG, CREAT, OPEN, PURGE, WRITF, CLOSE

COMMON BLOCKS: CIBUF, CONTR, FMP. For detailed description refer to the TXC01 description

MNEMONIC ABBREVIATIONS:

PU ... Allow purge of an existing data file

ERROR MESSAGES: If the EXEC call to read the voltages from the A/D converter is not executed correctly, an error return occurs as follows:

```
                               ┌──▷ set the no-abort bit.

      GO TO 20                           subroutine
```

PROCEDURE: For more detailed information, study the flow chart. The subroutine reads the accounting data from the control array and defines FMP parameters (FMP : File Management Package, manipulates disc Files). Next the I/O references are assigned and all words of the raw data array are preset to be 177777B. If CNTRL (37) is set to 1, the heading for the Free Run documentation page is printed. If CNTRL (38) is set to one, a key to the printout is printed. Then the data acquisition loop starts and executes NRPT1 times (NRPT1 = CNTRL (230) = number of KULITE signals to be acquired; maximum is 16). Should the sequential number for the data file name become greater than 99, the first two characters of the file name are changed from T2 (default) to S2 and the count is reset to zero. Additional data is acquired and the probe positions are read and written into the variable IOX1M. Prior to the data acquisition all unused elements of the data array are set to zero. Utilizing the EXEC call NRP2 measurements are performed and the A/D digital

output is written into array IBUF, starting at address of word IBUF (1). ICHNL specifies the selected A/D analog input channel. The 4 in the parameter list causes the A/D converter to dump data into the CPU as fast as possible via DMA (Direct Memory Access). If an error occurs, its reason is enquired (see preceding segment ERROR MESSAGES). To calculate the average voltage, all words of IBUF must be anded with IMASK, because bits 0 through 5 are used to control the data transfer.

```
          bit  15   12     9     6     3     0
IBUF(J2)       1 1 1 1 0 0 1 0 1 1 1 0 0 0 1 0  =  171342B
IMASK          1 1 1 1 1 1 1 1 1 1 0 0 0 0 0 0  =  177700B = -64
IBUF(J2) = IAND (IBUF(J2), IMASK)
IBUF(J2) =     1 1 1 1 0 0 1 0 1 1 0 0 0 0 0 0  =  171300B = -3392
```

To derive the voltage, IBUF(J2) must first be divided by the maximum value which can be transferred by a 16-bit word when the bits 0 through 5 do not contain data; this word is

```
               0 1 1 1 1 1 1 1 1 1 0 0 0 0 0 0  =  077700B = 32704
```

This bit configuration corresponds to the full scale voltage (FSVLT) of +1 Volt. When no bit is set, the voltage is 0 (ensured by calibration). Thus if the integer, IBUF(J2) is divided by 32 704 and multiplied by unity the voltage is obtained. Since the bits 0 through 5 are not used for data, the maximum voltage resolution of the A/D converter is

$$R = \frac{100B}{77700B} * FSVLT = \frac{64}{32\ 704} * FSVLT = \frac{1}{511} * FSVLT$$

$$R = .001\ 956\ 947\ Volt, \text{ if } FSVLT = +1.0\ V$$

The voltage associated with the bit configuration

1 1 1 1 0 0 1 0 1 1 0 0 0 0 0 0 = 171300B = -3392

is -.103 718 Volt = $\frac{-3\ 392}{32\ 704}$ * 1.0 Volt. In the Subroutine, however, the division through 32 704 and the multiplication with FSVLT is executed after all the voltages from NRPT2 points are added in order to compute the average voltage. The average voltage then is written into the variable AVOLT or BVOLT, depending on which probe has been selected. The data then are saved in a file. If a file with the automatically determined name already exists, the operator either allows overwriting the existing file (Input : PU) or renames the current data file (Input : any alphabetic character other than T). This is the only interactive manipulation in the subroutine. The data acquisition loop terminates, printing the most important data. Accounting data are written back into the control array and the subroutine returns control to the calling program.

DATA FILE: The data file consist of 13 records with a length of 128 words each, so that 1664 = (128 * 13) words can be stored. The default file name is T2rrss (rr ... ASCII converted run #, ss ... ASCII converted sequential #).

VARIABLES:

IBUF (1664)	integer	buffer array for raw data
CNTRL (256)	integer	control array
IDCB (144)	integer	data control block, used for FMB calls

IFILE (3)	integer	array to contain current file name
ISIZE (2)	integer	specifies # of records and record length
ISECU	integer	security code of data file
ICR	integer	cartridge reference number, where data file is located
NOLF	integer	suppresses line feed
NOCR (2)	integer	suppresses line feed and carriage return
ICLR (3)	integer	clear line above cursor
IOXIM (9)	integer	array, where 'A' and 'B' probe positions are written into in ASCII code
FSVLT	real	full scale voltage of A/D converter
IDCBS	integer	length of data control block IDCB
IPAGE	integer	counts of current page
IDOC	integer	counts, how often this subroutine is called
IDOCF	integer	count of current data file sequential #
ITYPE	integer	type of data file
IFRST	integer	standard for the first two characters of file name
ISP	integer	decision variable, used to space the output

IL	integer	number of words to be transferred in FMP calls
LI	integer	LU# of standard input device (terminal)
LO	integer	LU# of standard output device (line printer)
LS1	integer	LU# of scanner #1
LS2	integer	LU# of scanner #2
ISV1	integer	code # of S/V controller #1
ISV4	integer	code # of S/V controller #2
NRPT1	integer	# of various KULITE signals to be acquired
NRPT2	integer	total # of point, taken from each KULITE signal
NRPT3	integer	= NRPT2+ : DO loop start address
IMASK	integer	masking variable
IW	integer	controls time delay between closing S/V port and reading voltage
IMON	integer	ASCII converted month of the year
IDAY	integer	ASCII converted day of the month
IHOUR	integer	ASCII converted hour of the day (24 hr clock)
IMIN	integer	ASCII converted minute of the hour
IYEAR	integer	ASCII converted last two digits of current year
ICHNL	integer	A/D input channel to be selected
FREQ	real	RPM of the transonic compressor

CIM	real	immersion of the combination probe
CYAW	real	yaw angle of the combination probe
PREF	real	KULITE reference pressure
PREFR	real	KULITE reference pressure as returned to the calling routine (either CALIB, ABSRV or TXCO1)
P1	real	pressures P_1, P_{23} & P_4 from calibration probe
P23	real	
P4	real	
E	real	Temperature reading from sensor ahead of rotor (in mV)
DE	real	Differential temperature reading from station ahead of rotor across rotor
XIM	real	Immersion of the KULITE probe
YAW	real	Yaw angle of the KULITE probe
IA	integer	Variable to contain contents of A register
IB	integer	Variable to contain contents of B register
AVRGE	real	KULITE output average voltage after amplification and A/D conversion
AVOLT	real	'A' probe output average voltage
BVOLT	real	'B' probe output average voltage
ISP	integer	control variable to space output
IDUM	integer	decision variable

IERR	integer	error flag returned from FMP calls
JSECU	integer	ASCII converted security code
JCR	integer	ASCII converted cartridge reference number
NEW	integer	variable to contain changed first two characters of raw data file name

Terminate subroutine; write accounting data back into control array
RETURN

4.5. SUBROUTINE PACER:

PURPOSE: Control data acquisition from HP 5640 A/D converter if this device is triggered by the pacer, store data in file and document all steps.

ARGUMENTS: IREC

IREC integer starting record #, where raw KULITE and additional data are written

EXTERNALS: TIME, ICON, SCANR, ACQN, RPACE, PICTR, CREAT, OPEN, PURGE, WRITF, CLOSE

COMMON BLOCKS: CIBUF, CONTR, FMP. For detailed description refer to the TXC01 description.

MNEMONIC ABBREVIATIONS:

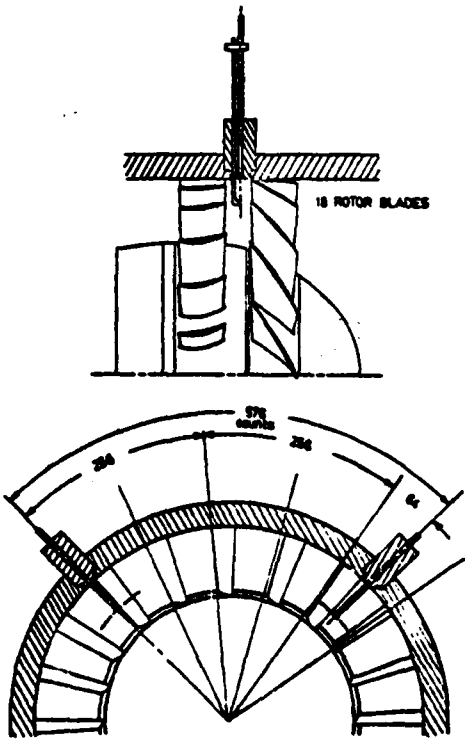
PU ... Allow purge of an existing data file

RE ... Repeat data acquisition

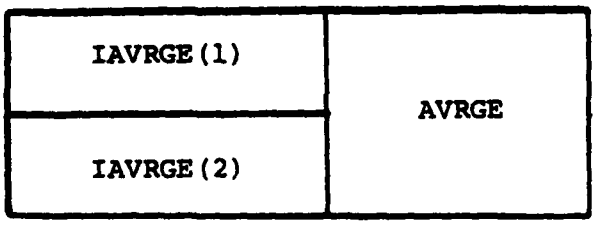
ERROR MESSAGES: None

PROCEDURE: For more detailed information, study the flow chart! The subroutine reads the accounting data from the control array and defines FMP parameters (FMP: file management package, manipulates disc files; refer to the HP manuals for more information). Next the I/O references are assigned and the words of the data array are present. If CNTRL (37) is set to 1, the heading for the paced run documentation page is printed. If CNTRL (38) is set to 1, a key to the print

out is printed. Then the data acquisition loop starts and executes NRPT1 times (NRPT1 = CNTRL (230) = number of KULITE signals to be acquired; maximum is 16). If CNTRL (39) is set to 1 (i.e.: subroutine PACER is called from subroutine ABSRV, which takes care of creating/opening, positioning and closing files), the accounting of the data file names is skipped. If otherwise, i.e. CNTRL (39) is not equal to 1, the sequential number for the data file name exceeds 99, the first two characters of the file name are changed from T3 (default) to S3 and the count is reset to zero. Additional data is acquired and the probe positions are read and written into the variable IOX1M. Since the KULITE probes are mounted in physically different positions (the phase angle is 90°, i.e. $2\frac{1}{4}$ times 40°, where 40° is double the rotor inter-blade angle), and the signals must be converted from the same point in the rotor blade wake, the IBLADE for the 'B' probe has to be increased by the appropriate amount, which is 576 (see sketch).



