FOREWORD

United Technologies Corporation, Pratt & Whitney Aircraft Group, Government Products Division prepared this document for the Air Force Aero Propulsion Laboratory to meet the requirements of a User's Manual under Contract F33615-79-C-2013, Research on Software for Optimization of Vane and Bleed Settings in Multi-Stage Axial Compressors. This document complies with the Contract Statement of Work Item 5.0. The work described in this report was performed during the period 15 May 1979 to 15 May 1981. Efren Strain (1/Lt, USAF) is the Air Force Program Manager.

SECTION I

INTRODUCTION

Gas turbine engines for jet aircraft must maintain high performance over a wide range of flight conditions. Thus, many of the components in these engines incorporate variable-geometry configurations and bleed systems to meet the requirements of changing environments. The fan and compressor normally contain a combination of variable vane rows and bleeds to accomplish this objective. Hence, optimization of variable vanes and bleeds or selection of the best vane and bleed schedule plays a very important role in compression system development. During initial development, most compressors are built with all vane rows variable, even though only a few rows may be variable in the final design configuration. Optimization objectives vary from configuration to configuration. However, typical examples of parameters requiring optimization include overall efficiency, surge margin, airflow, and pressure ratio.

Current optimization techniques generally consist of running a matrix of test points with various geometry settings, shutting down the test article, reviewing the interstage aerodynamics, selecting a new series of test points using engineering judgement, and further diagnostic testing. This process is very time-consuming and expensive and rarely achieves a true optimum.

Compressor test facilities are often linked to large computers for online data feedback. Experience in compressor development and system simulation indicates that utilizing a software package through a logical series of iterations could guide decisions of the test engineer and, thus, reduce the number of data points and test time required to achieve an optimum performance goal. Ultimately, a system could conceivably be used to control the search for optimum performance. This contract effort developed a computer program in FORTRAN IV language capable of guiding the optimization of vane and bleed settings in multi-stage axial compressors.

The technical approach to the development of software for optimization of vane and bleed settings in multi-stage axial compressors involved definition of optimization goals, development of the performance-seeking logic, creation of a computer program to complement the logic, and demonstration of the function of the software.

This user's manual describes the vane and bleed optimization computer program (Customer Computer Deck CCD 1182). The program includes the capacity of handling four variable vanes and one bleed. The basic goal-seeking algorithm is the COPES/CONMIN approximate optimization method described in Reference 1. The program includes a stage-by-stage compressor model that simulates an eleven-stage, four variable-vane compressor to demonstrate program capabilities. This document presents sample problems using the compressor simulation to help the user become familiar with the program deck.

SECTION II

PROGRAM DESCRIPTION

Computer program CCD 1182-0.0, developed on an IBM 3033 computer, is a FORTRAN program capable of guiding the optimization of vane and bleed settings in multi-stage axial compressors. Operated through an iterative terminal, the computer program is designed to be used in a manual mode with real-time data reduction. Inputs include the optimization goal, vane and bleed setting limits (e.g., ± 10 deg about the base vane setting), vane and bleed initial settings, performance constraints, and compressor rig measurements of overall performance. The main element of the computer program consists of the COPES/CONMIN approximate optimization algorithm that provides the test engineer with information required for the next vane or bleed setting. Flow charts showing program logic appear in Figures 1 and 2

The vane optimization program primarily performs an information management task. The program supplies the computer terminal with several successive information displays based on stored data. The operator initially selects one of seventeen optimization goals summarized on the display screen. This display alone is sufficient to describe required operator actions and specific test goals.

