SECTION A

LOCATION, TOPOGRAPHY, AND LOCAL EFFECTS

SECTION A
LOCATION, TOPOGRAPHY, AND LOCAL EFFECTS

1. Kadena AB is on the island of Okinawa, the largest island in the Ryukyus chain. The Ryukyus extend southwestward from Kyushu to Taiwan, forming the boundary between the Pacific Ocean and East China Sea.

2. The island of Okinawa is approximately 65 miles long and ranges from 2 to 15 miles wide. The northern two-thirds of the island consists of rugged hilly terrain. The average height of the hills is less than 1500 feet. The southern third of the island is less rugged, consisting of coral escarpment and small rolling hills. There are numerous small islands and coral reefs around the main island. Some of these, such as Ie Shima and the Kerama islands, are large enough to support small farming or fishing communities. The remainder are uninhabited.

3. Kadena Air Base, at 26 21'N 127 46'E and at a field elevation of 146 feet, is located just south of the central ridge of hills of northern Okinawa. There is a small plateau north-northwest of the base. "Radar hill", elevation 734 feet, is just to the north and Naha AB is visible to the south of the base. The East China Sea is just west of Kadena and the southwest runway approach (050) is over water. The approach from the northeast (230) is over four miles of small hills (under 300 feet) and farms. The base proper is 100 to 200 feet higher than the runway.

a. A Basic Weather Watch is conducted from the base weather station (BWS) at Kadena AB. At ground level, buildings obstruct 75 percent of the horizon leaving only the west through west-northwest area visible. Observers must climb three flights of stairs to view the entire horizon. Observations from this vantage point are fairly representative.

b. The weather and climatology of Ie Shima, a small island 26 miles northwest of the main island, are essentially the same as Kadena AB. The discussions and guidelines contained in this TFRN are also applicable to Ie Shima.

4. Data Availability.

a. Land weather observations near Kadena AB are relatively scarce. Only Kadena AB, Futenma MCAS, and Naha IAP take and report observations 24 hours per day. Seven other stations within 250 NM report hourly observations (METAR) during daytime hours. These are Ishigaki (ROIG, 47918), Miyako (ROMY, 47927), Shimoji (RORS), Kume Jima (ROKJ, 47929), Amami (RJKA, 47909), Erabu (RJKB, 47942), and Minami Daito (ROMD, 47945).

b. Naha, Amami, Ishigaki, and Minami Daito provide RAOB and PIBAL data.

c. In addition to radar observations taken at Kadena, reports (in RAOB code) are available from Ishigaki Miyako, Amami, and Naha/Itokazu (47937). Naha JASDF provides 3-hourly RAREPs at certain time of the year.

SECTION C

SYNOPTIC CLIMATOLOGY

SECTION C

SYNOPTIC CLIMATOLOGY

1. General. Okinawa experiences two principal seasons each year; summer and winter. The Kuroshio current which flows northward past Okinawa has a great influence on the climate of the island. Winters are mild and summers are warm and humid due to the ever present warm current. The weather of a particular summer or winter depends on the strength of two semi-permanent high cells, the Pacific high and the Siberian high. The polar front or polar trough divides these two air masses. Okinawa experiences southerly winds and maritime tropical air in the summer and northerly winds and continental polar (CP) air in the winter. The continental polar air is modified to a great extent due to the overwater trajectory it experiences before reaching Okinawa (this CP air must cross over the warm Kuroshio). Spring and fall are more variable in the type of weather conditions that occur and the length of the season each year, and they do not have the well defined characteristics of summer and winter. Often, upper air features are more critical to day to day forecasts than surface observations.

2. Winter. During winter the mean position of the polar front or trough is located south of Okinawa and the weather is dominated by the Siberian High. From January to March the daily weather follows a cyclic pattern of 3 to 8 days. The most significant features are trough or fronts which occur with outbreaks of the Siberian High. These develop in northern China and move rapidly southeastward to arrive at and strengthen the Polar trough (fig C-1). When these outbreaks are developing, Okinawa enjoys scattered low and high cloudiness and unrestricted visibility. These outbreaks are usually marked by gusty winds, towering cumulus, heavy showers, and occasional thunderstorms. The fronts usually cross the East China Sea with speeds up to 20 knots. Surface winds prior to the arrival of the front are light and southerly. Immediately before the outbreak arrives, winds may swing to the southwest or west. A wind shift to the northwest or north (often 30-40 Kts) occurs with the passage of the front and is the best indicator that a front has occurred. It is not uncommon to have brief occurrences of ceilings of 500 ft and low visibility in heavy rain at Kadena. Generally, light precipitation starts just prior to the frontal passage and continues for less than six hours, depending on the frontal movement. Arrival of the cold front at Kadena may be hard to detect because there often appears to be two cold fronts. There may be light