The operator is then informed that the system is ready for the next data scan. Depressing the RETURN key starts the data acquisition. Pacer mode (1 or 2), selected blade pair, increment to step through the 256 blade passage locations and the number of measurement repetitions at each location (i.e. at each IBLADE) are read from the control array. If the pacer is operated in mode 2 (i.e. selects a specific blade pair), the bit 15 is set by adding IADD = 100000B to the start and stop address. Refer to the RPACE description for details concerning how the data acquisition is performed. Not only the voltages, through subroutine RPACE, but also additional data are written into the raw data array. Some of the data are multiplied by 1,000,000 in order to be able to store all valid digits in integer constants and the average voltage AVRBE is set equivalent to the array IAVERGE(2) by an EQUIVALENCE statement.



Date and time are written into the raw data array also. If CNTRL(40) is set to 1, the wave as acquired is displayed on the terminal, which is selected by its logical unit number LA. Refer to the detailed description of subroutine PICTR for further information on how this is achieved; i.e. to use a non-graphics

terminal for plotting. The resolution of the terminal plot is is very limited. The option to display the just-acquired periodic high speed signal is designed to give the operator an opportunity to immediately verify the correctness of the data acquisition. Connecting a lead from KULITE amplifier output to an oscilloscope gives the investigator the chance to check digitized data against original analog data. If an error is encountered, the data scan may be repeated (Input : ... RE). Depressing the RETURN key causes the subroutine to proceed to the next task, the storing of the data. File name, ASCII converted security code and ASCII converted cartridge reference number are written into the raw data array. The raw data file is either created/opened and closed by subroutine PACER (CNTRL (39) is not equal 1) or this subroutine is called from subroutine ABSRV, which already has created/opened and positioned the raw data file and will close it (CNTRL (39) is set to 1). If, in the first mode, the automatically determined file name already exists, the operator either allows overwriting the existing file (Input: PU) or renames the current data file name (Input: any alphabetic character other than T). The starting record number is also written in the data array. If CNTRL (39) is not equal 1, the raw data file is closed and the data acquisition loop stops printing all the additional data on the documentation page. The accounting data are written back into the control array and the subroutine terminates.

DATA FILE: For more detailed information, study the key to the raw data file following this description. The default file name is T3rrss (rr ... ASCII converted run #, ss ... ASCII converted sequential #).

VARIABLES:

IBUF (1664)	integer	buffer array
CNTRL (256)	integer	control array
IDCB (144)	integer	data control block; used for FMP calls
IFILE (3)	integer	array to contain current file name
ISIZE (2)	integer	specifies # of records and record length in words
ISECU	integer	security code of data file
JSECU	integer	ASCII converted security code
ICR	integer	cartridge reference number, where data file is located
JCR	integer	ASCII converted cartridge reference number
NOLF	integer	suppresses line feed on terminal
NOCR (2)	integer	suppresses line feed and carriage return on terminal
ICLR (3)	integer	clear line above cursor
IBUF1 (384)	integer	raw data array, set equivalent to IBUF
IOXIM (9)	integer	array to contain probe positions in ASCII code

IAVRGE (2)	integer	array to contain average voltage, set equivalent to AVRGE
IDCBS	integer	length of data control block IDCB in words (here : 144)
IPAGE	integer	count of current page
IDOC	integer	count of current program run
IDOCF	integer	count of current data file sequential #
IL	integer	number of words to be transferred in FMP calls
ITYPE	integer	type of data file (here: 1)
IFRST	integer	standard for the first two characters of data file name
ISP	integer	control variable, used to space the output
LI	integer	LU# of standard input device (system console)
LO	integer	LU# of standard output device (line printer)
LA	integer	LU# of auxiliary output device (auxiliary terminal)
LS1	integer	LU# of scanner 1
LS2	integer	LU# of scanner 2
ISV1	integer	number of S/V controller 1
ISV4	integer	number of S/V controller 2
NRPT1	integer	number of KULITE measurements ('A', 'B', case KULITES)

IW	integer	time delay between closing S/V part and reading transducer voltage From DVM
IMON	integer	ASCII converted month of the year
IDAY	integer	ASCII converted day of the month
IYEAR	integer	ASCII converted last two digits of current year
FREQ	real	RPM of the compressor
CIM	real	immersion of the combination probe
CYAW	real	yaw angle of the combination probe
PREF	real	reference pressure for the KULITE probes
P1	real	pressure P_1 from the combination probe
P23	real	pressure P_{23} from the combination probe
P4	real	pressure P_4 from the combination probe
E	real	thermocouple output, Station '0'
DE	real	thermocouple differential output from '0' across rotor
XIM	real	immersion of either 'A'- or 'B' probe
YAW	real	yaw angle of either 'A'- or 'B' probe
IADD	integer	variable to be added to start and stop address for paced run to

		compensate phase angle between these probes
IDUM	integer	decision variable
IPAMO	integer	pacer mode (1 or 2)
IPAIR	integer	selected blade pair
ISTART	integer	start address for paced run
ISTOP	integer	stop address for paced run
INCR	integer	increment for paced run
IRPT	integer	number of repetitions at each IBLADE
J111	integer	dummy variable
J222	integer	dummy variable
DUM	real	dummy variable
IERR	integer	error flag used by FMP calls
NEW	integer	scratch variable used to change file name

5. PROGRAM TXCO2

5.1. DESCRIPTION

TXCO2 is a son program of the father program TXCOØ, by which it is scheduled if one of the following operations is desired:

5 - Radial survey using the combination probe

6 - Scan through all steady state data

When scheduled by TXCOØ, which suspends operation while the son program TXCO2 executes, the program TXCO2 reads the program control array from the disc, sets the HP interface bus and the measurement and control devices to remote control and programs the digital voltmeter (DVM), the scanners and the counter. CNTRL(50) is the actual decision variable to select and call the subroutine, which performs the desired operation. When this subroutine has terminated, the interface bus and the devices are released from remote control and the control array is written into a disc file, so that the next TXCO module can read it. The correct termination of each subroutine can be verified by checking the stop codes. Note that each stop code ending in 77 indicates correct execution of a subroutine.

CNTRL(50)	Subroutine	STOP Code
5	COMB	TXCO2 : STOP 0577
6	STDY	TXCO2 : STOP 0677

Any other STOP code indicates a mistake and with the help of a program list the operator can trace the problem. The first two digits of the STOP code identify the subroutine. An example: if the program stops at STOP code 0604, the first

two digits read 6 and tells the operator that it was subroutine STDY which encountered problems. The last two digits read 04 (no error would give 77). A program list reveals that the failure occurred after attempting to purge an existing data file using FMP (File Management Package) subroutine PURGE near line 752. Maybe the cartridge, where the raw data are directed, has not been mounted with the MC-command from FMGR. STOP codes are crucial to a complex program system in order to rapidly detect and salvage problems, even during a test run.

EXTERNALS: REWRF, ABERT, RMOTE, COMB, STDY, CLEAR, LOCL

COMMON BLOCKS: FMP, CIBUF, CONTR

FORTRAN conventions for the HP 21 MX computer request COMMON blocks to be predefined in a BLOCK DATA subroutine prior to using a COMMON block in a program, subroutine or function.

BLOCK DATA Subroutine	Arrays & Variables	Length in Words
FMP	IDCB,IFILE,ISIZE,ISECIA,ICR	$227B = 151_{10}$
CIBUF	IBUF	3200B = 1664
CONTR	CNTRL	400B = 256

The arrays and variables allocated by the COMMON block FMP are frequently used for the data transfer from and to the disc. COMMON block CIBUF is designed to take the largest raw data array in the TXCO data acquisition and reduction system - IBUF(1664) in subroutine FREER. The largest data array in TXCO2 is PDAT (24, 21) with 1008 = 2*21*24 words. The TXCO2 subroutines only partially use the COMMON area. The COMMON

block CONTR allocates the space for the control array CNTRL. Since each individual subroutine saves the data prior to terminating, the buffer area for the raw data can be shared by more than one subroutine or function.

MNEMONIC ABBREVIATIONS: None

ERROR MESSAGES: If CNTRL(50) is less than 5 or greater than 6, no subroutine can be selected and the program terminates outputting an error message (FORMAT 102) to the standard input device; i.e. the terminal.

PROCEDURE: For more detailed information study the flow chart and the information given in the subroutine descriptions.