The operator will then be prompted for the number of variable vanes and bleeds (N) to be optimized, upper and lower bounds for vane angle and bleed flow, and the size of the incremental vane and bleed variation used for the first N+1 test points. At this point, the program will tell the operator to run the base condition from which the optimization will begin. The operator is then prompted for the vane and bleed settings, and performance index (and constraint values, if applicable). The performance index and constraint values are defined based on the optimization goal selected. These may be efficiency, stall margin, corrected flow, or pressure ratio, all of which are available from the compressor test facility. The first basis vane angle and bleed perturbations are calculated and returned to the operator. The performance index and constraint values are input to the terminal. Additional basis vane angle and bleed perturbation cases are run until N+1 test points are run. The points run provide an initial model of the performance index function. After the performance index model is created, multiple optimization passes are made using this approximate design model. The approximated optimum vane and bleed settings (as determined by this pass) are sent to the operator. During the setting of new conditions, the operator monitors for external constraints, such as flutter or blade strain. If and when these limits are reached, the performance index may be modified to account for an aeromechanical constraint boundary. A convergence check and test for maximum iterations is made. The program control will return to COPES/CONMIN with the new data point. The COPES performance index model is updated and a new optimization iteration proceeds.

Following a convergence at the optimum, a description of the convergence criteria will be displayed and a complete documentation of the optimization path will be printed. The following paragraphs describe the program elements in detail.

INITIALIZATION

Data initialization occurs in two ways: through block data and through operator input. Block data is used to initialize the data which generally does not change from one test case to another. The optimization program will ask the operator for any further information required to complete the initialization for a given test case.

Figure 1. Vane Optimization Logic

FD 210267

Figure 2. COPES/CONMIN Approximate Optimization Interface

COMPUTER TERMINAL DISPLAYS

The program title page, shown in Figure 3, will be automatically displayed on the terminal once the program has been loaded into the computer and the program is operational. Once the user initiates the program operation, a list of optimization goals will appear on the terminal for selection of the specific goal desired. A sample of the second display appears in Figure 4. Following selection of the desired goal, the interactive terminal will display the choice for verification. Typical versions of this display are shown in Figures 5 and 6.

The displays that follow on the terminal perform four functions, as described below:

1. Generate reminders of compressor operating conditions which may need to be held during the optimization process
2. Set upper and lower bounds for vane settings and performance constraints
3. Define the starting sequence of the test
4. Prompt the operator to make certain vane movements and perform efficiency and/or stall margin calculations.

Data entry displays will always repeat the entered information and await an accuracy approval or a correction command. Figures 7 through 16 show examples of how these functions are performed.

DATA STORAGE (ERROR RECOVERY)

The internal logic of COPES/CONMIM is incapable of "backing out" the previous input data if an error has been incurred. To minimize errors, the terminal input data, as interpreted by the computer, is redisplayed for verification prior to being stored. If an error is still made, a complete restart of the optimization logic is required. However, the compressor (or compressor model) need not be rerun. The computer program is reinitialized by the statement RFLAG=1. and the data values are re-entered exactly as they were originally input. Operator prompting will continue as during normal operation.

STARTING SEQUENCE OF TESTS

The basic aim of the COPES/CONMIM approximate optimization is to optimize an approximate surface by Taylor series expansion. To provide an initial model of this surface, a sequence of tests is performed wherein each vane and bleed setting is randomly varied. The minimum number of tests is $N+1$. Figure 17 presents the suggested starting sequence for up to four variable vanes and one bleed. Incremental vane and bleed settings are an operator input and may be chosen based on the expected performance sensitivity to vane angle. For high stage-loading compressors, a value between ± 1 and ± 2 deg is suggested. Note that to reduce experimental error, vanes are not reset between tests in this sequence.

FD 210282

Figure 17. Initial Test Sequence

OPERATOR-IMPOSED CONSTRAINTS

During a test program, the operator will be monitoring a variety of strain gauge and blade flutter monitors. Any of these sensors may allow the operator to conclude that the test point vane settings may threaten the mechanical integrity of the compressor. Rejection of a test point should not automatically bring about the conclusion of the optimization attempts. The way to avoid this vane setting region (and discourage further movement in the hazardous direction) is by the artificial creation of a performance index deterioration or a constraint variable rise. A series of such actions by the operator will define to the program a wall or barrier that should not be crossed due to the optimum-seeking or constraint-avoidance logic. The technique employed in the vane optimization program is to change the performance index of the hazardous point by a factor of two. This is enacted by indicating that flutter or excessive vibration has occurred at the requested point.

