| 20. ABSTRACT (Continue on reverse side if necessary and identify by block number)<br><br>A tactical missile with mid-course requires the use of an Inertial Navigation System (INS). Steady-state Kalman Filters (SKF) used as estimators have been proposed for use in a Strapdown INS that is considered to be cheaper and easier to implement than a gimballed INS. This thesis further investigates the sensitivity of the SKF to inaccuracies in the filter parameters such as the dimensional stability |                                     |                                                                     |

20. ABSTRACT (Continued)

derivatives. The analysis is expanded to explore the sensitivity of a system of higher dimension created by the augmentation of an additional state. The study has been performed by independently varying each of the filter parameters over a given range and noting the effect on the accuracy of the filter. One of the benefits of this analysis of the rms estimate errors to variations in the stability derivatives is that it reveals which derivatives need to be accurately determined to ensure stable flight.

## ABSTRACT

A tactical missile with mid-course requires the use of an Inertial Navigation System (INS). Steady-state Kalman Filters (SKF) used as estimators have been proposed for use in a Strapdown INS that is considered to be cheaper and easier to implement than a gimbaled INS.

This thesis further investigates the sensitivity of the SKF to inaccuracies in the filter parameters such as the dimensional stability derivatives. The analysis is expanded to explore the sensitivity of a system of higher dimension created by the augmentation of an additional state. The study has been performed by independently varying each of the filter parameters over a given range and noting the effect on the accuracy of the filter. One of the benefits of this analysis of the rms estimate errors to variations in the stability derivatives is that it reveals which derivatives need to be accurately determined to ensure stable flight.

### ACKNOWLEDGEMENT

I would like to express my sincere appreciation to Dr. D. J. Collins for his patient guidance and assistance, and steady encouragement during the conduct of this work. Through his leadership our Lord enabled me to complete this thesis and accept an essentially new career as an Engineering Duty Officer.

## I. INTRODUCTION

A tactical missile normally requires midcourse guidance to ensure that its trajectory leads to a specific target. A typical midcourse guidance law pre-programmed strategy maintains constant altitude, heading and speed. Such guidance is primarily effected by an Inertial Navigation System (INS). In this work two steady-state Kalman Filters (SKF), used as estimators of the longitudinal and lateral motion, constitute what may be considered as part of a Strapdown INS onboard a missile that can be cheaper and easier to implement than a gimbaled INS. The authors of [Ref. 1] discuss the basic differences between Strapdown and gimbaled Inertial Navigation Systems.

Sensors on the missile that the longitudinal and lateral estimators could use are described by Maybeck [Ref. 2] and include laser rate gyros, doppler velocimeters, magnetic compasses, and barometric altimeters. A radar seeker could provide a distance or range measurement or range rate. Distance or position measurement could be computed from a signal inserted into the missile's INS from the Global Positioning System (GPS) or similar satellite-based navigation system.

This work was motivated by Bryson [Ref. 3], where he discusses a Strapdown INS using SKF as estimators applied to the model for the DC-8 airplane. To avoid classification requirements and for convenience, the model used here is essentially the same as that of [Ref. 3] rather than that of a missile.

This thesis is a continuation of the work done by Matallana [Ref. 4]. It further investigates the sensitivity of the Kalman Filter to inaccuracies in the filter parameters or variation between the filter model and the plant model for longitudinal motion estimation. The differences could be due to model inaccuracies or to normal variation caused by a changing flight environment. The sensitivity of rms estimate errors to inaccuracies or differences in the stability derivatives is the result of interest.

The initial work conducted was to reproduce the results of [Ref. 3] and [Ref. 4] with the correct implementation of the dynamics in the filter parameters. Then the results of [Ref. 4] for the longitudinal motion estimator with incorrect implementation of the dynamics in the Kalman Filter were reproduced.

After a distance measurement and associated system and measurement noise parameters were added to the model dynamics, the sensitivity analysis was repeated for the longitudinal motion estimator. The analysis of the effect that this distance input had on the sensitivity of the rms errors to inaccuracies or differences in the stability derivatives of the Kalman Filter concluded the research for this thesis.

## II. MODELS AND ESTIMATION

### A. KALMAN FILTER

Only a brief description of the Kalman Filter has been included to show the particular formulation used. A more complete development of general theory is done by Gelb in [Ref. 5].

#### 1. Linear Dynamic System

Consider the linear time invariant system (plant and measurement models) given by equation (1) below, where  $x$  represents the states of the system;  $z$  is the measurement;  $F$  is the system matrix;  $\Gamma$  is the driving noise coefficient matrix;  $H$  is the measurement scaling matrix; and  $w$  and  $v$  are independent, zero-mean, white gaussian noise processes with covariance matrices  $Q$  and  $R$  respectively.

$$\dot{x} = Fx + \Gamma w \quad (1-a)$$

$$z = Hx + v \quad (1-b)$$

Mathematically,  $Q$  and  $R$  are represented by equation (2) as:

$$E(w(t)w^T(\tau)) = Q(t)\delta(t-\tau), E(w(t)) = 0 \quad (2-a)$$

$$E(v(t)v^T(\tau)) = R(t)\delta(t-\tau), E(v(t)) = 0 \quad (2-b)$$

#### 2. Continuous Kalman Filter

A continuous time Kalman Filter is described by equation (3) where  $\hat{x}$  is the state estimate and  $K$  is a matrix of constant filter gains.

$$\dot{\hat{x}} = F\hat{x} + K(z-H\hat{x}) \quad (3)$$

The implementation of the System Model and the Kalman Filter is shown in Figure 1.

