20. ABSTRACT (Continue on reverse side if necessary and identify by block number) Forecast aids are provided for predicting wind conditions at a station when a tropical cyclone passes within 360 n mi. The forecast aids were produced by analyzing a data set comprising the ratios of station wind values to tropical cyclone center wind values. Ratio values were then assigned to the position of the cyclone center. The 360 n mi radius circle about the station was divided into 71 equal area segments and the values of the mean and maximum ratio within each segment were subjectively analyzed to produce the forecast aids.

1. INTRODUCTION

Forecasting wind conditions at a station during the passage of a tropical cyclone is a critical problem for operational environmentalists. The Air Force has produced forecast aids for predicting mean and maximum peak gusts, for several western Pacific Air Force Bases (Pettett, 1980), for periods when a typhoon was within 360 n mi of a base. The need for similar forecast aids for Navy sites was recognized and the Naval Environmental Prediction Research Facility (NEPRF), Monterey, California was requested to produce the aids. Science Applications, Inc., under contract to NEPRF has conducted the research and development involved in producing forecast aid reports for Yokosuka, Japan and Cubi Point, Philippines.

2. PRODUCTION OF FORECAST AIDS

The forecast aids are based on a data period extending from the establishment of a U.S. Navy weather observation program at the stations of interest through 1979. This is a 27 year period for Yokosuka (1953-1979) and 25 years for Cubi Point (1955-1979). Best track data for the tropical cyclones were extracted from Joint Typhoon Warning Center (JTWC) records for the periods when a tropical cyclone was within 360 n mi of the station of interest. Aviation hourly observations at three-hour intervals, obtained from the National Climatic Center (NCC), Asheville, NC, were extracted for the periods identified as having a tropical cyclone within 360 n mi of the station.¹ The best track

¹Aviation hourly observations are archived at NCC for the local times corresponding to 00,03,06,09,12,15,18,21 GMT only.

and weather observations were then merged into a new data base. From this data, ratios of storm center winds to station reported sustained winds were determined and assigned to the storm center position. The 360 n mi radius circle was divided into 71 equal areas (Fig.1).

The ratios identified with each area were summarized and maximum and mean gust ratios and standard deviations were determined. The number of ratios per area (sample size) and cumulative frequency distribution of the ratios were also computed. Computer plots of the gust ratios, sample size and area number values were generated. The gust ratio plots were then subjectively analyzed taking into consideration such factors as sample size for the mean gusts and cumulative distribution frequency for the maximum gusts.

The analyses of the data are presented as isolines which represent the climatological mean or maximum gust to be expected at the station as a percentage of the tropical cyclone center wind. The data base is separated into two classifications of cyclones, i.e., typhoons and lesser tropical cyclones. The classification is based on the cyclone center wind speed at the time of the station wind observation. A set of analyses is provided for each cyclone classification. In addition, a table containing all the data necessary to produce figures 1 through 5 is provided. The data in the table will assist local reanalysis if required.

Figure 1. A 360 n mi radius circle divided into 71 equal area (5734.5 n mi^2) segments which can be centered on the station of interest. The circle is comprised of an inner circle and five surrounding rings. The radial thickness of each ring is approximately 60 n mi, but is not a constant. The segments are numbered from the inner circle and spiral outward.

3. USE OF THE FORECAST AIDS

The forecast aids can be utilized as follows:

- 1) Locate the actual or forecast tropical cyclone center position on the appropriate forecast aid analysis; 2) determine the maximum gust ratio value by interpolating between the contours; and 3) apply this ratio (percentage to the cyclone center wind value to obtain the maximum or mean gust values to be used as a forecast aid in making the wind forecast. For example, if a tropical cyclone has center winds of 100 kt and a ratio of .65 was determined above, then 65% of the center wind gives forecast gusts to 65 kt for the station.

Sustained one-minute maximum and average wind values can be found by applying a factor of $2/3$ to the gust values. This factor is the inverse of the 1.5 to 1 ratio of gusts to sustained winds that was used in the Air Force reports and verified as follows. A study of the wind observations recorded at Cubi Point (1953-1979) and Yokosuka (1955-1979) was made as part of the development of the methodology used in producing these forecast aids. That data set included the NCC tape archived data, hand augmented with gust data. A uniform ratio of gust to sustained wind speed of 1.5:1 was found over various speed ranges and at both stations. The data set included all station observations (Cubi Point 3449 and Yokosuka 2114) with sustained winds of 10 knots or more when a tropical cyclone was within 360 n mi of the station. This ratio was found to be reasonable for all tropical cyclone intensity classifications and station wind conditions.