STOPPING POINT

The stopping criteria used in this program include:

1. A minimum relative change in the objective function to indicate convergence
2. An absolute change in the objective function
3. A maximum number of iterations
4. Two consecutive approximate optimizations resulting in the same vane angle settings.

SECTION III

PROGRAM ORGANIZATION

GENERAL

The main program, as shown in Figure 18, consists simply of calls to the various subroutines used to initialize the input into the COPES/CONMIN optimization subroutine known as VOPT. Additionally, the main program contains logic for restarting the program at any point during the optimization. A description of each subroutine appears in the following paragraphs.

Subroutine PAGE1

Subroutine PAGE1 writes the title page to the screen and to the printer. The subroutine then waits until the operator depresses ENTER to go to subroutine GOAL.

Subroutine GOAL

Subroutine GOAL displays the listing of optimization goals and asks the operator to enter the value of the desired goal. It should be noted here that the value of the desired goal should be right adjusted in a two-column field. This means that numbers 1 through 9 should be entered as 01 through 09. Subroutine GOAL then writes to the screen the goal which the operator selected. When the operator is satisfied with the goal he has selected, subroutine GOAL then returns to the main program with the value of the desired goal.

Subroutine OPTCON

Subroutine OPTCON takes the value of the desired goal and prompts the operator for the necessary input to be used to write the COPES/CONMIN program input data.

Subroutine START

Subroutine START takes the initial X-vector and the number of design variables (NDV) and then creates NDV+1 X-vectors by perturbing the vane angles and bleed flow by some given amounts input by the operator. The subroutine writes these vectors into a file that will be read by COPES/CONMIN.

Subroutine SCFILE

Subroutine SCFILE takes all of the block data and all of the input from subroutine OPTCON and writes it into a file in right-adjusted fields of 10 columns each. COPES/CONMIN then reads this file in its optimization process.

Subroutine VOPT

Subroutine VOPT is the COPES/CONMIN optimization program.

FD 210258

Figure 18. Program Organization

Subroutine ANALIZ

The COPES User's Manual (Reference 1) explains subroutine ANALIZ. An additional feature has been added to the usual ANALIZ output. When the program reaches a final solution, ANALIZ will write out the final results on the screen for the operator to see.

Subroutine ANALIZ includes a restart signal enabling the operator to restart the program without re-entering the data through subroutine OPTCON.

INITIALIZING INPUT-OUTPUT FILES

Before executing the vane optimization program, the user must allocate the following files:

<u>File No.</u>	<u>Program Name</u>	<u>Use</u>
5	ISCRX	Contains initial NDV+1 X-vectors
5	ISCRXF	Contains X-F pairs on a continuous basis
6	IPRINT	Output to printer
11	ISC	Scratch file which contains COPES/ CONMIN input data
12	ISCR1	Scratch file used by COPES/CONMIN program
13	ISCR2	Scratch file used by COPES/CONMIN program
15	IREAD	Input from terminal
16	IWRITE	Output from terminal

All files, except File 13 (ISCR2) should contain the following attributes: Block size — 6160, logical record length — 80, and record format — fixed block. File 13 should contain the following: block size — 6160, logical record length — 85, and record format — variable block span. Figure 19 shows a sample procedure for initializing these input-output files.

SECTION IV

COPEs/CONMIN DESCRIPTION

THEORY

CONMIN (Reference 2) represents a general purpose optimization program designed primarily for the optimization of constrained functions. The basic optimization algorithm used in CONMIN employs a direct search technique based on the method of feasible directions described in Reference 3. The algorithm has been modified to improve efficiency and numerical stability and to solve optimization problems in which one or more constraints are initially violated (Reference 4). In a subroutine format, CONMIN can be called by a user-supplied main program. The user should supply a main program containing the analysis, constraints, equations, and objective function. Therefore, if an existing analysis program is used, the analysis portion may need some reorganization, and constraint equations must be prepared in accordance with CONMIN requirements.