DATA FILE: None

VARIABLES IN BLOCK DATA FMP:

IDCB (144)	integer	data control block
IFILE (3)	integer	array to contain file name
ISIZE (2)	integer	array to contain # of records in the first and record length in the second 16-bit word
ISECU	integer	security code of data file
ICR	integer	cartridge reference number, where data file is located

VARIABLES IN BLOCK DATA CIBUF:

IBUF (1664)	integer	buffer array for the raw data

VARIABLES IN BLOCK DATA CONTR:

CNTRL (256)	integer	program control array

VARIABLES IN PROGRAM TXCO2:

CNTRL (256)	integer	program control array
NOLF	integer	suppresses line feed
LI	integer	LU# of standard input device (terminal)
ISTOP	integer	control variable to select STOP code

FLOW CHART PROGRAM TXCO2:

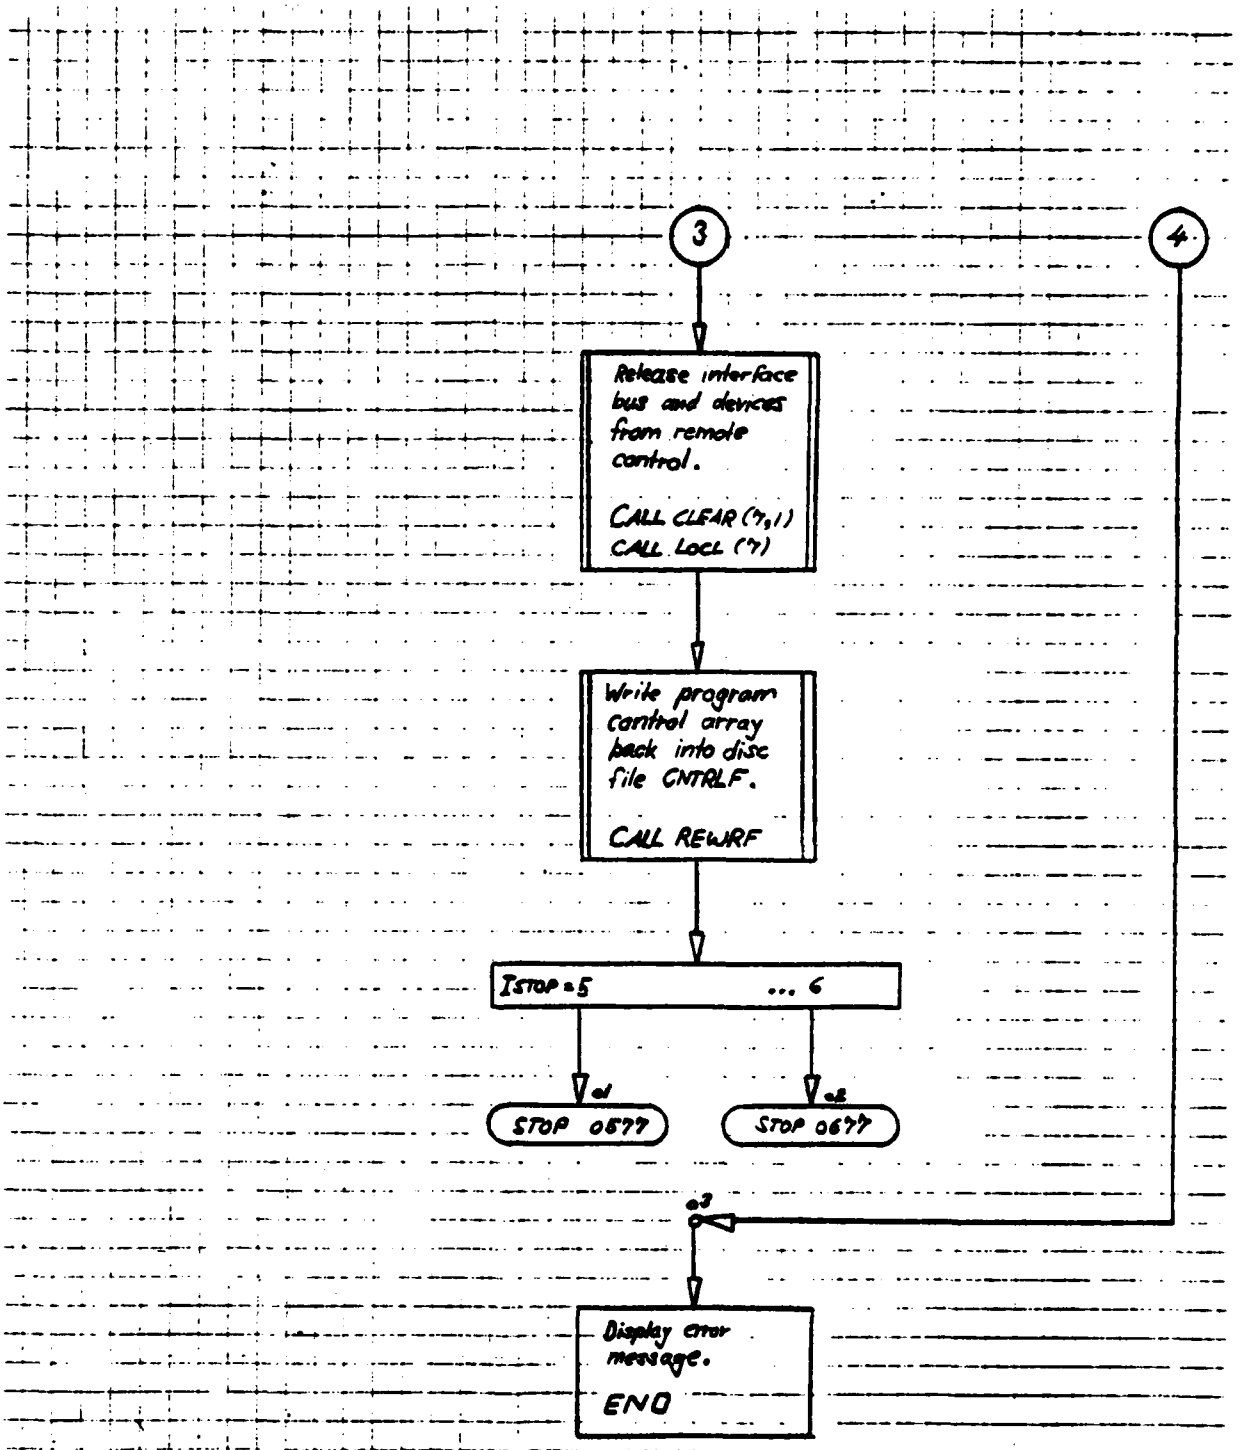
10 Digital Voltmeter (DVM)
12 Digital Counter
15 Scanner #2
7 HP. Interface bus



3
4
Release interface bus and devices from remote control.
CALL CLEAR (7,1)
CALL LOCL (7)
Write program control array back into disc file CNTRLF.
CALL REWRF
ISTOP = 5
... 6
STOP 0677
STOP 0677
Display error message.
END

5.2. SUBROUTINE COMB:

PURPOSE: Acquisition of flow data from the transonic 1-stage axial compressor using a pneumatic 4-hole combination probe. The data necessary for the reduction procedure (PROGRAM REDCO: Reduce Combination probe data) are recorded also. Up to 24 different radial positions can be recorded. Taking more than one scan at one and the same radial position should be avoided, because the reduction program (originally written by R. Shreeve for the Laboratory's HP 9830 calculator and rewritten by F. Neuhoff for the more advanced HP 21 MX computer) is not set up for this condition.

ARGUMENTS: None

EXTERNALS: TIME, SCANR, ACQN, CREAT, PURGE, OPEN, WRITF, CLOSE

COMMON BLOCKS: CIBUF, CONTR, FMP. For detailed explanation refer to the TXCO2 description.

MNEMONIC ABBREVIATIONS:

RE ... Repeat data acquisition at this radial position.

NE ... Proceed to the next radial position.

EN ... End survey at this operating condition.

UP ... Update position readings of probes prior to data taking.

TA ... Initialisation command to take data.

TR ... Transfer raw data to HP 9830.

ST ... Store raw data in 21 MX disc file.

PU ... Allow purge of an existing data file.

ERROR MESSAGES: None

PROCEDURE: For more detailed information, study the flow chart. After having assigned the accounting data, assigned the I/O references, COMB asks the operator whether the radial survey takes place ahead of the (IPOS = 1) rotor or behind the (IPOS = 2) rotor. IPOS later will be used to identify the correct data port (see Appendix A.1: Data Locations). The raw data array IBUF - which is set equivalent to real array PDAT (Prob Data; used instead of IBUF, which is an integer array) is first preset with zeroes. Before the operator goes ahead and allows the subroutine to gather data (Input: TA; see key to raw data array), he can monitor the probe positions by updating its reading (Input: UP), until the probe is manually set to the desired position. Upon completion of the data scan the acquired data are printed and the next step depends on the operator's decision. If a preliminary check reveals erroneous data, the scan at this radial position should be repeated (Input: RE). If the data are correct, the operator either proceeds to the next radial position (Input: NE) or terminates the radial combination probe survey (Input: EN) at this operating condition. The subroutine then asks where to dump the data. When this routine was developed the data reduction program for the combination probe was not available in the 21 MX system, hence the option to transfer the data to the 9830 calculator (Input: TR) was used. But the data can as well be stored in a 21 MX disc file (Input: ST). If the raw data file with the automatically

determined name already exists, the operator either allows overwriting the existing file (Input: PU) or renames the current data file (Input: any alphabetic character other than T). The subroutine terminates printing the data file name at the bottom of the data documentation page.

DATA FILE: The default file name is T5rrss (rr ... ASCII converted run #; ss ... ASCII converted sequential #).