Figure 1. System Model and Kalman Filter

The estimate error is defined by equation (4) as

$$\tilde{x} \triangleq \hat{x} - x \quad (4)$$

and the differential equation for  $\tilde{x}$  is given by

$$\dot{\tilde{x}} = (F - KH)\tilde{x} - \Gamma w + Kv \quad (5)$$

The differential equations for the states of a linear system driven by noise can be expressed as

$$\begin{bmatrix} \dot{\tilde{x}} \\ \tilde{x} \end{bmatrix} = \begin{bmatrix} F-KH & 0 \\ 0 & F \end{bmatrix} \begin{bmatrix} \tilde{x} \\ \tilde{x} \end{bmatrix} + \begin{bmatrix} Kv-\Gamma w \\ \Gamma w \end{bmatrix} \quad (6)$$

The covariance of the estimate-error, symbolized as  $P$ , is defined by equation (7). It provides a statistical measure of the uncertainty in  $\tilde{x}$ .

$$P = E(\tilde{x}\tilde{x}^T) \quad (7)$$

The diagonal elements of the covariance matrix are the root mean square errors of the state variables. Also, the trace of  $P$  is the mean square length of the vector  $\tilde{x}$ . The off diagonal terms of  $P$  indicate the degree of cross-correlation between the elements of  $\tilde{x}$ . The covariance matrix  $P$  is obtained by solving the linear Lyapunov equation given by

$$P = (F-KH) P + P(F-KH)^T + \Gamma Q \Gamma^T + K R K^T \quad (8)$$

The eigenvalues of the filter are given by the roots of

$$|sI - F + KH| = 0 \quad (9)$$

## B. STATE AUGMENTATION AND SHAPING FILTERS

When the system random disturbances are correlated in time, i.e., colored noise, it is necessary to use their power spectral density data in order to develop a mathematical model that produces an output which duplicates the noise characteristics [Ref. 2]. Correlated random noises are taken to be state variables of a fictitious linear time invariant system (usually called a shaping filter) which is itself excited by white gaussian noise. Such a model is given by equation (10) below, where the

subscript f denotes filter, and n is a nonwhite (time-correlated) gaussian noise. The filter output is used to drive the system depicted by Figure 2.

$$\dot{\mathbf{x}}_f = \mathbf{F}_f \mathbf{x}_f + \mathbf{\Gamma}_f \mathbf{w} \quad (10-a)$$

$$\mathbf{z}_n = \mathbf{H}_f \mathbf{x}_f \quad (10-b)$$

The dimension of the state vector (1) is increased by including the disturbances as well as a description of the system dynamics behavior in appropriate rows of an enlarged F matrix. This enlargement process is called state vector augmentation.

Figure 2. Shaping Filter Generating Driving Noise

The augmented state equation is given by

$$\begin{bmatrix} \dot{\mathbf{x}} \\ \dot{\mathbf{x}}_f \end{bmatrix} = \begin{bmatrix} \mathbf{F} & \mathbf{\Gamma} \mathbf{H}_f \\ \mathbf{0} & \mathbf{F}_f \end{bmatrix} \begin{bmatrix} \mathbf{x} \\ \mathbf{x}_f \end{bmatrix} + \begin{bmatrix} \mathbf{0} \\ \mathbf{\Gamma}_f \end{bmatrix} \mathbf{w} \quad (11)$$

The associated measurement equation is

$$z = \begin{bmatrix} H & 0 \end{bmatrix} \begin{bmatrix} x \\ x_f \end{bmatrix} + v \quad (12)$$

### C. SENSITIVITY TO PARAMETER VARIATION

Observing the structure of the Kalman Filter illustrated in Figure 1, the filter contains an exact model of the system dynamics.

The analysis of how the error covariance behaves when the gain matrix is computed using perturbed values of the F matrix, such as varying parameters due to different flight conditions, is well explained in [Ref. 5]. Figure 3 is a block diagram of the system model and Kalman Filter with the system dynamics perturbed.  $F^*$  is the perturbed system dynamics, while  $K^*$  is the associated gain matrix computed for the Kalman Filter.

Figure 3. System Model and Kalman Filter with Perturbed Dynamics

The equation for the estimate is given by

$$\hat{\dot{x}} = F^* \hat{x} + K^*(z - H\hat{x}) \quad (13)$$

The error in the estimate is given by

$$\dot{\tilde{x}} = (F^* - K^*H)\tilde{x} + \Delta Fx - \Gamma w + K^*v \quad (14)$$

where

$$\Delta F \triangleq F^* - F \quad (15)$$

The differential equations for the states of linear system driven by white gaussian noise now become

$$\begin{bmatrix} \dot{\tilde{x}} \\ \dot{x} \\ \dot{x} \end{bmatrix} = \begin{bmatrix} F^* - K^*H \\ 0 \end{bmatrix} \begin{bmatrix} \Delta F \\ F \end{bmatrix} \begin{bmatrix} \tilde{x} \\ x \\ x \end{bmatrix} + \begin{bmatrix} K^*v - \Gamma w \\ \Gamma w \end{bmatrix} \quad (16)$$

Letting  $x'$  be the augmented state vector,  $x' \triangleq \begin{bmatrix} \tilde{x} \\ x \\ x \end{bmatrix}$ .

The covariance matrix of  $x'$  is given by

$$E(x'x'^T) = \begin{bmatrix} P & V \\ V^T & U \end{bmatrix} \quad (17)$$

where one defines  $P \triangleq E(\tilde{x}\tilde{x}^T)$ ,  $V \triangleq E(\tilde{x}x^T)$ , and  $U \triangleq E(xx^T)$ .  $P$ , the covariance of  $x$ , is the quantity of interest. The error sensitivity equations are:

$$\dot{P} = (F^* - K^*H)P + P(F^* - K^*H)^T + \Delta FV + V^T\Delta F + \Gamma Q\Gamma^T + K^*RK^{*T} \quad (18-a)$$

$$\dot{V} = FV + V(F^* - K^*H)^T + U\Delta F^T - \Gamma Q\Gamma^T \quad (18-b)$$

and

$$\dot{U} = FU + UF^T + \Gamma Q \Gamma^T \quad (18-c)$$

with initial conditions  $P(0) = -V(0) = U(0) = E(x(0)x(0)^T)$ . When the actual system dynamics are reproduced in the filter,  $F = F^*$  and  $\Delta F = 0$ , and equation (18) reduces to the linear Lyapunov equation of equation (8).