In order to eliminate this inconvenience, a control program known as COPEs (a FORTRAN Control Program for Engineering Synthesis) was developed by the same author who developed CONMIN. COPEs combined with CONMIN enables the use of CONMIN as a "black box" for optimization in automated design synthesis. The user need only provide a FORTRAN analysis program for the particular problem being considered. COPEs simply calls the user-supplied program written according to a simple set of guidelines. The capabilities of COPEs/CONMIN include:

1. Simple analysis
2. Optimization
3. Sensitivity analysis
4. Two-variable function space generation
5. Optimum sensitivity analysis
6. Approximate optimization.

Particularly, approximate optimization provides the most suitable technique for the compressor vane optimization problem where the number of test points needed to perform the optimization is a limiting factor. The basic idea of approximate optimization technique involves sequentially optimizing an approximate design function surface generated from available information. In this program, the design surface represents a function of efficiency and stall margin. At the end of the optimization, the design surface is updated with information from a precise analysis, or test, at a new set of design variables. This new approximate problem is then optimized, followed by a new precise analysis. This process repeats until the solution has converged.

COPEs/CONMIN possesses the capability to do up to a second-order approximation. If excessive data are available, the extra data are applied to a weighted least-square fit, rather than in obtaining higher order approximations. If a quadratic design surface were assumed, the second-order approximation would be precise. If the problem at hand can be approximated by a quadratic function, this method becomes feasible.

An outline of the sequential approximation approach (Reference 5) appears below. The second-order approximate form comes from a Taylor series expansion of any function, noted as

$$\Delta f \approx \nabla f \cdot \Delta \bar{x} + \frac{1}{2} \Delta \bar{x}^T [H] \Delta \bar{x} \quad (1)$$

where,

$$\Delta \bar{x} = \bar{x} - \bar{x}^0$$

$$\Delta f = f - f^0$$

$$\bar{\nabla} f = \left[\frac{\partial f}{\partial x_1} \frac{\partial f}{\partial x_2} \dots \frac{\partial f}{\partial x_n} \right]^T$$

$$[H] = \begin{bmatrix} \frac{\partial^2 f}{\partial x_1^2} & \frac{\partial^2 f}{\partial x_1 \partial x_2} & \dots & \frac{\partial^2 f}{\partial x_1 \partial x_n} \\ & \frac{\partial^2 f}{\partial x_2^2} & & \\ & & \dots & \\ \text{Symmetric} & & & \frac{\partial^2 f}{\partial x_n^2} \end{bmatrix} \quad (2)$$

n = number of design parameters

x^0 = nominal design analyzed to yield f^0 .

Equation 1 holds for both objective and constraints. The unknowns are:

$$\frac{\partial f}{\partial x_1} \dots \frac{\partial f}{\partial x_n} \text{ and } \frac{\partial^2 f}{\partial x_1^2} \dots \frac{\partial^2 f}{\partial x_n^2}$$

for a total of $(\ell = n + n(n+1)/2)$. Since one analysis is required for the nominal design, a total of $(\ell+1)$ test points are required to determine the unknowns, $(\bar{\nabla} f)$ and $[H]$. If more than $(\ell+1)$ tests are available, a weighted least-square fit is used.

Since previous test data show that efficiency and stall margin can be closely approximated locally in quadratic form in terms of the vane angle, quadratic approximation in the compressor vane optimization is considered quite reasonable. The fact that analysis data obtained in one optimization are used to improve the design surface for subsequent optimization enables the test engineer to choose a new test point; i.e., the result obtained in one optimization becomes the recommended test point and the test result obtained at this point is added to the new approximate optimization problem.