brief showers that give strong radar returns with the first wind shift. The wind, after the initial gusts, become light northerly. Four to six hours later heavy showers and persistent strong gusty winds will occur. Post-outbreak weather consists of one to three days of broken to overcast stratocumulus with bases at approximately 2000 ft and tops at 6000 ft. The sky is cloudless above this layer. These low ceilings persist until the strong northerly winds (25 to 35 kts) drop in intensity and swing to the northeast. Clearing then will take place with the sky conditions returning to low scattered and high broken cirrus. This cycle soon repeats itself.

3. Spring. Spring is a transition season. This period is also known as the "Rainy Season." However, the amount, intensity, and length of the season varies greatly from year to year. Usually the amount of rain during this period is not much greater than that of summer, but the occurrence of continuous periods of rain is much more frequent. As the polar front begins to move north, minor waves develop into large cyclones. Cyclogenesis often takes place off the Taiwan coast or in the Shanghai area (fig C-2). Light rain and drizzle with occasional heavy showers and thunderstorms will persist at Kadena for periods of from 6 to 36 hours with these systems. Low ceilings of stratus and fractocumulus and occasional frontal fog will accompany the rain. The weather during this period of the year can be the most difficult to forecast. During June, the rainy season reaches its peak intensity with heavy continuous rain occurring as the polar front fluctuates across Okinawa. By mid-June the front has moved north and will remain there until fall. During late spring a new forecast problem begins to occur. Early morning stratus may form on otherwise clear nights and persist until mid-morning. This layer of low (1000 ft) stratus is advected from south of Kadena and often arrives without warning. High relative humidity and southerly winds are necessary for the formation of this stratus, and pilot reports are the best source of information of its presence before it moves over Kadena.

4. Summer. Summer begins in late June when the polar front migrates to the north where it will remain until fall. The weather at Okinawa is maritime tropical in all respects. Winds are southerly and lighter than in winter, humidity is high, and most precipitation is of the showery type except during typhoons. Early morning stratus will still be a minor problem until July, but is not as persistent and with the rising temperatures of summer, soon ceases to occur. Afternoon rainshowers are the major problem. Convective cumulus build over the island around noon and reach the shower stage by early afternoon. The most likely area for development of these cumulus clouds is the hilly region north-northeast of Kadena. However, they are air mass cumulus and may develop at any location in the area. The problem is to determine whether these showers will move over the field or not. Ceilings in the showers will be near 1200 ft and the visibility 3 miles or less. Duration over the field is usually less than 20 minutes. Even with several showers in sight, prevailing visibility at Kadena will rarely drop below

5 miles. Occasionally, these showers may develop into thunderstorms but generally do not obtain typical thunderstorms characteristics even though their tops reach or exceed 30,000 feet. Summer shower activity is heaviest during the afternoon as would be expected. As the summer progresses it is common to see isolated anvil clouds along the horizon, with distant lightning visible at night. During late summer, showers are common around dawn, but are very light and brief.

5. Typhoon Season. The typhoon season for Okinawa begins in late May and lasts through November. The peak months of the season are August and September. Weather in the "average" typhoon begins with light to moderate shower activity as the storm approaches. Towering cumulus and isolated cumulonimbus are common, as is a shield of cirrostratus. Nearer the center, moderate to heavy intermittent rain and heavy showers occur. Ceilings vary from 200 to 2000 feet and visibility from $\frac{1}{2}$ to 5 miles (fig C-3). Near the eye of the storm, rain and blowing spray are mixed by the high winds.

6. Fall. In late September the polar front again moves back into the local area. During the fall it moves south rapidly as opposed to its slow northward movement during spring. Frontal passages are usually brief with four to six hours of light rain or drizzle. Heavy thunderstorm activity is rare. Skies clear rapidly after frontal passage, leaving scattered low and middle cloudiness with thin broken to overcast cirrus. The polar front when south of Kadena, is weak and may not have any well defined frontal characteristics. Okinawa enjoys a modified continental polar air mass which brings the best flying weather of the entire year during early fall. Typhoons occasionally threaten Okinawa until December and any extended period of low ceilings and visibility is usually associated with a tropical disturbance. Afternoon and evening towering cumulus may still form, but are isolated. Precipitation is light. This season might be called the "dry season" for Kadena other than for the infrequent tropical cyclones that raise the mean monthly precipitation totals. Surface winds are predominately out of the north and the mean speed is the highest of the year. Fall type weather continues until the Siberian High intensifies to the point where cold outbreaks begin to occur, usually in December or January.