#### D. MODAL COORDINATES TRANSFORMATION

The system represented by equation (1) is not unique. Consider an alternate linear transformation of the states described in references [3] and [6]. Let  $x = T\xi$ , where  $\xi$  represents the transformation of the states and  $T$  is the transformation matrix with the columns formed by the eigenvectors of the system matrix  $F$  (for a complex eigenvalue, the first column is the real part and the second is the imaginary part of the eigenvector). The similarity transformation of equation (1) is

$$\dot{\xi} = A\xi + Bw \quad (19-a)$$

$$z = C\xi + v \quad (19-b)$$

where  $A = T^{-1}FT$ ,  $B = T^{-1}\Gamma$ , and  $C = H T$ .

A case of particular interest, the canonical form, results when the  $A$  matrix is diagonal (i.e., when the eigenvalues of the  $F$  matrix appear on the diagonal). This canonical form is more informative than the transfer function method, since observability and controllability of the system can be obtained by inspection.

#### E. SOLUTION OF THE SKF WITH A PRESCRIBED DEGREE OF STABILITY

The constant gain Kalman Filter (SKF) used as an observer will diverge if undisturbed, neutrally stable (UNS) modes are in the system model. In references [3] and [7] the authors discussed the destabilization of the system model (1). The amount of destabilization can be varied until the suboptimal observer formed has a desired degree of stability. The method of [Ref. 3] destabilizes only the UNS modes in the system model and is called "modal destabilization" (MDS). In this technique the gains of the filter are constrained so that

$$\text{Re}(S_i) > -\sigma, i = 1, 2, \dots, n \quad (20)$$

where  $\text{Re}(S_i)$  indicates the "real" part of  $(S_i)$ ,  $S_1, \dots, S_n$  are the eigenvalues of the filter, i.e., the roots of equation (9), and  $\sigma$  is a specified positive number.

The original system model is destabilized in accordance with equation (21), where  $F'$  is the destabilized matrix formed,  $E$  is the destabilization matrix (diagonal), and  $T$  is the modal transformation matrix (eigenvector matrix). The matrix  $F'$  is used to calculate the suboptimal gains of the filter.

$$F' = F + TET^{-1} \quad (21)$$

This MDS approach prevents the divergence of the steady-state Kalman Filter in a system with UNS model while causing only a slight reduction in the estimation accuracy.

### III. DYNAMIC AND MEASUREMENT SYSTEM MODELS

#### A. REFERENCE AXIS SYSTEM

The Reference Axis System of a missile is centered at its center of gravity (c.g.) and fixed on the missile body as follows:

X axis, the roll axis, forward from the c.g. along the axis of symmetry.

Y axis, the pitch axis, outward to the right from the c.g. when viewing the missile from behind.

Z axis, the yaw axis, downward from the c.g. in the plane of symmetry to form a right-handed orthogonal system with the other two.

Appendix A lists the symbols defining quantities associated with the missile illustrated in Figure 4 below such as forces and moments, linear and angular velocities, and moments of inertia.

Figure 4. Reference Axis System

## B. MISSILE EQUATIONS OF MOTION

The equations of motion used to represent the missile dynamics used in this study are well defined in [Ref. 8]. A linear dynamical model of the missile based on the rigid body approximation is appropriate.

### 1. Longitudinal Motion

The longitudinal motions of a missile can be modeled by a fifth-order system of equation (22), where the state variables are  $u$ , velocity along the X axis,  $w$ , velocity along the Z axis,  $q$ , pitch rate,  $\theta$ , pitch angle and  $h$ , altitude. The units are:  $u$  and  $w$  in 10 ft/s,  $q$  in 0.01 rad/s,  $\theta$  in 0.01 rad, and  $h$  in 100 ft.

$$\begin{bmatrix} \dot{u} \\ \dot{w} \\ \dot{q} \\ \dot{\theta} \\ \dot{h} \end{bmatrix} = \begin{bmatrix} X_u & X_w & 0 & -g & 0 \\ Z_u & Z_w & V & 0 & 0 \\ M_u + M_w Z_u & M_w + M_w Z_w & M_q + M_w V & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & -0.1 & 0 & V & 0 \end{bmatrix} \begin{bmatrix} u \\ w \\ q \\ \theta \\ h \end{bmatrix} \quad (22)$$

### 2. Lateral Motion

The lateral motions of a missile are modeled by the fifth-order system given by equation (23), where the state variables are:  $\beta$ , sideslip angle,  $r$ , yaw rate,  $p$ , roll rate,  $\phi$ , roll angle, and  $\psi$ , heading angle. The units are:  $\beta$  in rad,  $r$  in rad/s,  $p$  in rad/s,  $\theta$  in rad, and  $\psi$  in rad.

$$\begin{bmatrix} \dot{\beta} \\ \dot{r} \\ \dot{p} \\ \dot{\phi} \\ \dot{\psi} \end{bmatrix} = \begin{bmatrix} Y_v & -1 & 0 & g/V & 0 \\ N_{\beta}^1 & N_r^1 & N_p^1 & 0 & 0 \\ L_{\beta}^1 & L_r^1 & L_p^1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \beta \\ r \\ p \\ \phi \\ \psi \end{bmatrix} \quad (23)$$

### C. MODEL DYNAMICS

The aerodynamic data used in this paper appears in Appendix B. Except for the addition of system and measurement noise parameters for the distance input, the models and noise dynamics are the same as those of [Ref. 3].