Numerical experience shows that a full quadratic approximation is not necessarily required even when the design function surface is quadratic. An approximation that includes up to the diagonal terms of the Hessian matrix in Equation 1 is quite accurate for a quadratic surface. This approximation requires a minimum of $2n+1$ test points (n tests for linear terms, n tests for diagonal terms of the Hessian matrix, and one test for the initial design point). If more than $2n+1$ designs are available, they are used in a weighted least-square fit. The COPES/CONMIN program provides the user with the option to use the approximate design surface constructed using only up to the Hessian diagonal terms in the approximate optimization. Because this technique can significantly reduce the number of expensive test points without losing the quality of the solution, it is used in the compressor vane optimization.

INTERFACING REQUIREMENTS

The COPES/CONMIN computer program is set up to make multiple passes through a subroutine called ANALIZ. In the conventional design process, this subroutine will contain an evaluation of the performance index being optimized and the constraint parameter for a given set of vane angles. The vane optimization program logic will specify a new vane setting to the operator and take care of recording new data from operator entries in the proper format. Command will be transferred back to the program and execution will continue with the newly supplied information. The method of interfacing described above required the absolute minimum level of COPES/CONMIN code change.

Another very important interfacing objective is to reformat operator input data to be compatible with the existing COPES input handling routine COPE01. Again, the driving force behind this objective is the desire to retain as much of the original COPES code as possible.

The COPES User's Manual (Reference 1) contains a detailed description of the complete input file requirements for the full variety of deck options. Figure 20 presents a listing of the card images of input data relevant to the COPES/CONMIN approximate optimization logic within the compressor vane optimization program.

Figure 20. COPES/CONMIN Input Data Relevant to the Compressor Vane Optimization Program

SECTION V

PROGRAM DEMONSTRATION

COMPRESSOR SIMULATION

In order to demonstrate the vane optimization software, a stage-by-stage compressor model has been implemented into a computer program. The characteristics of normalized pressure rise and temperature rise as functions of normalized airflow and vane angle are representative of an eleven stage, four variable vane compressor. The stall line used to provide the compressor performance appears in Figure 21. The illustrations shown in Figures 22 through 25 depict the efficiency and stall margin variations with vane angle computed at two degree increments, while holding speed and discharge area constant.

It should be noted that efficiency and stall margin calculations have an accuracy of $\pm 0.05\%$, which may be attributed to the following factors:

1. Stage characteristic modeling
2. Interpolations between stage characteristics
3. Flow balance iterations.

Thus, the performance calculations from this model can be considered to have an inherent $\pm 0.05\%$ measurement error.

Input to the stage-by-stage compressor model is read using a FORTRAN-NAMELIST statement. Each input case must begin with \$PWA punched starting in Column 2 to prepare the program to read the input. The input then follows, punched in FORTRAN-NAMELIST format, with each item separated with a comma and with the input list concluded by \$END. No input may be entered in Column 1. The \$END card initiates execution. The input parameters are as follows:

<u>Parameter</u>	<u>Default Value</u>	<u>Description</u>
NIN	5	Input file number
NOUT	6	Output file number
NOUTN	0	Optional output file number
CASE*	0	Case number
VANE1	0	Vane angle 1
VANE2	0	Vane angle 2
VANE3	0	Vane angle 3
VANE4	0	Vane angle 4
STOP	0	Stop signal
WCINLT	Converged	81.5 Inlet corrected airflow
GUES	values from previous case	
	or	0.94 M-line guess

The converged values for the independent variables WCINLT and GUES from a successfully closed point can be used as guesses for the next point. If no guess is supplied by the user for the first run, the values 81.5 and 0.94 will be used as guesses for WCINLT and GUES, respectively. On succeeding points, if no guesses are given, the converged values from the last point are used. The M-line guess should be approximately 1.0.

*CASE is automatically incremented with each set of input read, unless reloaded.