VARIABLES:

IBUF (1664)	integer	buffer array
CNTRL (256)	integer	control array
IDCB (144)	integer	data control block, used for FMP calls
IFILE (3)	integer	array to contain current file name
ISIZE (2)	integer	specifies # of records and record length
ISECU	integer	security code of data file
ICR	integer	cartridge reference number, where the raw data file is located
JSECU	integer	ASCII converted security code
JCR	integer	ASCII converted cartridge reference number
PDAT(21,24)	real	raw data array, set equivalent to IBUF

POS (7)	real	array to contain probe positions
NOLF	integer	suppresses line feed
NOCR (2)	integer	suppresses line feed and carriage RETURN
ICLR (3)	integer	clears line above cursor
IDCBS	integer	length of data control block
IENTR	integer	multiple entry flag
IDOC	integer	count of current program run
IDOCF	integer	count of current data file sequential #
ITYPE	integer	type of raw data file
IL	integer	number of words to be transferred in FMP calls
LI	integer	LU# of standard input device (terminal)
LO	integer	LU# of standard output device (line printer)
IPOS	integer	Flag to indicate measurement location
IMON	integer	ASCII converted month of current year
IYEAR	integer	ASCII converted last two digits of current year
IDAY	integer	ASCII converted day of the month
IHOUR	integer	ASCII converted hour of the day (24 h clock)
IMIN	integer	ASCII converted minute of the hour

JI	integer	Subscript for data array PDAT
IS	integer	LU# of the selected scanner
IC	integer	Instrument code (DVM ... 1 and digital counter ... 3)
I2	integer	Subscript for position array POS
J3	integer	Contains channel of desired scanner
IDUM	integer	Decision variable
IW	integer	Determines delay in tens of milliseconds between closing S/V port and DVM reading
JO	integer	Number of selected S/V
SUM	real	Variable used to compute average
ISYNCH	integer	Synchronisation variable to coordinate data transfer 21 MX ⟶ 9830
NEW	integer	Scratch variable used to rename files

Key to data array PDAT

PDAT (1,J1) Barometric pressure p_{BARO}

PDAT (2,J1) KULITE reference pressure

PDAT (3,J1) Combination probe pressure p_1

PDAT (4,J1) Combination probe pressure p_{23}

PDAT (5,J1) Combination probe pressure p_4

PDAT (6,J1) Total pressure ahead of compressor p_t

PDAT (7,J1) Static port in casing #2 , S_2

PDAT (8,J1) Static port in casing #13 , S_{13}

PDAT (9,J1) Average reading of 4 static ports in Hub (#2 thru 5) $(H_1 + H_2 + H_3 + H_4)/4$

PDAT (10,J1) Pressure ahead of compressor flow meter orifice P_1 nozzle compr

PDAT (11,J1) Temperature ahead of compressor flow meter orifice T_1 nozzle compr

PDAT (12,J1) Pressure drop across compressor flow meter orifice $p_{nozzle\ compr}$

PDAT (13,J1) Temperature reading from reference probe T_{ref}

PDAT (14,J1) Differential temperature reading from the combination probe to the reference probe T_{probe}

PDAT (15,J1) Radial immersion of the combination probe

PDAT (16,J1) Yaw angle of the combination probe

PDAT (17,J1) Case angle

PDAT (18,J1) Compressor RPM

PDAT (19,J1) Test run #

PDAT (20,J1) Test # of this run

PDAT (21,J1) Point # of this test

J1 = 1 ... 24 indicates # of radial position.

5.3. SUBROUTINE STDY:

PURPOSE: Acquisition of flow data from the transonic 1-stage axial compressor using the steady state instrumentation. All data, gathered by this subroutine, will be used for the reduction (PROGRAM REDST: Reduce Steady state data; see section 8.3 of this report). The data array is designed to both resemble the data source location matrix (see Appendix A.1) and to discriminate groups of similar data by blank lines (Appendix A.2). CH3(1) through CH3(5), which contain all the pressures needed to calculate the flow rates, and CH3(6), which is left blank, separates this group of data from the next one. The reason is to allow the investigator a quick check and verification of crucial data. The "units" of the readings depend on the amplifier settings, but usually each channel is calibrated to allow the operator to read voltages as a quantity in engineering units. As far as possible, amplifier drift is traced by the program (CH1(1), CH2(1) etc.). (The author is indebted to Laboratory's manager, Mr. Jim Hammer, who, with admirable patience, instructed the author in how best to handle data and data systems.)

ARGUMENTS: IRUN; if IRUN is set to 0 (zero), taking pressure readings from the Scanivalves (S/V) is skipped. This option was needed when the subroutine was first written so that frequent debugging runs did not put additional loads on the S/V's. The standard entry is: IRUN = 1. Only then will the reduction program REDST perform correctly.

EXTERNALS: TIME, ACQN, SCANR, CREAT, PURGE, OPEN, WRITF, CLOSE

COMMON BLOCKS: CIBUF, CONTR, FMP. For detailed explanation refer to the TXCO2 description

MNEMONIC ABBREVIATIONS:

RP ... Repeat data acquisition at this operating condition

RT ... End data acquisition and return to calling program

PU ... Allow purge of an existing data file

ERROR MESSAGES: None

PROCEDURE: For more detailed information, study the flow chart. After having assigned the accounting data and defined the I/O references, STDY presets all elements of the raw data array with -0.999999, which definitely never will occur as a data reading. Next, unless IRUN equals 0 (zero), the pressures on Scanivalves 1 and 4 are read. The voltages from scanner #1 (LU# = 8) and scanner #2 (LU# 15) are read next, not depending on the value of IRUN. Note, that the allocation for the voltages in the raw data array provides blocks of similar data, separated by blank lines. A set of control parameters (CNTRL (1) thru CNTRL (6); and CNTRL (15) and the case angle - which needs to be put in manually - completes the steady state data. Then the raw data is printed to allow the operator to look at and to verify the newly acquired data. The data scan can either be repeated (Input: RP) or the subroutine terminates (Input: ST) storing the data in a type 1 disc file. If the automatically determined name for the data file already exists,

the operator either allows overwriting the existing file (Input: PU) or renames the current data file (Input: any alphabetic character other than T). Finally data file name and time are printed at the bottom of the data documentation page.

DATA FILE: The default file name is T4rrss (rr ... ASCII converted run #; ss ... ASCII converted sequential #); see Appendix A.2: Steady State Data Array. CH4 (1) through CH4 (26) are not used, because the reduction program will write its results into these slots.

VARIABLES:

IBUF (1664)	integer	buffer array
CNTRL (256)	integer	control array
IDCB (144)	integer	data control block, used for FMP calls
IFILE (3)	integer	array to contain current file name
ISIZE (2)	integer	specifies # of records and record length
ISECU	integer	security code of data file
ICR	integer	cartridge reference number, where the raw data file is located
JSECU	integer	ASCII converted security code
JCR	integer	ASCII converted cartridge reference number
DATA (48,4)	real	raw data array, set equivalent to IBUF

NOLF	integer	suppresses line feed
NOCR (2)	integer	suppresses line feed and carriage RETURN
ICLR (3)	integer	clears line above cursor
IENTR	integer	multiple entry flag
IDOC	integer	count of current program run
IDOCF	integer	count of current data file sequential #
ITYPE	integer	type of raw data file
IL	integer	number of words to be transferred in FMP calls
IFRST	integer	temporary buffer variable
LI	integer	LU # of standard input device (terminal)
LO	integer	LU # of standard output device (line printer)
J1	integer	subscript for data array DATA, specifies channel
J2	integer	subscript for data array DATA
IRUN	integer	control variable
JO	integer	number of selected S/V
IW	integer	determines delay in tens of milliseconds between closing S/V port and DVM reading
TARE1	real	drift of amplifier S/V#1 during test run

TARE2	real	drift of amplifier S/V #4 during test run
IS	integer	LU # of the selected scanner
IC	integer	instrument code (DVM ... 1 and digital counter ... 2)
J3	integer	contains channel of scanner
NO(2)	integer	ASCII text to be printed, if value of DATA (J2,J1) = -.999899
IDUM	integer	decision variable
IMON	integer	ASCII converted month of current year
IDAY	integer	ASCII converted day of the month
IYEAR	integer	ASCII converted last two digits of current year
IHOUR	integer	ASCII converted hour of the day (24 h clock)
IMIN	integer	ASCII converted minute of the hour
NEW	integer	scratch variable used to rename files

8
9
Acquire data (pressures, temperatures, torque, speed & probe positions) from scanner-DVM system (IC=1) and scanner-counter system (IC=2). Since groups of similar data are separated by a blank line, this flow chart refrains from mapping all DO loops. First the raw data array channel 3 (J=3) is filled.
Fill up raw data array channel 4 (J=4) with data and control variables as read from the control array CNTRL; manually input case angle into DATA(43,J1).
DATA(43,J1) = 3939

6. PROGRAM TXCO3

6.1. DESCRIPTION

TXCO3 is a son program of the father program TXCOØ, by which it is scheduled if one of the following operations is desired:

7 - Check the instrumentation

8 - Manipulate the program control array CNTRL.

When scheduled by TXCOØ, which suspends operation while the son program TXCO3 executes, the program TXCO3 reads the program control array from the disc, sets the HP interface bus and the measurement and control devices to remote control, preprograms the digital voltmeter (DVM), the scanners and the counter. CNTRL(50) is the actual decision variable to select and call the subroutine, which performs the desired operation. When this subroutine has terminated, the interface bus and the devices are released from remote control and the control array is written into a disc file, so that the next TXCO module can read it. The correct termination of each subroutine can be verified by checking the stop codes. Note that all stop codes ending on 77 indicate correct execution of a subroutine.

CNTRL(50)	Subroutine	STOP Code
7	CHECK	TXCO3 : STOP 0777
8	CHNGE	TXCO3 : STOP 1077

EXTERNALS: REWRF, ABRT, RMOTE, CHECK, CHNGE, CLEAR, LOCL

COMMON BLOCKS: FMP, CIBUF, CONTR.

The FORTRAN-IV compiler for the HP 21 MX computer requests COMMON blocks to be predefined in a BLOCK DATA subroutine prior to using a COMMON block in a program, subroutine or function.

BLOCK DATA Subroutine	Arrays & Variables	Length in Words
FMP	IDCB,IFILE,ISIZE,ISECU,ICR	$227B = 151_{10}$
CIBUF	IBUF	$3200B = 1664_{10}$
CONTR	CNTRL	$400B = 256_{10}$

The arrays and variables allocated by the COMMON block FMP are frequently used for the data transfer from and to the disc. COMMON block CIBUF is designed to take the largest raw data array in the TXCO data acquisition and reduction system - IBUF(1664) in subroutine FREER. The program modules CHECK and CHNGE do not use the complete area allocated by CIBUF. COMMON block CONTR allocates the space for the control array CNTRL.