CLIMATOLOGICAL DATA

CLIMATIC OUTLOOK FOR JANUARY

During the month of January the Polar Front is situated well south of Okinawa over the Northern Luzon area. Okinawa's weather is dominated by the Siberian High Pressure cell over Mongolia. Cold weather "out-breaks" developing from the Siberian High are generally modified when they reach the warm waters of the East China Sea. therefore Okinawa's daily minimum temperature rarely drops below 45°F. Occasionally low pressure cells develop just south of Shanghai on the China Coast and move in an East-northeasterly direction just north of Okinawa bringing low clouds, light precipitation, and gusty surface winds to the area. Sea water temperatures average 72°F and the air temperature 61°F. The contrast between these two temperatures cause low level clouds (average 3,000') and light rain-showers to develop over or near the Island.

P CLIMATIC OUTLOOK FOR FEBRUARY

As winter weather continues over Okinawa, the month of February shows that the Polar Front has reached its southern most position some 500 miles south of the Island. During the month the Siberian high reaches its maximum intensity and the daily weather follows a cyclic pattern of approximately every 3 to 8 days. Precipitation continues to be associated with cold air (warm water) stratocumulas, frontal passages, and low pressure waves that form on frontal systems after they pass Okinawa. Occasional low pressure cells that form over or near Taiwan (Taiwan lows) are also an important influence on the weather over Okinawa during February, as their favorite trajectory begins northeastward along the polar front and east of Okinawa.

C. CLIMATIC OUTLOOK FOR MARCH

During March the Polar front begins its annual retreat northward and is situated between Luzon and Tiawan. The Siberian high starts to weaken quite rapidly and move northward. Frequent low pressure cells develop in the vicinity of Shanghai China and track toward the northeast. Cold frontal systems associated with the Shanghai lows occasionally pass through Okinawa. Low pressure cells also develop in the vicinity of Tiawan and track northeastward into the Okinawa region. Occasional low clouds, gusty surface winds and rain occur over Okinawa due to the passage of the Tiawan low and the frontal systems associated with the development of the Shanghai low.

Average freezing level-----10,000'

D. CLIMATIC OUTLOOK FOR APRIL

During April the Siberian high pressure cell has lost its energy and no longer becomes a cold and windy weather threat to Okinawa. Polar frontal passages are few and become quasi-stationary some 120 miles south of the island. Monthly precipitation increases from 4.8 inches in March to 6.1 inches in April due to the irregular position of the polar front and the occasional low pressure cells that develop along the front and pass near the island of Okinawa.

SKY CONDITION

E. CLIMATIC OUTLOOK FOR MAY

During May the polar front is located in the vicinity of Okinawa and the onset of Okinawa's rainy season begins. Low pressure cells that develop along the polar front move through Okinawa at an average of one every four days, periods of light to moderate rain and low ceilings occur nearly each day during the rainy season. Cloud ceilings less than 1000 feet and visibility less than 2 miles occur at least 10% of the time during the month. The average air temperature is a humid 75°F and the average sea temperature jumps to 77°F. The rainy season usually lasts well into the month of June on Okinawa.

SKY CONDITION

Average cloud cover	7.8 tenths
Frequency of VFR conditions	68.3%

F. CLIMATIC OUTLOOK FOR JUNE

June is the most unique month of the year as it marks the end of rainy season on Okinawa and the beginning of the Tropical cyclone season. During the month of June the Polar front continues its northward migration and assumes a mean position approximately 180 miles north of Okinawa. The rainy season continues for the first half of the month while the second half is dominated by the hot humid weather of summer. The probability of a Tropical cyclone affecting Okinawa during June is about 30%. June's Tropical cyclones usually form between Guam and the Phillipines and recurve to the north just east of Luzon affecting Taiwan, Okinawa or Southern Japan before dissipation.