FD 181297

Figure 24. Efficiency and Stall Margin Variation With Variable Vane 3

FD 181298

Figure 25. Efficiency and Stall Margin Variation With Variable Vane 4

All input is initially read and written to input files 5 and 6. However, the file number can be changed by the user by changing the input variables NIN and NOUT. It is also possible to direct the output to two different output files by specifying another file number NOUTN. If this variable is omitted, output will be directed to only one file, specified by NOUT. A STOP = -1.0 should be included in the last input case to terminate the program. If it is left out or set to a value other than -1.0, the program will look for another input case to follow. The output parameters are:

<u>Parameter</u>	<u>Description</u>
VANE1	Input vane angle 1
VANE2	Input vane angle 2
VANE3	Input vane angle 3
VANE4	Input vane angle 4
SM	Surge margin
EFF	Adiabatic efficiency
PR	Pressure ratio
WC	Corrected airflow

The following paragraphs detail the results for various optimization goals using the optimization program on the stage-by-stage compressor simulation. A summary of the problems solved and the resulting solutions is presented in Table 1. Appendices A through I contain output information for the sample problems.

UNCONSTRAINED OPTIMIZATION

Example 1:

The objective of this problem involves the optimization of four variable vanes for maximum efficiency, while holding speed and discharge area constant (Optimization Goal 1). The optimization problem can be formulated as

$$\begin{aligned} \max \quad & \eta(\alpha_1, \alpha_2, \alpha_3, \alpha_4, N, \text{AREA}) \\ \text{subject to} \quad & \alpha_1, \alpha_2, \alpha_3, \alpha_4, N, \text{AREA} \end{aligned} \quad (3)$$

subject to

- a. $\alpha_{1\min} \leq \alpha_1 \leq \alpha_{1\max}$ $\alpha_{2\min} \leq \alpha_2 \leq \alpha_{2\max}$
 $\alpha_{3\min} \leq \alpha_3 \leq \alpha_{3\max}$ $\alpha_{4\min} \leq \alpha_4 \leq \alpha_{4\max}$
- b. $\text{AREA} = \text{AREA}_0 = 76.779$
- c. $N = N_0 = 5567.5 \text{ rpm } (\%N_c = 85)$

The upper and lower bounds imposed on vane travel appear in Table 2.

With initial vane settings of $(\alpha)_1=29$ deg, $(\alpha)_2=18$ deg, $(\alpha)_3=15$ deg, and $(\alpha)_4=11$ deg, and initial efficiency of 87.14%, convergence to the optimum efficiency of 87.53% occurs in 15 tests (10 iterations). Optimum vane angle settings become $(\alpha)_1=25.59$ deg, $(\alpha)_2=17.99$ deg, $(\alpha)_3=12.17$ deg, and $(\alpha)_4=7.47$ deg. Note that the incremental vane angle variation used for the initial sequence of 5 tests is -2 deg. Appendix A details the optimization results for Example 1.

Lower Bound	10	5	5	5
Upper Bound	35	25	25	25

Example 2:

This problem duplicates Example 1, except that the initial sequence is modified. Design of the example evaluates the effect of randomly selecting the initial test points.

With initial vane angles set at $(\alpha)_1=18$ deg, $(\alpha)_2=10$ deg, $(\alpha)_3=5$ deg, and $(\alpha)_4=5$ deg, and efficiency $(\eta) = 86.60\%$, convergence occurs in 19 tests, although optimization was reached at the fifteenth test point. Optimum vane angles become $(\alpha)_1=24.55$ deg, $(\alpha)_2=17.78$ deg, $(\alpha)_3=11.68$ deg, and $(\alpha)_4=7.76$ deg at an efficiency of 87.52%. A 2 deg incremental vane angle variation was used for the initial sequence of tests in this example. Appendix B lists the optimization results for Example 2.

The fact that the optimum efficiency duplicates that found in the first example indicates that the analysis is relatively insensitive to starting point. The optimum vane angle settings, however, are slightly different for the two examples, although they are within 1 deg of each other. The compressor model exhibits a very flat region near the optimum with little gain in efficiency. This fact also attributed to the additional tests required in the second example to meet the convergence criteria after the optimum was reached.