MNEMONIC ABBREVIATIONS: None

ERROR MESSAGES: If CNTRL(50) is less than 7 or greater than 8, no subroutine has been selected and the program terminates outputting an error message (FORMAT #102) to the standard input device, i.e. the terminal.

PROCEDURE: For more detailed information, study the flow chart and the information given in the subroutine descriptions.

DATA FILE: None

VARIABLES IN BLOCK DATA FMP:

ICDB (144)	integer	data control block
IFILE (3)	integer	array to contain file name
ISIZE (2)	integer	array to contain # of records in the first and record length in 16-bit-words in the second word
ISECU	integer	security code of data file
ICR	integer	cartridge reference number, where data file is located

VARIABLES IN BLOCK DATA CIBUF:

IBUF (1664)	integer	buffer array for the raw data

VARIABLES IN BLOCK DATA CONTR:

CNTRL (256)	integer	program control array

VARIABLES IN PROGRAM TXCO3:

CNTRL (256)	integer	program control array
NOLF	integer	suppresses line feed
LI	integer	LU # of standard input device (terminal)
ISTOP	integer	control variable to select STOP code

STOP 10777
Display error message
END

6.2. SUBROUTINE CHECK:

PURPOSE: This subroutine enables the investigator to (independently from the data acquisition modules ABSRV, CALIB, FREER, PACER, COMB and STDY) check all data locations to troubleshoot or verify the transonic compressor test rig measurement system.

ARGUMENTS: LO ; this variable specifies the output unit where the protocol of the check is directed to. In any case, the data are displayed on the standard input device (terminal LI) and if LO is equal to LI, double output is suppressed. The selection of LO = 6 (line printer) is an appropriate choice for a hardcopy of the check protocol.

EXTERNALS: ACQN, SCANR, RPACE

COMMON BLOCK: CONTR; for detailed explanation refer to the TXCO3 description.

MNEMONIC ABBREVIATIONS: None

ERROR MESSAGES: None

PROCEDURE: For more detailed information, study the flow chart. After having assigned the I/O reference, CHECK asks the operator which particular system should be checked.

Instrumentation code	system being checked
1	S/V-S/V controller - scanner - DVM - system

Instrumentation Code	System Being Checked
2	amplifier - scanner - DVM - system
3	Pacer

The operator then selects the desired code and the program branches.

i) S/V - S/V controller - scanner - DVM - system

The operator has to input the number (1 thru 5) of the S/V, the low port and the high port. Erroneous input will cause the program to re-request the data. If S/V #2 is selected and either low or high port are odd, they will be increased to the next even number. In increments of 1 (2 resp., if S/V #2 is addressed) the subroutine steps from low to high port, taking a reading of each. The result is displayed and printed immediately. Upon completion the operator is asked whether another check shall be done. The answer is YES or NO, and if YES is entered, SUBROUTINE CHECK is run again from the beginning.

ii) amplifier - scanner - DVM - system

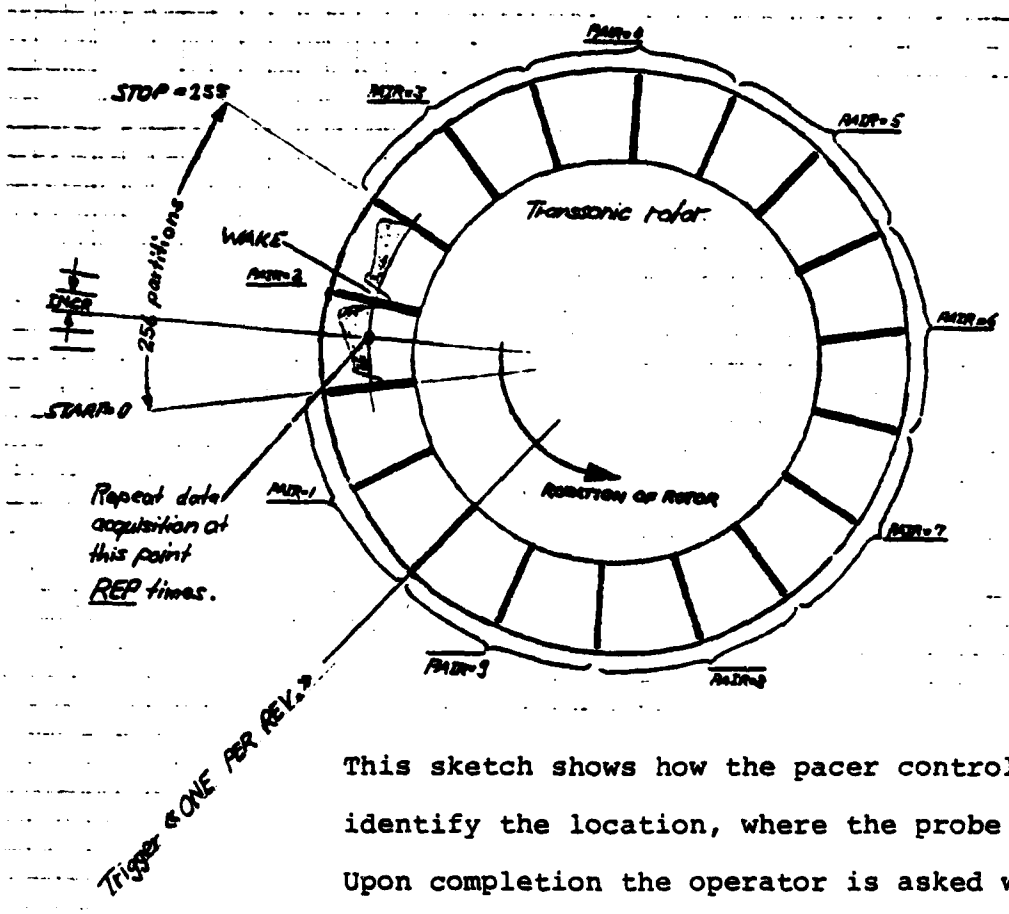
The operator has to input the number (1 or 2) of the scanner, the low channel and the high channel. Erroneous input of the scanner # will cause the program to re-request the data, whereas no check is made whether the boundaries for the scan, low channel ILOW and high channel IHIGH, are correct. In increments of 1 the subroutine steps from low channel to high channel, taking a reading at each port. The result is displayed and printed immediately. Upon completion, the operator is

asked whether another check shall be done. The answer is YES or NO, and if YES is entered, SUBROUTINE CHECK is run again from the beginning.

iii) Pacer

The operator has to input the pacer control parameters:

ADCHNL	A/D analog input channel to be selected by the A/D converter multiplexer.
PAMO	Pacer mode = 1 allows pacer to trigger A/D conversion at the specified position in any blade interval. The variable PAIR is ignored. = 2 causes pacer to select blade pair # PAIR.
PAIR	# of blade pair selected (1 - 9)
START	Start count to step through blade passage
INCR	Increment to step through blade passage
STOP	Stop count to step through blade passage
REP	Number of repetitions at each individual point



This sketch shows how the pacer control parameters identify the location, where the probe takes data. Upon completion the operator is asked whether another check shall be done. The answer is YES or NO, and if YES is entered, start to read this section SUBROUTINE CHECK again.

DATA FILE: None

VARIABLES:

LO	integer	LU# of standard output device (line printer)
CNTRL(256)	integer	program control array
NOLF	integer	suppresses line feed
NOCR(2)	integer	suppresses line feed and carriage return
ICLR(3)	integer	clears line above cursor

ADCHNL	integer	Pacer control parameter	see section iii) for detailed explanation
PAMO	integer	Pacer control parameter	
PAIR	integer	Pacer control parameter	
START	integer	Pacer control parameter	
INCR	integer	Pacer control parameter	
STOP	integer	Pacer control parameter	
REP	integer	Pacer control parameter	
LI	integer	LU# of standard interactive input device (system terminal)	
LINES	integer	line count	
IDIUM	integer	decision variable	
IPORT	integer	# of desired S/V (1 — 5)	
ILOW	integer	low port of desired S/V	
IHIGH	integer	high port of desired S/V	
ISTEP	integer	increment to step from low to high port	
IW	integer	delay between closing S/V port and taking the DVM reading in tens of ms.	
V	real	pressure reading (raw data)	
ISCR	integer	# of desired scanner (1 or 2)	
ILOW	integer	low channel of desired scanner	
IHIGH	integer	high channel of desired scanner	
LS	integer	LU# of the desired scanner	
D	real	voltage reading (raw data)	
AVRGE	real	average voltage as returned from subroutine RPACE

Check SV - SVcontroller - scanner - DVH - system

6.3. SUBROUTINE CHNGE:

PURPOSE: Change any element of the program control array CNTRL on line and display any element of CNTRL.

ARGUMENTS: None

EXTERNALS: CODE, REWRF

COMMON BLOCK: CONTR; for detailed explanation refer to the TXCO3 description.

MNEMONIC ABBREVIATIONS:

C ... Change CNTRL (i) to new value

D ... Display current value of CNTRL (i)

R ... Return to the calling program

Note: C is followed by the value of ≪i≫ and the new value for ≪CNTRL (i)≫ and D is followed by the value of ≪i≫.

ERROR MESSAGES: None

PROCEDURE: For more detailed information, study the flow chart. After having assigned the I/O reference and reset the line count, the operator is asked what to do. The input in the first inverse video box specifies where to branch to.

i) Change CNTRL (i) to new value Input: C

The control character C is followed by the value of ≪i≫ and the new value for ≪CNTRL (i)≫. Each of the latter data items has to be aligned to the right margin of the two

following inverse video boxes. If the input is to be compiled as ASCII code, the identifier 2H has to precede the two input characters.

EXAMPLE A) Suppose, the time delay IW between closing a S/V port and taking the DVM reading shall be changed to 1 second, which is 100*10 milliseconds. Enter

[C] [250] [100]

and press the RETURN key. The subroutine responds displaying the message CNTRL (250) changed from 80 to 100. Where 80 is the previous value of CNTRL (250).