#### 1. Longitudinal Motion Estimation

The main disturbance inputs are the two wind velocities  $u_g$  and  $w_g$ . Under certain flight conditions, the turbulence represented by the fluctuating parts of  $u_g$  and  $w_g$  are colored noise. They are modeled by first-order shaping filters with white gaussian noise inputs as shown in equation (10). The linear model that results is given by equation (24) [Ref. 4].

$$\begin{bmatrix} \dot{u}_g \\ \dot{w}_g \end{bmatrix} = \begin{bmatrix} -0.413 & 0 \\ 0 & -0.853 \end{bmatrix} \begin{bmatrix} u_g \\ w_g \end{bmatrix} + \begin{bmatrix} 0.413 & 0 \\ 0 & 0.853 \end{bmatrix} \begin{bmatrix} \mu_u \\ \mu_w \end{bmatrix} \quad (24)$$

The numerical data for the longitudinal dimensional derivatives was used in equation (22). The resultant model is represented by equation (25) which corresponds to the state vector augmentation of equation (11). Scaling is done with  $u$ ,  $w$ ,  $u_g$ , and  $w_g$  in units of 10 ft/s,  $q$  in units of 0.01 rad/s,  $\theta$  in units of 0.01 rad, and  $h$  in units of 100 ft.

$$\begin{bmatrix} \dot{u} \\ \dot{w} \\ \dot{q} \\ \dot{\theta} \\ \dot{h} \\ \dot{u}_g \\ \dot{w}_g \end{bmatrix} = \begin{bmatrix} -0.015 & 0.004 & 0 & -0.0322 & 0 & -0.015 & 0.004 \\ -0.074 & -0.806 & 0.824 & 0 & 0 & -0.074 & -0.806 \\ -0.749 & -10.7 & -1.344 & 0 & 0 & -0.749 & -10.7 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & -0.1 & 0 & 0.0824 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -0.413 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -0.853 \end{bmatrix} \begin{bmatrix} u \\ w \\ q \\ \theta \\ h \\ u_g \\ w_g \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0.413 & 0 \\ 0 & 0.853 \end{bmatrix} \begin{bmatrix} \mu_u \\ \mu_w \end{bmatrix} \quad (25)$$

The measurement model shown by equation (26) assumes a rate gyro in order to measure  $z_q$  and a barometric altimeter to measure  $z_h$ .

$$\begin{bmatrix} z_q \\ z_h \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} u \\ w \\ q \\ \theta \\ h \\ u_g \\ w_g \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} v_q \\ v_h \end{bmatrix} \quad (26)$$

## 2. Lateral Motion Estimation

The main disturbance input is the lateral wind  $v$ . The turbulence represented by the fluctuating part of  $v$  is the colored noise, which is also modeled as a first-order shaping filter with white gaussian noise input as given by equation (10). The resulting shaping filter taken from [Ref. 3] is given by equation (27).

$$\dot{\beta}_g = -0.853\beta_g + 0.853\mu \quad (27)$$

where  $\beta_g = v_g/V$ .

The numerical data for the lateral dimensional derivatives was applied in equation (23) to obtain equation (28), which corresponds to the state vector augmentation of equation (11).

$$\begin{bmatrix} \dot{\beta} \\ \dot{r} \\ \dot{p} \\ \dot{\phi} \\ \dot{\psi} \\ \dot{\beta}_g \end{bmatrix} = \begin{bmatrix} -0.0868 & -1 & 0 & 0.03907 & 0 & -0.0868 \\ 2.14 & -0.228 & -0.0204 & 0 & 0 & 2.14 \\ -4.41 & 0.334 & -1.181 & 0 & 0 & -4.41 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -0.853 \end{bmatrix} \begin{bmatrix} \beta \\ r \\ p \\ \phi \\ \psi \\ \beta_g \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0.853 \end{bmatrix} \mu \quad (28)$$

The measurement model given by equation (29) below represents the case where the measurement  $z$  is taken with a roll-rate gyro and the measurement  $z$  obtained from a magnetic compass.

$$\begin{bmatrix} z_p \\ z_\psi \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} \beta \\ r \\ p \\ \phi \\ \psi \\ \beta_g \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} v_p \\ v_\psi \end{bmatrix} \quad (29)$$

## IV. ANALYSIS

### A. SIMULATION

The Sensitivity Covariance Program developed for application in the work of [Ref. 4] was used to solve the error sensitivity equations of equation (18). The program was originally developed to handle a set of 105 linear differential equations for the longitudinal case and 78 for the lateral. The program was revised to accommodate 136 linear differential equations in the longitudinal case and 101 in the lateral, to allow for an additional state augmentation (i.e., the distance measurement to the longitudinal model). The outputs of these programs are the time matrices and rms estimate errors, the square roots of the diagonal elements of the P matrices. The OPTSYS program, the use of which is described by [Ref. 9] and amplified by [Ref. 10], was applied to calculate the Kalman Filter gains to be inserted into the Sensitivity Covariance Program to find the estimate errors for specific system parameter perturbations. The OPTSYS program was also used to destabilize the systems that contained UNS modes in an attempt to eliminate filter divergence. Copies of the OPTSYS and the Sensitivity Covariance programs follow under COMPUTER PROGRAMS, while a copy of [Ref. 10] appears in Appendix C.

### B. RESULTS

As the problem is introduced, the results are presented in three parts: (1) to verify the findings of [Ref. 3] and [Ref. 4] with the correct implementation of the dynamics in the filter parameters, (2) to

reproduce the findings of [Ref. 4] for the longitudinal motion estimator with incorrect implementation of the dynamics in the Kalman Filter, and (3) to conduct a sensitivity analysis of the longitudinal motion estimator after adding a distance measurement and associated system and measurement noise parameters to the model dynamics.

# 1. Motion Estimation Analysis for Exact Dynamics

The OPTSYS program was used with input data representing the actual system dynamics for both the longitudinal and lateral cases to obtain the following results which are the same as those of [Ref. 4] and essentially the same as those of [Ref. 3].