Example 3:

The objective of Example 3 is to maximize stall margin while holding speed and discharge area constant (Optimization Goal 7). The problem can be expressed as

$$\begin{aligned} &\max \text{ SM} \\ &\alpha_1, \alpha_2, \alpha_3, \alpha_4 \end{aligned} \quad (4)$$

With the same initial vane settings and initial test sequence as in Example 1, the optimum settings were obtained after 22 test points. The vane settings are $(\alpha)_1=18.94$ deg, $(\alpha)_2=10.71$ deg, $(\alpha)_3=5.00$ deg, and $(\alpha)_4=5.00$ deg with an optimum stall margin at 10.30%. The efficiency at these vane settings is 86.73%. Results for this problem appear in Appendix C.

CONSTRAINED OPTIMIZATION

Example 4:

The function maximized in Examples 1 and 2 is now solved with stall margin constrained above a given level (Optimization Goal 4). The stall margin at the optimum efficiency conditions in the previous examples are 9.32 and 9.45%, respectively. Mathematically, this problem can be stated as

$$\begin{aligned} &\max \eta \text{ subject to } \text{SM} \geq 10.0\% \\ &\alpha_1, \alpha_2, \alpha_3, \alpha_4 \end{aligned} \quad (5)$$

With the same initial vane settings and initial test conditions as Example 1, a converged solution results in 14 tests at $(\alpha)_1=23.73$ deg, $(\alpha)_2=15.58$ deg, $(\alpha)_3=7.29$ deg, and $(\alpha)_4=5.37$ deg with an efficiency at 87.39% and stall margin of 10.00%. Note that the optimization algorithm brought the efficiency down from the 87.5% values in Examples 1 and 2 to meet the stall margin constraint. Appendix D presents the results for this example.

Example 5:

The same problem as Example 4 is considered, except that the influence of measurement error on convergence ability is examined. In addition to the $\pm 0.05\%$ noise in the stage-by-stage model, the random errors shown in Table 3 are added to the performance values. The errors are normally distributed with a standard deviation of 0.05.

Appendix E details the results for this example. The optimum was reached in 15 tests at $(\alpha)_1=22.64$ deg, $(\alpha)_2=14.72$ deg, $(\alpha)_3=9.24$ deg, and $(\alpha)_4=5.00$ deg with efficiency at 87.38% and stall margin at 9.98%. The efficiency and stall margin are essentially the same as the values obtained in Example 4 and the vane angles are within 2.0 deg.

Example 6:

This problem represents the constrained version of Example 3. Here, it is desired to maximize stall margin while maintaining efficiency above a given level (Optimization Goal 10). Mathematically, this can be represented as

$$\begin{aligned} &\max \text{ SM subject to } \eta \geq 87.3\% \\ &\alpha_1, \alpha_2, \alpha_3, \alpha_4 \end{aligned} \quad (6)$$

Appendix F details the results of this optimization with start settings for vane angle as in Example 3. The optimum solution was reached after 21 tests at vane settings of $(\alpha)_1=22.34$ deg, $(\alpha)_2=14.54$ deg, $(\alpha)_3=8.87$ deg, and $(\alpha)_4=5.00$ deg with an optimum stall margin of 10.09% and an efficiency of 87.32%. Here, the optimization algorithm brought the stall margin down from 10.30% obtained in Example 3 to meet the efficiency constraint.