EXAMPLE B) The character, used to display the just acquired wave form in subroutine PACER shall be changed to the asterisk (= 2H*␣). Enter

[C] [249] [2H*␣]

blank, because subroutine PICTR outputs this item in A1-Format

and press the [RETURN] key. The subroutine responds displaying

CNTRL (249) changed from 2H+␣ to 2H*␣ .

where the add sign (= 2H+␣) was previously used for the plot.

ii) Display actual value of CNTRL (i) [Input: D]

The control character C is followed by the value of ≪i≫ and, only if the element CNTRL (i) shall be displayed in ASCII-mode, the string ≪2H≫ . The data for ≪i≫ has to be aligned to right margin of the second inverse video box and ≪2H≫ has to be centered in the third box.

EXAMPLE A) Display the value for the cartridge reference number, where the raw data files are located. Appendix A.3 (Program Control Array) reveals that you have to look into CNTRL(30). Enter

[D] [30] [ ]

and press the RETURN key. The subroutine responds by informing you that

The actual value of CNTRL (30) is 26.

EXAMPLE B) Display the first two characters of the name of the raw data file, which are written into CNTRL (32). Since the file name is ASCII coded, the ASCII-identifier ≪2H≫ must not be forgotten. Enter

[D] [32] [2H]

and press the [RETURN] key. The subroutine responds by informing you, that

The actual value of CNTRL (32) is 2HT5.

This information reveals that the last data acquisition was a combination probe survey, since there all data file names start with ≪T5≫ .

iii) Return [Input: R]

Enter R; Now the subroutine asks, whether to clear the informative responses, displayed by this subroutine previously. Inputting anything else but NO initializes the program to clear the screen.

Then the subroutine terminates writing the modified control array back into disc file.

FLOW CHART SUBROUTINE CHNGE

7. UTILITY SUBROUTINE PACKAGE TXCOU

7.1. Description

Subroutines and functions, which are commonly used by either TXCO2, TXCO2 or TXCO3, are contained in the utility package TXCOU (source code is saved in file &TXCOU; relocatable binary code is saved in file %TXCOU). Thus the length of the TXCO1, TXCO2 or TXCO3 source files can be kept to minimum, which allows editing and recompiling TXCO1, -2, -3 separately, which saves time. When loading TXCO1, -2, -3, the load of the utility subroutines has to be included using the multiple search loader command (MS,%TXCOU). Since the utility subroutines and functions are short and straightforward, the comment statements and program explanation included in the code serve to describe them. The present section briefly outlines the utility subroutine package.

Name	Purpose	Author
ACQN	Positions Scanivalve (S/V) and reads DVM	Geopfarth
CNTL	Closes scanner channels, which control the S/V controller, HG78K	Geopfarth
CURVE	Computes coefficients for a linear curve fit	McGuire
ICON	Converts a one or two digit integer into a two character ASCII string	Geopfarth

Name	Purpose	Author
IPORT	Interrogates S/V controller and returns the present port #	Geopfarth
PICTR	Uses the (24 x 80 dot) CRT of a terminal for a graphics display of data acquired with the PACER	Zebner
REWRF	Data transfer disc file to program array and vice versa	Zebner
RPACE	Triggers A/D through the PACER and calculates the average voltage	Zebner
SCANR	Closes scanner channel and reads the DVM or digital counter	Geopfarth
TIME	Obtains date and time in ASCII-format	Zebner
WAIT	Causes a defined time delay	Geopfarth (Original) Zebner (Modification)

REAL FUNCTION ACQN

Arguments: INTEGER: IVALVE, IADES, IW

IVALVE - - - Desired S/V #

IADES - - - Desired port # of S/V

IW - - - - - Time delay in tens of ms between closing transducer relay and taking the DVM reading

Example: The pressure on S/V #4, Port #18 is to be read with the time delay to be 0.5 sec (= 500 ms = 50 x 10 ms). The correct call is

```
IVALVE = 4
IPORT = 18
IW = 50
PRES = ACQN (IVALVE, IPORT, IW)
```

or

```
PRES = ACQN (4, 18, 50)
```

In both cases the DVM reading is written into the real variable PRES.

It is desirable to step forwards systematically and sequentially through the required parts of a S/V in order to reduce unnecessary wear. Whenever a S/V is scanned, the operator should watch the data system closely. In some cases (e.g. if the HP 9830 is brought on line) the HP-Interface bus and the devices may be downed. If this happens when the program ACQN has closed the scanner channels (on scanner #1) which either resets or advances the S/V the S/V relay will burn out. To prevent damage, the operator must turn off the power to scanner #1 immediately, then bring the data system up again using the UP-command (see HP manuals).

SUBROUTINE CNTL (ICHAN, IDEL, ISTEP, K)

Arguments: INTEGER: ICHAN, IDEL, ISTEP, K

ICHAN - - - Channel # of scanner #1 (LU# = 8)

IDEL - - - Number of repetitions to close the scanner channel

ISTEP - - - Increment to step from 1 through IDEL

K - - - - - Function code

K = 1 Close for 10 ms, wait for 150 ms; Repeat "IDEL" times; return

K = 2 Close for 10 ms, wait for 4 sec; return

K = 3 Close; return

An example is unnecessary since the only subroutine to use SUBROUTINE CNTL is the REAL FUNCTION ACQN, which is itself a utility. The user won't have to deal with CNTL.

SUBROUTINE CURVE (N, X, Y, SLOPE, SECON)

Arguments: INTEGER: N

REAL: X(N), Y(N), SLOPE, SECON

N - - - - Number of data points

X(N) - - - Abscissa of data points

Y(N) - - - Ordinals of data points

SLOPE - - Slope of linear curve fit

SECON - - Intercept of linear curve fit

Example: Suppose the following (N = 6) pairs of data points shall be approximated by a linear curve fit:

X(1) = 1.0 Y(1) = 105.6

X(2) = 2.5 Y(2) = 105.4

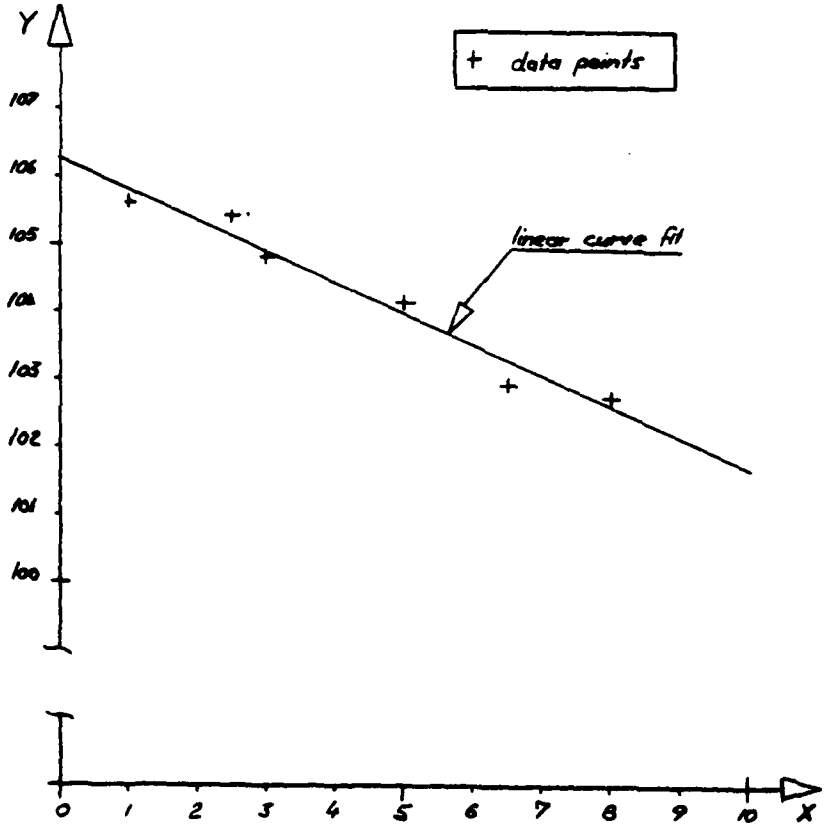
X(3) = 3.0 Y(3) = 104.8

X(4) = 5.0 Y(4) = 104.1

X(5) = 6.5 Y(5) = 102.9

X(6) = 8.0 Y(6) = 102.7

The situation is shown in the following sketch:



To obtain the slope and the intercept of the linear curve fit (which is derived using the least squares criterion), program

CALL CURVE (6, X, Y, SLOPE, SECON)

and the results will be returned from SUBROUTINE CURVE

SLOPE = -.461

SECON = 106.247

INTEGER FUNCTION ICON

Arguments: INTEGER: I, N

I, N - - - Two integer numbers to be added

ICON - - - The result of the addition (which should not exceed two digits), but ASCII converted.

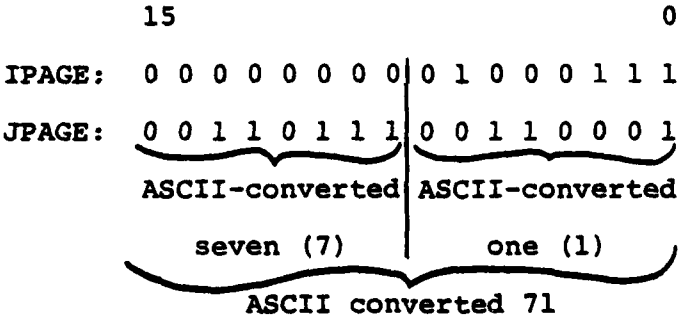
Example: Suppose the data documentation page IPAGE shall be converted to an ASCII-string named JPAGE. The correct call is:

JPAGE = ICON (IPAGE, Ø)

or

JPAGE = ICON (Ø, IPAGE)

The bit structure, if IPAGE is 71_{10}, is as follows:



INTEGER FUNCTION IPORT

Arguments: INTEGER: IVALVE

IVALVE - - - Desired S/V (1 through 5)

Example: The call

IWHERE = IPORT(5)

returns the present port # of S/V #5 and writes it into the variable IWHERE.