SKY CONDITION

Average cloud cover	8.0 tenths

------------------------	---------

G. CLIMATIC OUTLOOK FOR JULY

During July the Polar front has reached its summer position and is orientated east to west from mainland China, across the lower Yellow sea, through central Korea and into central Japan. It is during this month that mainland Japan has its rainy season. the Pacific high pressure cell is well developed over Okinawa and with its arrival comes the hot, humid weather which is predominant during the summer months on Okinawa. Tropical Cyclones during the Month of July usually form south of Guam and approximately 45% of these storms recurve toward Okinawa. There is a 35% chance that Okinawa will be affected by a Tropical Cyclone during the month.

SKY CONDITION

*** 23 July 1949 from Typhoon GLORIA. Eye passed 25NM southwest of Okinawa.

H. CLIMATIC OUTLOOK FOR AUGUST

August finds Okinawa completely under the influence of the Pacific High Pressure Cell and its associated southwest summer monsoon. The Inter-tropical convergence zone (ITCZ) migrates to its northern most position during August and is situated over the southern Luzon area. The combined influence of these systems make August the hottest month of the year on Okinawa. Tropical Cyclones that for during the month of August move toward the west to westnorthwest and generally recurve toward the northeast near Okinawa. There is a 40% chance that Okinawa will be affected by a Tropical Cyclone during the month of August. August is the peak month for Tropical Cyclone threats on Okinawa.

SKY CONDITION

Average cloud cover	5.2 tenths

*** 15 August 1954 from Typhoon GRACE. Eye passed overhead on Okinawa.

I. CLIMATIC OUTLOOK FOR SEPTEMBER

September marks the last of the hot months on Okinawa and is also the transition month from the southwest monsoon of summer to the northeast monsoon of winter. By the end of the month the polar front should have reached a position just south of Okinawa. September is second only to August as the month with the greatest percentage probability of a Tropical Cyclone hit, about 40%. As a matter of interest, the most severe Tropical Cyclone recorded in recent times on Okinawa was Tropical Cyclone "EMMA" which struck the Island during September of 1956. The Ryukyuan Meteorological Agency registered sustained winds of 100 knots during "EMMA" with a peak gust of 143 knots.

SKY CONDITION

* 8 September 1956 from Typhoon "EMMA". Typhoon "EMMA" passed over Okinawa dumping 42.2 inches of rain in a 24 hour period at Kadena Air Base. Max gust of 143 knots was recorded at the Ryukyu Weather Bureau Observatory at Naha, Naha air base recorded peak gust of 112 knots while Kadena Air Base recorded 100 knots.

CLIMATIC OUTLOOK FOR OCTOBER

The month of October offers welcome relief from the summer heat of June through September. The Polar front lies south of Okinawa and Taiwan and the cooling northeast wind flow originating over central Asia and dominating the local weather picture, causes lower temperatures, humidity and precipitation over the local area. There are however, two sources of adverse weather which can have a marked effect on Okinawa during October and they are: (1) Tropical Cyclones which remain a threat to Okinawa with a 32% probability of a hit and: (2) Taiwan lows which were covered in February's climatic outlook.

K. CLIMATIC OUTLOOK FOR NOVEMBER

During the month of November, the Siberian High pressure cell continues to build over central Asia, bringing the first snow to Northern Japan and pushing the Polar front further south toward its mean winter position across Northern Luzon Island in the northern Phillippines. The front is still relatively weak and stable during November with little low pressure wave action. Okinawa can expect from 4 to 8 frontal passages during the month with accompanying shower activity and isolated thunderstorms. The primary feature of these frontal passages is the strong northerly winds that normally follow the actual frontal passage. These winds which occasionally gusts from 25 to 35 knots, usually prevail for periods up to 48 hours. Tropical Cyclones occur during November with a hit probability of 25% for Okinawa.

SKY CONDITION

K. CLIMATIC OUTLOOK FOR DECEMBER

During the month of December, the Polar front has reached the southern limits of its seasonal migration. The front lies east/west across Laos, North Viet Nam and Northern Luzon in the Philippines. With the Siberian High Pressure Cell dominating the local weather, prevailing winds are out of the north quadrants causing temperatures to remain mild and relative humidity to remain below the yearly average of 79%. Most of the cloudiness in the Okinawa region during December is of the stratocumulus type due to the flow of cold air from Mongolia transported over the warmer waters of the Western Pacific Ocean. This cold air is modified in the lower layers by the warmer waters which in turn produces a shallow layer of stratocumulus behind the front. Typhoons are not a threat to Okinawa during December.