## a. Longitudinal Case

| <u>filter gain matrix K</u> |        | <u>filter eigenvalues</u> |
|-----------------------------|--------|---------------------------|
| 0.059                       | 0.060  | -0.310 + j0.411           |
| 0.264                       | -0.161 | -0.429                    |
| 3.517                       | 0.040  | -0.178                    |
| 0.001                       | -0.080 | -0.261                    |
| -0.011                      | 0.035  | -0.063 + j0.0743          |
| -1.288                      | 0.128  |                           |

## rms estimate errors

|                                  |                                    |
|----------------------------------|------------------------------------|
| $\bar{u} = 2.090 \text{ ft/s}$   | $\bar{\theta} = 0.317 \text{ deg}$ |
| $\bar{w} = 5.102 \text{ ft/s}$   | $\bar{h} = 8.245 \text{ ft}$       |
| $\bar{q} = 0.416 \text{ deg/s}$  | $\bar{u}_g = 4.776 \text{ ft/s}$   |
| $\bar{w}_g = 5.701 \text{ ft/s}$ |                                    |

b. Lateral Case

| <u>filter gain matrix K</u> |        | <u>filter eigenvalues</u> |
|-----------------------------|--------|---------------------------|
| 0.051                       | -0.967 | -2.350 + j2.594           |
| -1.536                      | 0.411  | -0.624 + j0.492           |
| 2.695                       | -0.004 | -0.00125                  |
| 0.386                       | -0.789 | 0.0                       |
| -0.005                      | 0.906  |                           |
| -1.713                      | 0.655  |                           |

rms estimate errors

$$\bar{v}_\beta = 3.329 \text{ ft/s}$$

$$\bar{r} = 0.244 \text{ deg/s}$$

$$\bar{p} = 0.377 \text{ deg/s}$$

$$\bar{\phi} = 0.222 \text{ deg}$$

$$\bar{\psi} = 0.214 \text{ deg}$$

$$\bar{v}_{\beta g} = 5.506 \text{ ft/s}$$

2. Longitudinal Motion Estimation Analysis

The OPTSYS program was used to compute a new  $K^*$  matrix as each parameter of the  $F$  matrix was individually numerically varied. The Sensitivity Covariance Program was then executed utilizing each new  $K^*$  and  $F^*$  matrix pair to determine the rms errors for each individual perturbation.

The results are shown in Tables 1-8 and are identical to those of [Ref. 4]. The true values for the unperturbed system dynamics parameters are indicated in the tables by an asterisk. A discussion of the results follows:

$X_u$ . The dimensional variation of the X force with forward speed  $u$  has a nominal value of -0.015. This quantity was varied in a range of  $\pm 20\%$ . The behavior of the rms estimate errors can be seen in Table 1. The tabulation shows that the numerical variation of the  $X_u$  derivative does not cause significant changes in the nominal values of the rms estimate errors of the states  $\bar{w}$ ,  $\bar{q}$ ,  $\bar{\theta}$ ,  $\bar{u}_g$ , and  $\bar{w}_g$ . The states  $\bar{u}$  and  $\bar{h}$  appear to be slightly effected, but not enough to be of importance.

$X_w$ . The dimensional variation of the X force with downward speed  $w$  has a nominal value of 0.004. Again, a numerical variation in a range of  $\pm 20\%$  was conducted. The behavior of the rms errors is demonstrated by Table 2. Comparing these values with the nominal ones reveals that changes in the  $X_w$  derivative have essentially no effect on the states  $\bar{w}$ ,  $\bar{q}$ ,  $\bar{\theta}$ ,  $\bar{u}_g$ , and  $\bar{w}_g$ , while the states  $\bar{u}$  and  $\bar{h}$  show changes too small to consider important.

$Z_u$ . The dimensional variation of the Z force caused by a change in the forward speed  $u$  has a nominal value of -0.074. The design value was altered in a range of  $\pm 20\%$  with the results shown in Table 3. Evaluation of this data indicates that all the rms errors show some sensitivity except for that of  $\bar{q}$ . The most significant changes occur in the  $\bar{u}$ ,  $\bar{\theta}$ , and  $\bar{h}$  states. The large variation in  $\bar{u}$  can be important in terms of the accuracy in radial position.

$Z_w$ . The dimensional variation of the Z force with downward speed  $w$  has a nominal value of -0.806. The results for this case with changes in  $Z_w$  over a range of  $\pm 20\%$  follow in Table 4. They show that all the rms estimate errors are quite sensitive and any variation of  $Z_w$  beyond  $\pm 2\%$  can be considered critical and unacceptable.

$\underline{M_u}$ . The dimensional variation of the M moment caused by a change in the forward speed  $u$  has a nominal value of -0.000786. From Table 5, one notes that the rms errors for the states  $\bar{q}$ ,  $\bar{u}_g$ , and  $\bar{w}_g$  are not effected by a variation in  $M_u$  of  $\pm 20\%$ , but significant changes are seen when  $M_u$  is varied more than  $\pm 10\%$  in the errors of states  $\bar{u}$ ,  $\bar{w}$ ,  $\bar{\theta}$ , and  $\bar{h}$ .

$\underline{M_w}$ . The dimensional variation of the M moment with speed  $w$  has a nominal value of -0.0111. The results of a numerical variation in a range of  $\pm 10\%$  can be seen in Table 6. Since any alteration in the true value of  $M_w$  has a strong effect on all the rms estimate errors, this derivative can be considered the most critical in the longitudinal motion estimation case.

$\underline{M_q}$ . The dimensional variation of the pitching moment with pitch rate  $q$  has a nominal value of -0.924. The results of Table 7 on the rms estimate errors for a  $\pm 20\%$  change in  $M_q$  show that the sensitivity to variations in this parameter is minimal for all states.

$\underline{M_{\dot{w}}}$ . The dimensional variation of the pitching moment with the rate of change of the downward speed  $w$  has a nominal value of -0.00051. Table 8 contains the rms errors data obtained by altering  $M_{\dot{w}}$   $\pm 20\%$  from its nominal value. All the errors show a degree of sensitivity and the variation of errors is significant when  $M_{\dot{w}}$  is changed by more than  $\pm 2\%$ .