SUBROUTINE PICTR

Arguments: INTEGER: LO, NUMBER, NEWPG, ICL, ISIGN

REAL: AMPL

LO - - - - Defines terminal LU# (either 1 or 18)

NUMBR - - Identifier to appear in the "drawing"

NEWPG - - No significance! Will be altered by PICTR

ICL - - - No significance! Will be altered by PICTR

ISIGN - - Character to be used for the drawing

AMPL - - - Amplitude range of the raw data returned to the calling program

Subroutine PICTR is designed for the TXCO1-subroutine PACER, from which it gets the data through the COMMON block CIBUF. PICTR uses the enhanced display capabilities of the video terminal to produce a "drawing" which, of course, is of limited resolution. It allows the operator to verify the acquired raw paced run data qualitatively by checking the "drawing" against the oscilloscope display. See the listing of subroutine PACER, if an example is needed.

SUBROUTINE REWRF

Arguments: INTEGER: IREWRF, IWHATA

IREWRF - - Determines whether the array indicated by IWHATA shall be read from a disc file into an array or whether it shall be written into a disc file

IREWRF = -1 Read data from disc file into array

IREWRF = +1 Write data from array into disc file

IWHATA - - Specifies the type of data to be transferred

IWHATA = 1 Array IBUF ↔ disc file IBUFF

IWHATA = 2 Array CNTRL ↔ disc file CNTRLF

This subroutine relieves the individual TXCO1, -2, -3 subroutines from the routine task of data transfer between disc and program (CP).

Example: The four applications are:

i) Read the program control array from disc file CNTRLF::26 into array CNTRL: CALL REWRF (-1, 2)

ii) Write the program control array from array CNTRL into disc file CNTRLF::26: CALL REWRF (1, 2)

iii) Read the raw data buffer from disc file IBUFF::26 into array IBUF: CALL REWRF (-1, 1)

iv) Write the raw data buffer from array IBUF into disc file IBUFF::26: CALL REWRF (1, 1)

SUBROUTINE RPACE

Arguments: INTEGER: ADCHNL, PAMO, PAIR, START, INCR, STOP, REP, IPRINT, LO

REAL: AVRGE

ADCHNL - - A/D input channel to be selected (0...15)

PAMO - - - Pacer mode (1 or 2)

PAIR - - - Blade pair (1...9)

START - - - Start location (in counts) for data scan across the blade passage

INCR - - - Step size (in counts) to scan across the blade passage

STOP - - - Stop location (in counts) for data scan across the blade passage.

REP - - - - Number of repetitions at each location in the blade passage

IPRINT - - Flag to decide whether to output intermediate information

IPRINT = 1 Print all intermediate data and suppress pointer at the terminal

IPRINT = Ø Suppress printed output and initialize pointer at the terminal

LO - - - - LU# of device for printed output

AVRGE - - - Average voltage of paced run data

This subroutine is the control program to acquire data from the A/D converter in the synchronized PACER mode. (See also the description of subroutine PACER (Section 4.5), where the synchronized sampling is explained.) Although the (decoded) voltages from the A/D converter are REAL numbers between -1.0 volt and +1.0 volt, the data storage uses an integer array. Before writing the voltages into the data array, they are multiplied by 10,000. Note that if one of the PACER control parameters is out of the defined range, it is set to a default value without outputting any warning. The subroutine contains a large number of I/O statements

which were necessary during the development of the TXCO program system. In order to increase speed, the unnecessary statements should be removed. A further improvement would be a conversion from FORTRAN to ASSEMBLER programming language. An example of a call to subroutine RPACE is contained in the description and listing of subroutine PACER (Section 4.5).

REAL FUNCTION SCANR

Arguments: INTEGER: LU, ICHAN, K

LU - - - - Logical Unit # of the desired scanner (either 8 - scanner #1, or 15 - scanner #2)

ICHAN - - - Scanner channel (integer)

K - - - - - Instrument code

K = 1 Read the DVM

K = 2 Read the digital counter

Example A: To obtain the torque reading from the transonic compressor test rig, which is fed into scanner #1 (LU = 8), channel 36, program

```
LU = 8
ICHAN = 36
K = 1
TORQUE = SCANR (LU, ICHAN, K)
or
TORQUE = SCANR (8, 36, 1)
```

In both cases the DVM reading is written into the real variable TORQUE.

Example B: To obtain the RPM of the Allis-Chalmers (central air supply) compressor, program

```
LU = 8
ICHAN = 15
K = 2
RPMAC = SCANR (LU, ICHAN, K)
or
RPMAC = SCANR (8, 15, 2)
```

In both cases the reading of the digital counter is written into the real variable RPMAC.

Example	Instrument Code	Instrument Read
A	1	Digital Voltmeter
B	2	Digital Counter

SUBROUTINE TIME

Arguments: INTEGER: IMON, IDAY, IYEAR, IHOUR, IMIN, ISEC

IMON - - - ASCII converted month of the year

IYEAR - - - ASCII converted last two digits of current year

IDAY - - - ASCII converted day of the month

IHOUR - - - ASCII converted hour (24-hour clock) of the day

IMIN - - - ASCII converted minute of the hour

ISEC - - - ASCII converted second of the minute

IMON, IDAY and IYEAR are obtained from the program control array; IHOUR, IMIN and ISEC are obtained from the system

clock through an EXEC call; all variables are returned to the calling program.

Example: Suppose the system clock is set correctly and the control array CNTRL is defined, i.e., CNTRL was read from the disc file and adjusted to the actual conditions; then the following code

```
      .
      .
      .
603 FORMAT ("Date & Time: "A2"/"A2"/"A2,2X,
   *A2":"A2)
    CALL TIME (IMON,IDAY,IYEAR,IHOUR,IMIN,ISEC)
    WRITE (6,6Ø9) IMON,IDAY,IYEAR,IHOUR,IMIN
      .
      .
      .
```

produces the following output:

```
      .
      .
      .
Date & Time:  Ø9/27/8Ø  21:57
      .
      .
      .
```

SUBROUTINE WAIT

Arguments: INTEGER: TWAIT

TWAIT - - - Time delay in tens of milliseconds

Example: To cause a defined time delay of 5,7 sec (= 5700 ms = 570 x 10 ms), program

```
ITWAIT = 570
CALL WAIT (ITWAIT)
```

or

```
CALL WAIT (570)
```

8. DATA REDUCTION PROGRAMS

Three data reduction programs can be initiated from within the TXCO system. They are the following:

(i) Program REDAB (Enter 9)

This program was written to reduce data from the A-B Kulite probe system following the method given in Ref 2, and outputs distributions of velocity magnitude and flow angles.

(ii) Program REDCO (Enter 10)

This program reduces survey data taken with the combination temperature-pneumatic probe and outputs distributions of pressure rise, temperature rise, Mach number, flow angle and losses.

(iii) Program REDST (Enter 11)

This program reduces data taken from fixed instrumentation and outputs the steady-state performance of the compressor.

The above programs are documented separately.

9. CONCLUSIONS AND RECOMMENDATIONS

The large quantity and variety of instrumentation used in the transonic compressor test facility required that data acquisition programs be provided for the different types of data. This was achieved using a particular program structure. Data reduction programs were strictly separated but geared to the acquisition modules through the use of standard data arrays. The data acquisition programs TXCO1, TXCO2 and TXCO3 have been described in detail and the operator commands are explained. The reduction programs are to be documented separately.

The need for easy-to-understand program control leads to a conflict. If interactive messages which explain the program flow and offer menus giving a selection of next logical steps are included, this introduces extended I/O operations and leads to long programs whose speed in execution is slowed considerably by the I/O's. On the other hand the I/O's may be kept to a minimum, which speeds up execution, but this may also lead to communication gaps between the program and the operator. Since the research on the transonic compressor test rig is carried out in large part by visiting researchers and postgraduate students, it was decided to program closer to the first alternative. However, a very useful compromise was achieved through the introduction of the program control array. Should experience in using the TXCO-system show that

the interactive messages, error processing, or the checking for erroneous operator input are too extensive, then the programs should certainly be trimmed.

At the time the programs were written, a graphic software package was not present in the operating system and therefore original plotter software was generated. The switch from "home made" to HP-supported graphics is recommended.

Finally, if the instrumentation system is changed, corresponding changes can be introduced into the appropriate program module, or a new one can be added. Also, the same or a similar program system can easily be adapted for use on any other test rig or calibration apparatus in the laboratory.

A.2. STEADY STATE DATA ARRAY

WORK SHEET TO DECODE THE DATA

ARRAY FOR THE STEADY STATE DATA

File name convention: raw steady state data T4RRSS
reduced steady state data T9RRSS

RR = ASCII converted run #
SS = file sequential # from this run

Note: In some cases the letter T (which stands for Transonic compressor) may be changed to any other character in order to prevent overwriting an existing data file.

Example: T40503 is the third data file from test run #5, that contains steady state data. The data reduction program REDST (Reduction steady state data) creates the file T90403 to take the reduced data from this run.

Due to interface bus problems the data acquisition program STDY sometimes has to be aborted, but may already have produced some valid raw data files. When the program is restarted, it tries to write to data files, whose names already exist. To avoid purging these files, the operator then interactively changes the first character of the data file name to U40503, e.g. The reduced data of course are in file U90503.

By the way, T40503 contains good data. You will find this file in cartridge 29 and can use it to get acquainted with REDST.