Forecasters should recognize that all of the gust information is based on the archived sustained winds (aviation observations at three hour intervals from NCC) multiplied by 1.5. In determining this multiplier, local effects as they relate to various wind directions were only indirectly taken into account. That is, the ratios assigned to each area relate only to storms centered in that area. The storm center location relative to the station location strongly influences the station wind velocity. Therefore, some degree of local effects are inherent in the analyzed ratio patterns.

Table 1 summarizes the data used in producing the forecast aids. The data in Table 1 is sufficient to reproduce figures 1 through 5 should local reproduction or modifications be desired. The ratio values in Table 1 represent the relationship of station sustained winds to tropical cyclone center winds. To derive the forecast aids for gust values the 1.5 multiplier must be applied.

Figures 2 through 5 are the forecast aid analyses. The contours are labelled as percentages which were derived from the ratios of station winds to tropical cyclone center winds. Note that the center contours on all but figure 2 are less than 100 percent. For example, the maximum gust aid for typhoon strength tropical cyclones (Fig.4) shows only a 70 percent contour around the station. Table 1, segment 1 for tropical cyclones of 64 kt or greater shows 16 cases of typhoon strength centers being located within the area of segment 1. The maximum sustained wind to typhoon center wind ratio that occurred during the 16 cases is .494 to 1. Segment 3, located east of the station (Fig.1), shows

14 cases of typhoon strength centers with a maximum ratio of .521 to 1. Applying the 1.5 multiplier to the ratios of segments 1 and 3 results in the data that supports the 70 percent contour.

The interpretation of figure 4 is that Cubi Point has not experienced winds at the official observation point of as great an intensity as the official typhoon center winds during typhoon passages. While these findings are based on a reasonable sample size, caution should be used in applying these results when a typhoon center is expected to pass over or very near the station.

Inconsistent gust values will be obtained from the aids when a tropical cyclone center wind change results in a change of cyclone classification and therefore a change of forecast aid. For example, use of figure 2 for a tropical storm forecast to pass over the station with 60 kt center winds would indicate a maximum gust of 72 kt. A change in center wind to 65 kt and the use of figure 4 indicates 46 kt maximum gusts. An intermediate value is the likely best guidance in such cases.

REFERENCE

Pettett, J.E., 1980: Prediction of Typhoon-Induced Peak Winds at Four Pacific Stations. 1WW/TN-80/001.

Figure 2. Maximum Gust Ratios (labelled as percentage) for Cubi Point when a tropical cyclone of less than typhoon strength (<64 kt) is centered within 360 n mi of the station. Locate the typhoon center by latitude and longitude and interpolate the ratio (percentage) value. Multiply the typhoon center wind speed by this percentage to get the wind speed value of the maximum gust expected with the given center position and wind speed. Multiply the maximum gust speed by 0.67 to find the maximum one-minute average sustained wind speed.

Figure 3. Mean Gust Ratios (labelled as percentage) for Cubi Point when a tropical cyclone of less than typhoon strength (<64 kt) is centered within 360 n mi of the station. Locate the typhoon center by latitude and longitude and interpolate the ratio (percentage) value. Multiply the typhoon center wind speed by this percentage to get the wind speed value of the mean gust expected with the given center position and wind speed. Multiply the mean gust speed by 0.67 to find the mean one-minute average sustained wind speed.

Figure 4. Maximum Gust Ratios (labelled as percentage) for Cubi Point when a tropical cyclone of typhoon strength (≥ 64 kt) is centered within 360 n mi of the station. Locate the typhoon center by latitude and longitude and interpolate the ratio (percentage) value. Multiply the typhoon center wind speed by this percentage to get the wind speed value of the maximum gust expected with the given center position and wind speed. Multiply the maximum gust speed by 0.67 to find the maximum one-minute average sustained wind speed.

Figure 5. Mean Gust Ratios (labelled as percentage) for Cubi Point when a tropical cyclone of typhoon strength (≥ 64 kt) is centered within 360 n mi of the station. Locate the typhoon center by latitude and longitude and interpolate the ratio (percentage) value. Multiply the typhoon center wind speed by this percentage to get the wind speed value of the mean gust expected with the given center position and wind speed. Multiply the mean gust speed by 0.67 to find the mean one-minute average sustained wind speed.

Table 1. A listing of the data used in producing figures 1 through 5, and other general information. Table contents by column are: segment number, latitude and longitude of segment center, maximum ratio, mean ratio, standard deviation of ratios, number of ratios (sample size), and cumulative frequency distribution expressed as the percentage of ratios occurring between 0.0 and the maximum ratio or 1.0 in 0.1 increments.