Since plots of the rms estimate errors versus changes in the particular dimensional derivatives for data identical to that of Tables 1-8 appears in [Ref. 4] in Figures 35-40, they will not be repeated in this work. A summary of the relative sensitivity of the rms estimate errors to changes in the individual dimensional derivatives follows in Table 9.

| $M_W$      |    | X  |    |

NS = Not sensitive

RS = Relatively sensitive

VS = Very sensitive

### 3. Analysis of Longitudinal Motion Estimation After Augmentation

Including the distance measurement to the system required state augmentation of the system and measurement models as demonstrated by equations (30) and (31) that follow:

$$\begin{bmatrix} \dot{u} \\ \dot{w} \\ \dot{q} \\ \dot{\theta} \\ \dot{h} \\ \dot{u}_g \\ \dot{w}_g \\ \dot{d} \end{bmatrix} = \begin{bmatrix} -0.015 & 0.004 & 0 & -0.0322 & 0 & -0.015 & 0.004 & 0 \\ -0.074 & -0.806 & 0.824 & 0 & 0 & -0.074 & -0.806 & 0 \\ -0.749 & -10.7 & -1.344 & 0 & 0 & -0.749 & -10.7 & 0 \\ 0 & 0 & 1.0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -0.1 & 0 & 0.824 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -0.413 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -0.853 & 0 \\ 1.0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} u \\ w \\ q \\ \theta \\ h \\ u_g \\ w_g \\ d \end{bmatrix}$$

$$+ \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0.413 & 0 & 0 \\ 0 & 0.853 & 0 \\ 0 & 0 & 1.0 \end{bmatrix} \begin{bmatrix} \mu_u \\ \mu_w \\ \mu_d \end{bmatrix} \quad (30)$$

and

$$\begin{bmatrix} z_q \\ z_h \\ z_d \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} u \\ w \\ q \\ \theta \\ h \\ u_g \\ w_g \\ d \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} v_q \\ v_h \\ v_d \end{bmatrix} \quad (31)$$

In these equations the state variables are u, velocity along the X axis, w, velocity along the Z axis, q, pitch rate,  $\theta$ , pitch angle, h, altitude and d, distance traveled along the X axis. The units are: u and w in 10 ft/s, q in 0.01 rad/s,  $\theta$  in 0.01 rad, h in 100 ft, and d in 10 ft.

The OPTSYS program, when executed with the data from equations (30) and (31) above and the standard deviation values from Appendix B, yielded the following:

filter gain matrix K

$\bar{u}_g$  = 4.776 ft/s

$\bar{w}_g$  = 5.701 ft/s

$\bar{d}$  = 38.730 ft

The next step in the analysis was to perturb each directional derivative independently by specific amounts from its nominal value and to observe the effect on the rms estimate errors. This process was carried out for all eight directional derivatives and the response was the same for each case -- even a slight perturbation of -0.1% of any directional derivative from its nominal value caused the rms estimate errors to increase without bound. This behavior indicated that any incorrect implementation of dynamics in the new system formed by the augmentation of the distance measurement would cause instability and the Kalman filter to diverge.

Several system parameters were individually modified and the analysis repeated in hopes of finding a stable system for which the

Kalman Filter converged. The coefficient for the distance term in the process noise distribution matrix was varied from 0.01-5.0, the power spectral density process noise entry for distance was changed in a range of 1.105-30.0, and the distance term for the power spectral density measurement noise adjusted over a range of 0.03-30.0. None of these trials led to a stable system.

A modal analysis was also performed using the open loop eigenvalues from the OPTSYS output listing. The system of equations (30) and (31) when transformed into modal coordinates give equations (32) and (33) below:

$$\begin{bmatrix} \xi_E \\ \xi_d \\ \xi_{s1} \\ \xi_{s2} \\ \xi_{p1} \\ \xi_{p2} \\ \xi_{u_g} \\ \xi_{w_g} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -1.076 & 2.957 & 0 & 0 & 0 & 0 \\ 0 & 0 & 2.957 & -1.076 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -0.006 & 0.024 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0.024 & -0.006 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -0.413 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -0.853 \end{bmatrix} \begin{bmatrix} \xi_E \\ \xi_d \\ \xi_{s1} \\ \xi_{s2} \\ \xi_{p1} \\ \xi_{p2} \\ \xi_{u_g} \\ \xi_{w_g} \end{bmatrix} + \begin{bmatrix} 0 & 0.1 & 0 \\ -1.0 & 0 & 1.0 \\ -0.028 & -0.088 & 0 \\ -0.110 & -3.153 & 0 \\ 1.027 & -0.048 & 0 \\ -0.210 & 1.467 & 0 \\ 0.420 & 0 & 0 \\ 0 & 1.836 & 0 \end{bmatrix} \begin{bmatrix} \mu_u \\ \mu_w \\ \mu_d \end{bmatrix} \quad (32)$$

$$\begin{bmatrix} z_q \\ z_h \\ z_d \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1.0 & 0 & -0.0001 & 0.0005 & 0.0548 & 0.4802 \\ 1.0 & 0 & 0.0016 & 0.0016 & -0.0156 & -0.0612 & 0.0082 & -0.0025 \\ 0 & 1.0 & -0.0008 & -0.0004 & 1.0 & 0 & -0.0657 & -0.0252 \end{bmatrix} + \begin{bmatrix} \xi_E \\ \xi_d \\ \xi_{s1} \\ \xi_{s2} \\ \xi_{p1} \\ \xi_{p2} \\ \xi_{u_g} \\ \xi_{w_g} \end{bmatrix} \\
 + \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} v_g \\ v_h \\ v_d \end{bmatrix} \quad (33)$$

Consistent with the discussion in [Ref. 3], inspection of equation (32) revealed that the energy mode  $\xi_E$  and the distance mode  $\xi_d$ , were neutrally stable (i.e., eigenvalues = 0). Inspection of equation (33) showed that  $\xi_E$  was unobservable with  $z_q$  and  $z_d$  and that  $\xi_d$  was unobservable with  $z_q$  and  $z_h$ . Equation (32) also disclosed that  $\xi_E$  was undisturbed by  $u_g$  and  $d$ , and that  $\xi_d$  was undisturbed by  $w_g$ . Therefore, destabilization was conducted in an attempt to prevent filter divergence. Both total and modal destabilization described earlier in this work and in [Ref. 3] were performed in amounts of 0.040 and 1.0 using the OPTSYS program. The filter gains computed for the destabilized system were then executed in the Sensitivity Covariance Program with each of the modified parameter combinations discussed earlier. Without exception, the rms estimation errors increased without bound when the least sensitive dimensional derivative  $X_u$  was perturbed by as little as  $\pm 1\%$ .