TABLE 3. MEASUREMENT ERRORS FOR EXAMPLE 5

Test Point Number	Efficiency Error (%)	Stall Margin Error (%)
1	0.04	-0.04
2	-0.02	0.04
3	-0.03	0.09
4	0.03	-0.02
5	0.09	0.06
6	-0.02	-0.08

19	-0.04	-0.06
20	0.05	-0.05
21	0.08	0.03
22	-0.03	0.04

Example 7:

The next two examples establish the maximum and minimum flow points to provide the maximum flow range. In addition to airflow requirements, performance constraints of minimum acceptable efficiency and stall margin also define the flow range. Thus, their evaluations must be considered for each geometry setting. For this example, Optimization Goal 14 is defined as

$$\max_{\alpha_1, \alpha_2, \alpha_3, \alpha_4} W_c \quad \text{with } \eta \geq 87.0\% \text{ and } SM \geq 8.5\% \quad (7)$$

subject to the conditions of holding speed constant at 5567.5 rpm and discharge valve area at 76.779.

Appendix G details the results. For the initial test sequence used in Examples 1 and 3 through 6, the optimization algorithm converged to the maximum flow in 14 tests at a corrected flow of 84.39 lbm/sec with an efficiency of 86.81% and stall margin of 10.19%. Optimum vane settings are $(\alpha)_1=20.08$ deg, $(\alpha)_2=10.31$ deg, $(\alpha)_3=5.85$ deg, and $(\alpha)_4=5.00$ deg.

Example 8:

This example deals with minimizing corrected airflow (Optimization Goal 15), mathematically formulated as

$$\min_{\alpha_1, \alpha_2, \alpha_3, \alpha_4} Wc \quad \text{with } \eta \geq 87.0\% \text{ and } SM \geq 8.5\% \quad (8)$$

subject to holding speed and discharge area constant.

Results for this example appear in Appendix H. With the same initial test sequence as in Example 7, the minimum corrected airflow of 77.65 lbm/sec was reached in 15 tests at $(\alpha)_1=27.93$ deg, $(\alpha)_2=19.92$ deg, $(\alpha)_3=15.72$ deg, and $(\alpha)_4=9.54$ deg with an efficiency of 87.20% and stall margin of 8.47%.

Example 9:

As a final example, the pressure ratio is maximized at constant speed and discharge area while maintaining minimal acceptable values of efficiency and stall margin (Optimization Goal 17). The problem solution can be stated as

$$\max_{\alpha_1, \alpha_2, \alpha_3, \alpha_4} PR \quad \text{with } \eta \geq 87.0\% \text{ and } SM \geq 8.5\% \quad (9)$$

Results of performing the optimization appear in Appendix I. This example converged in 15 tests at a maximum pressure ratio of 6.105 with an efficiency of 86.82% and stall margin of 10.15%. The optimum vane settings are $(\alpha)_1=21.06$ deg, $(\alpha)_2=10.17$ deg, $(\alpha)_3=5.01$ deg, and $(\alpha)_4=5.01$ deg.

SECTION VI

IDENTIFICATION

Pratt & Whitney Aircraft Group, Government Products Division uses a "Customer Computer Deck" identification system that appears on the outline sheet as

CCD XXXX-XX.X
DATE XX/XX/XX

The first four digits correspond to the compressor vane and bleed optimization program. If another optimization method is developed or studied which does not replace or supercede the original method, a new four-digit number will be used.

Changes in the demonstrator compressor model performance will be related in different dash numbers. The dash number of the original deck will be zero.

The decimal number will be used to reflect all deck changes which do not affect the basic optimization method or compressor model. This includes correcting any program errors.

Any deck change causing a change to the dash number or decimal part of the CCD number will change the previous date of the deck.

**** ** FINAL SOLUTION VALUES ****

VANE ANGLE FOR VANE 1 IS 21.06 DEGREES

VANE ANGLE FOR VANE 2 IS 10.17 DEGREES

VANE ANGLE FOR VANE 3 IS 5.01 DEGREES

VANE ANGLE FOR VANE 4 IS 5.01 DEGREES

PRESSURE RATIO= 6.1050

EFFICIENCY= 86.8000

SURGE MARGIN= 10.1500

REFIC WAS HELD CONSTANT AT 5567.50
OL WAS HELD CONSTANT AT 76.78