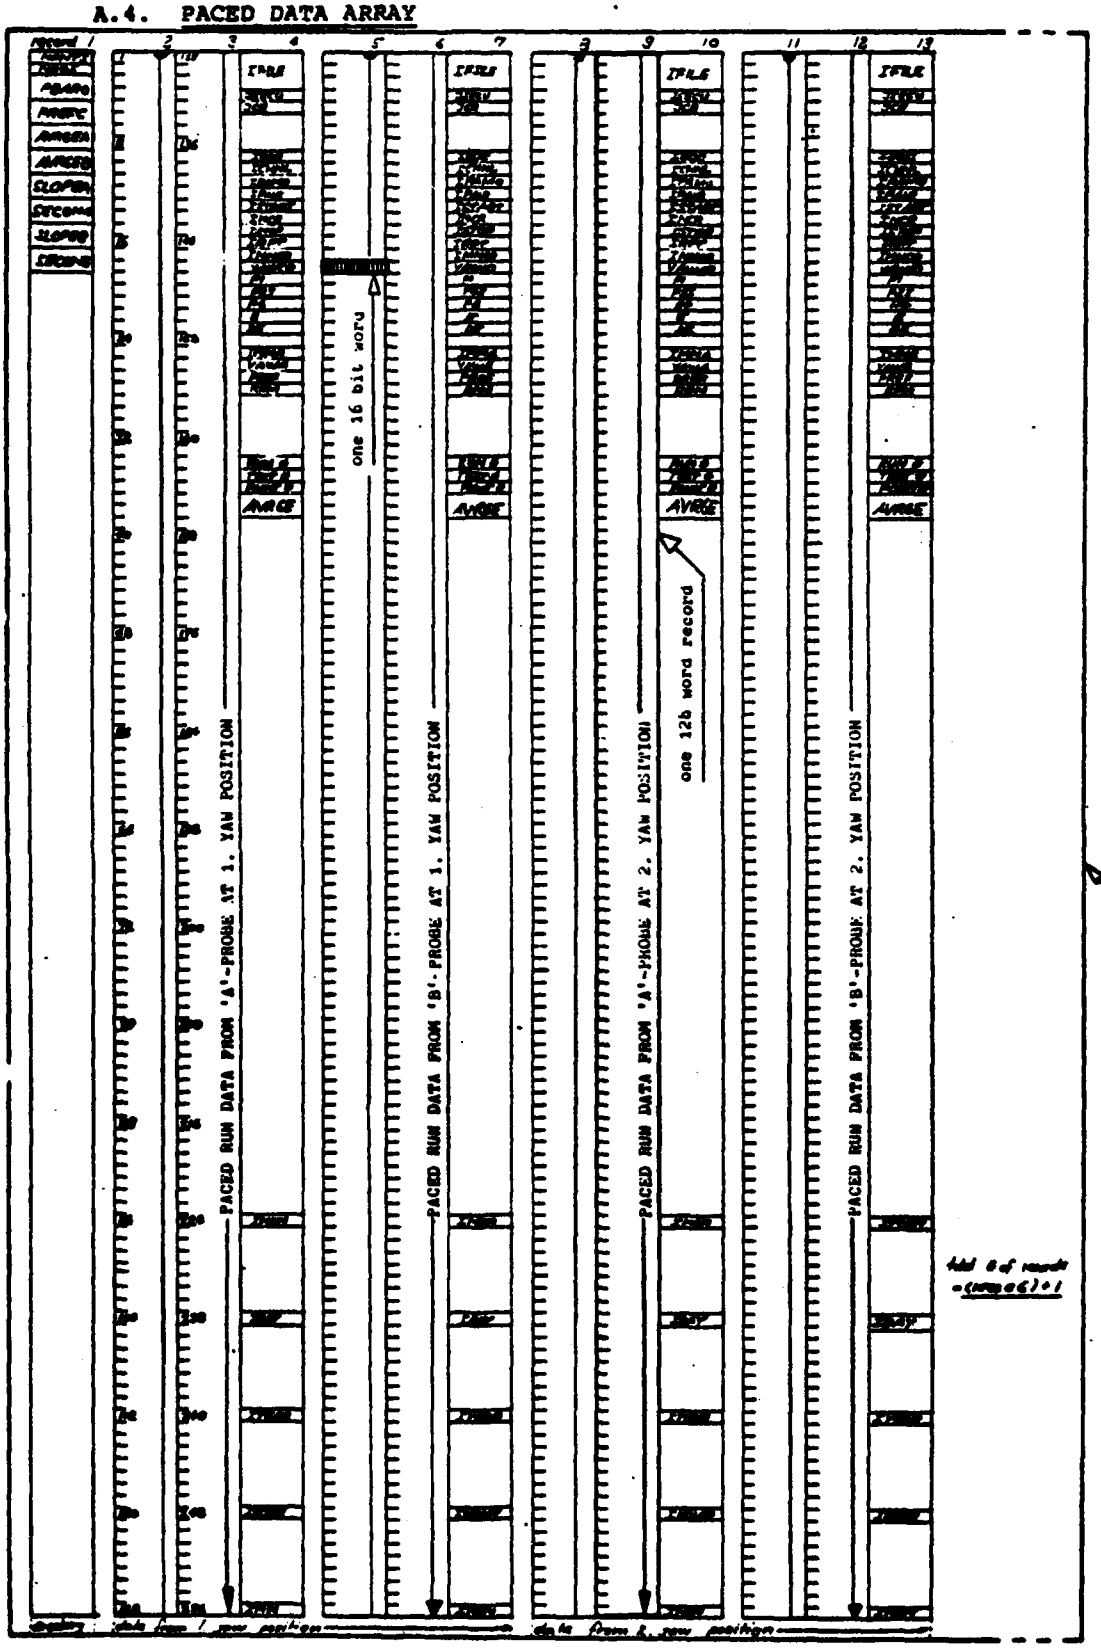
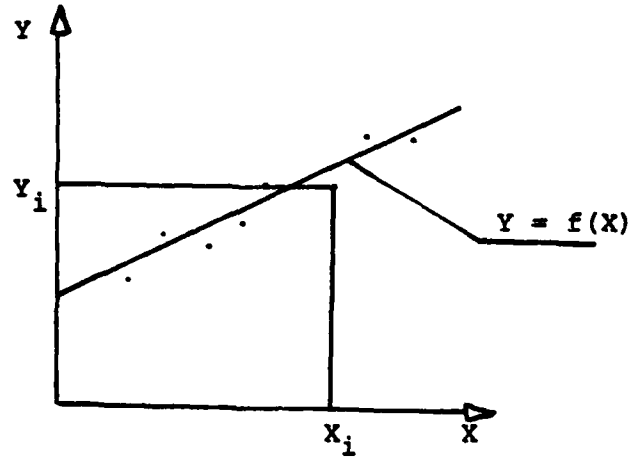
A.4. PACED DATA ARRAY



APPENDIX B. LINEAR APPROXIMATION BY METHOD OF LEAST SQUARES



Data: X_i and Y_i ; i = 1,...,NPNTSI

Equation: $Y = C_1 + C_2 \cdot X$

Difference for Each Data Point: $R_i = Y_i - f(X_i)$; i=1,...,NPNTSI

Sum of Squares of Differences: $$R = \sum_{i=1}^{NPNTSI} R_i^2 = \left[\sum_{i=1}^{NPNTSI} Y_i - (C_1+C_2 \cdot X_i)\right]^2$$

The value of R depends on the values of the coefficients C_1 and C_2. In order to determine a minimum value for R, the expression for R is partially differentiated with respect to C_1 and C_2 and the two derivatives are equated to zero. Differentiating,

$$\frac{\partial R}{\partial C_1} = \sum_{i=1}^{NPNTSI} 2 \cdot \left[Y_i - (C_1 + C_2 \cdot X_i)\right] \cdot (-1)$$

and

$$\frac{\partial R}{\partial C_2} = \sum_{i=1}^{NPNTSI} 2 \cdot \left[Y_i - (C_1 + C_2 \cdot X_i)\right] \cdot (-X_i)$$

Setting each expression to zero,

$$\sum_{i=1}^{NPNTSI} (Y_i - C_1 - C_2 \cdot X_i) = 0$$

$$\sum_{i=1}^{NPNTSI} (Y_i \cdot X_i - C_1 \cdot X_i - C_2 \cdot X_i^2) = 0$$

This gives two equations in which C_1 and C_2 are the only unknowns. Omitting the limits of summation for simplicity,

$$\sum C_1 + \sum C_2 X_i = \sum Y_i$$

$$\sum C_1 X_i + \sum C_2 X_i^2 = \sum Y_i \cdot X_i$$

or, in matrix notation (note that C_1 and C_2 are constants)

$$\begin{vmatrix} NPNTSI & \sum X_i \\ \sum X_i & \sum X_i^2 \end{vmatrix} \cdot \begin{vmatrix} C_1 \\ C_2 \end{vmatrix} = \begin{vmatrix} \sum Y_i \\ \sum Y_i X_i \end{vmatrix}$$

or

$$A \cdot C = B$$

The components of the matrix C are obtained using

$$a_{11} = NPNTSI$$

$$a_{12} = a_{21} = \sum X_i$$

$$a_{22} = \sum X_i^2$$

$$b_1 = \sum Y_i$$

$$b_2 = \sum Y_i \cdot X_i$$

$$C_1 = \frac{\begin{vmatrix} b_1 & a_{12} \\ b_2 & a_{22} \end{vmatrix}}{\begin{vmatrix} a_{11} & a_{12} \\ a_{12} & a_{22} \end{vmatrix}} = \frac{a_{22}b_1 - a_{12}b_2}{a_{11}a_{22} - a_{12}^2}$$

$$C_2 = \frac{a_{11}b_2 - a_{12}b_1}{a_{11}a_{22} - a_{12}^2}$$

$$C_1 = \frac{\sum X_i^2 \cdot \sum Y_i - \sum X_i \cdot \sum (Y_i\ X_i)}{NPNTSI \cdot \sum X_i^2 - (\sum X_i)^2}$$

$$C_2 = \frac{NPNTSI \cdot \sum (Y_i \cdot X_i) - \sum X_i \cdot \sum Y_i}{NPNTSI \cdot \sum X_i^2 - (\sum X_i)^2}$$