## V. CONCLUSIONS AND RECOMMENDATIONS

### A. CONCLUSIONS

The conclusions reached were based on the results obtained and will therefore be presented in three parts.

#### 1. Motion Estimation Analysis for Exact Dynamics

The data in the results is in agreement with that of both [Ref. 3] and [Ref. 4]. It shows that both the Kalman Filters for initial longitudinal and lateral cases are stable when the true values for the system dynamics are implemented.

#### 2. Longitudinal Motion Estimation Analysis

The results from Tables 1-8 and summarized in Table 9 are consistent with those of [Ref. 4]. The stability derivatives  $Z_w$  and  $M_w$  cause the strongest changes in the rms estimate errors when they are varied. Basically,  $Z_w$  and  $M_w$  must be quite accurately reproduced in the filter to prevent divergence. Changes in the stability derivatives  $Z_u$ ,  $M_u$ , and  $M_{\dot{u}}$  reflect intermediate variations in nearly all the rms estimate errors. For the model considered a tolerance of more than  $\pm 5\%$  affects the accuracy in the radial position since large variations in  $\bar{u}$  occur. A tolerance of perhaps  $\pm 20\%$  can be accepted in the dimensional derivatives  $X_u$ ,  $X_w$ , and  $M_q$  for this model since no important effect is noted in the rms errors over that range.

#### 3. Analysis of Longitudinal Motion Estimation After Augmentation

From the results presented earlier for the new system model formed by the augmentation of a distance measurement and associated process and

measurement noise parameters, it is apparent that the corresponding Kalman Filter will diverge for even a slight variation in any of the dimensional derivatives from their nominal values. Even the Kalman Filter developed by system destabilization proved to be unstable with the parameters used.

#### B. RECOMMENDATIONS

Further analysis of the augmented system including the distance or position estimation is desirable. Perhaps a more in-depth study of the measurement parameter scaling would enable the development of a stable Kalman Filter for at least a destabilized system.

## VI. SUMMARY

The sensitivity analyses performed in this work have revealed the importance of accuracy in determining system dynamics utilized in formulating the model for the Kalman Filter. The relative sensitivity of the rms estimation errors to variance in each of the particular dimensional derivatives is shown in Table 9 for the Longitudinal Motion Estimator.

The longitudinal system augmented with the distance measurement developed appears to be extremely sensitive to variations in all the dimensional derivatives. Further analysis of the model developed is suggested.

$$\sigma_\psi = 1.5 \times 10^{-5} \text{ 1/s}$$

APPENDIX C  
AN AID TO USING OPTSYS AT NPS

I. INTRODUCTION

One of the tasks involved in my thesis work at the Naval Postgraduate School (NPS) was to verify some of the data of reference [1] which investigated the sensitivity of the Steady-State Kalman Filters as lateral and longitudinal estimators in Strapdown Inertial Navigation Systems (INS). One of the recurring, essential calculations was for the steady-state gains of each system model considered. Fortunately, the OPTSYS computer program was available in Fortran at the computer center to help perform this enormous job. The use of the OPTSYS program was covered by reference [2], but not in adequate detail for easy application. After much trial-and-error, frustration, attempted decoding with the assistance of the computer center staff, and prayer, and at the expense of many man-hours of time, our Lord enabled me to properly fill out and order the data cards for a particular modeled system and obtain the expected results upon execution of the program. Since Professor Collins has several other students in need of a users working knowledge of the OPTSYS program and anyone using Kalman Filters can benefit as well, I am writing a more detailed description of how to correctly input data by discussing a specific example. The intent of this paper is to supplement the guidance of reference [2] and further facilitate research at NPS.

## II. MODEL AND ESTIMATION

Consider the linear time-invariant system given by

$$\dot{x} = Fx + \Gamma w$$

$$z = Hx + v$$

where  $x$  represents the states of the system;  $z$  is the measurement vector;  $F$  is the system matrix;  $\Gamma$  is the driving noise coefficient matrix;  $H$  is the measurement scaling matrix; and  $w$  and  $v$  are independent, zero-mean, white gaussian noise processes with covariance matrices  $Q$  and  $R$ , respectively.

A continuous time Kalman Filter for this system is described by

$$\dot{\hat{x}} = F\hat{x} + K(z - H\hat{x})$$

where  $\hat{x}$  is the state estimate and  $K$  is the matrix of the steady-state gains of the Kalman Filter. The implementation of the System Model and the Kalman Filter are shown below in Figure C-1 [Ref. 1].

Figure C-1. System Model and Kalman Filter

### III. AN EXAMPLE OF LONGITUDINAL MOTION ESTIMATION

After state vector augmentation, the resultant model of longitudinal motion of an aircraft of the form  $\dot{\mathbf{x}} = \mathbf{F}\mathbf{x} + \mathbf{G}\mathbf{w}$  is

$$\begin{bmatrix} \dot{u} \\ \dot{w} \\ \dot{q} \\ \dot{\theta} \\ \dot{h} \\ \dot{u}_g \\ \dot{w}_g \end{bmatrix} = \begin{bmatrix} -0.015 & 0.004 & 0 & -0.0322 & 0 & -0.015 & 0.004 \\ -0.074 & -0.806 & 0.824 & 0 & 0 & -0.074 & -0.806 \\ -0.749 & -10.7 & -1.344 & 0 & 0 & -0.749 & -10.7 \\ 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & -0.1 & 0 & 0.0824 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -0.413 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -0.853 \end{bmatrix} \begin{bmatrix} u \\ w \\ q \\ \theta \\ h \\ u_g \\ w_g \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0.413 & 0 \\ 0 & 0.853 \end{bmatrix} \begin{bmatrix} \mu_u \\ \mu_w \end{bmatrix}$$

where the units are scaled such that  $u$ ,  $w$ ,  $u_g$ , and  $w_g$  must be multiplied by 10 to give feet per second,  $q$  by 0.01 to give radians per second,  $\theta$  by 0.01 to give radians, and  $h$  by 100 to give units of feet [Ref. 1].

The corresponding measurement model in the form  $z = Hx + Iv$  is given by

$$\begin{bmatrix} z_q \\ z_h \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} u \\ w \\ q \\ \theta \\ h \\ u_g \\ w_g \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} v_q \\ v_h \end{bmatrix} \quad (26)$$

For this model  $Q_u = Q_w = 1.105 \text{ (10 ft/s)}^2/\text{s}$ ,  $R_q = 0.15 \text{ (0.01 rad/s)}^2$  and  $R_h = 0.05 \text{ (100 ft)}^2 \text{ s}$  [Ref. 3].

#### IV. APPLYING OPTSYS TO THE EXAMPLE

The essential input data that will enable OPTSYS to calculate the steady-state gains of the Kalman Filter and many other parameters outlined in [Ref. 2] follows on page 55. The input data and control cards are described in the paragraphs below.

Card 1 - The 17 entries in every other column from column 2 through column 34 essentially tell OPTSYS what to compute. See [Ref. 2] for more details.

Card 2 - The 5 entries in every third column from 3 through 15 describe the system being modeled to OPTSYS. The first entry tells the number of states or order of the system-7 since there are seven rows in the  $F$  matrix. The second entry gives the number of controls-0 since  $u=0$ . The third entry tells that we have 2 measurements, while the fourth entry shows that two process noise sources exist. The fifth entry is always zero when filter synthesis is done. See [Ref. 2] if regulator synthesis only is desired.

Cards 3-16 - These cards contain the  $F$  matrix. The first six entries of each row go on one card with 12 columns for each entry-1-12, 13-24, ..., 60-72. The seventh entry for each row is placed in columns 1-12 of a continuation card that immediately follows the card with the first six entries of the row. Note that if our example system were 6x6, the  $F$  matrix would only take up cards 3-8.

The next three cards, 17-19 in our example, contain the H matrix. Note that this matrix is also entered on the cards by rows, but consecutively with an entry in every 12 columns with 6 entries per card as long as unused row elements remain! Thus the first entry of row 2 of the H matrix appears in columns 13-24 of card 18.

The next three cards, 20-22, hold the  $\Gamma$  matrix. This matrix is also entered consecutively by rows with an entry in the first 14 groups of 12 columns on the cards!

The next to the last card gives the Q matrix. Note that this card has only the diagonal terms of the matrix in columns 1-12 and 13-24. See [Ref. 2] for matrices with non-diagonal terms.

The last card is for the R matrix and also has diagonal entries in columns 1-12 and 13-24. Again refer to [Ref. 2] if non-diagonal terms exist.

This supplement will be effective until the OPTSYS program is re-coded in WATFIV language. Its usage should greatly improve the efficiency and morale of those using the OPTSYS program on file at NPS Computer Center.

SENSITIVITY COVARIANCE PROGRAM

THIS PROGRAM IS USED TO SOLVE THE SET OF SENSITIVITY
EQUATIONS WHEN THERE IS AN INCOMPLETE REPRESENTATION
OF DYNAMICS IN THE DESIGN OF THE KALMAN FILTER. THE
EQUATIONS BECOME

$$PDOT = (F^* - K * H) * P * (F^* - K * H)^T + D * PDPT + G * GGT + K * K * K^T$$

$$VDOT = FV + V / (F^* - K * H)^T * UDPT - G * GT$$

$$UDOT = FV * UFT + G * GT$$

THE PRINCIPAL PROGRAM INPUTS ARE THE FOLLOWING CO-
LECTION OF SYSTEM AND FILTER MATRICES

PO THE INITIAL COVARIANCE MATRIX (NXN)
F THE TRUTH MODEL DYNAMICS MATRIX (NXN)
F* THE FILTER MODEL DYNAMICS MATRIX (NXN)
H THE TRUTH MODEL MEASUREMENT MATRIX (LXN), WHERE

CCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCCC
                                SENSITIVITY COVARIANCE PROGRAM
THIS PROGRAM IS USED TO SOLVE THE ERROR SENSITIVITY
EQUATIONS WHEN THERE IS AN INCORRECT IMPLEMENTATION
OF DYNAMICS IN THE DESIGN OF THE KALMAN FILTER. THE
EQUATIONS BECOME
PDDT = (F* - K*H) P* P (F* - K*H) T + DFV + VTDFT + GQGT + K* RK* T
VDDT = FV + V (F* - K*H) T + UDTT - GQGT
UDDT = FU + UFT + GQGT
THE PRINCIPAL PROGRAM INPUTS ARE THE FOLLOWING CO-
LECTION OF SYSTEM AND FILTER MATRICES
PD    THE INITIAL COVARIANCE MATRIX (NXN)
F*    THE TRUTH MODEL DYNAMICS MATRIX (NXN)
F     THE FILTER MODEL DYNAMICS MATRIX (NXN)
H     THE TRUTH MODEL MEASUREMENT MATRIX (LYN), WHERE
      L IS THE MEASUREMENT VECTOR DIMENSION
GQGT  THE INPUT NOISE COVARIANCE MATRIX (NX)
R     THE MEASUREMENT NOISE COVARIANCE MATRIX (LYL)
K*    FILTER GAIN (NXL)
