1. SUMMARY

An effort to apply fiberglass reinforced plastic (E-glass-epoxy) to the construction of an M939/M963 hood/fender assembly was undertaken. Material characterization and the finite element analysis were completed.

Soft tooling for both hoods was made and pre-production prototypes of the M939 hood/fender assembly were made. The feasibility of manufacture was proved.

2. PREFACE

A contract was awarded to Ewald Associates, Inc., Detroit, MI, to design the hood/fender assembly from fiberglass-reinforced plastic. The original hood/fender assembly selected was that of the XM963 2-1/2-ton truck. Midway through the project, the hood/fender assembly to be used was changed to the M939 5-ton truck. In February 1980, orders were received to terminate the project; thus, the contract was terminated for the convenience of the Government. On both vehicles, soft tooling was completed and drawings were made. Material characterization and finite element were completed. This report discusses the finite element analysis of the structures and the material characterization studies and also the tooling development. It should be pointed out that two complete hood/fender assemblies of the M939 5-ton truck configuration were molded of fiberglass-bonded with a resin which would not perform at the high temperature specified for vehicle operation.

3. INTRODUCTION

The automotive industry, pushed by the requirement for improved fuel economy, is exploring any avenue which can reduce their product's appetite for fuel. Their search has led them to evaluate many materials which can reduce weight. One of the materials proven to be satisfactory is reinforced fiberglass in an epoxy resin. Current forms of fiberglass/epoxy plastic have been developed which can be molded or formed like sheet steel. Ideally, weight reductions of up to 60% can be achieved, if the substitution is on a density basis; however, 57 actual parts are designed to mechanical properties and, consequently, result in 30-40% weight reductions. To apply these materials to the Army's 2-1/2-ton and 5-ton product improved trucks requires the development of technology to produce these items.

4. OBJECTIVE

The program objective was to determine the production parameters required to manufacture the reinforced fiberglass hood/fender assembly for the M939 5-ton series trucks, and whether or not the reinforced assembly could perform in the military environment of extreme heat and cold and high humidity.

The current need to achieve high fuel economy requires that methods of reducing weight be investigated. As a start in vehicle weight reduction, it was decided to evaluate the change of material of certain components from steel to tailored reinforced fiberglass plastic. The original steel (low carbon, hot rolled, pickled and oiled with a minimum of temper 3) has a minimum yield strength of 36,000 PSI. The steel structure is a multipiece assembly welded and bolted together. The one-piece, reinforced-plastic hood/fender design is to have the same strength level as steel. This performance is to be expected with underhood temperatures ranging up to 250°F. Simplicity of design is to be achieved by the reduction of the number of pieces in the current steel hood/fender assembly.

5. CONCLUSIONS

1. Materials and configuration selected in conjunction with the finite element analysis are adequate.
2. The program, as conducted, did not provide the technology to go into full-scale production.
3. Vehicular testing was not conducted; therefore, no conclusions could be drawn as to whether or not the hood/fender assembly could perform in the military environment.

6. DISCUSSION

The material characterization data and the finite element analysis data were incorporated into the design shown on the drawings. The tooling was manufactured, but no parts were made, because the contract was terminated.

Ply lay-up sequence for the manufacture of the various components of the hood/fender assembly, using E-glass with an epoxy resin-NARMCO 5213 epoxy was as shown in Tables 1 and 2. The cure procedure was as follows:

- a. Vacuum bag each mold to remove volatiles.
- b. Pressurize to 28 in. of mercury.
- c. Heat to 300°F for six hours and cool slowly to room temperature.
- d. Remove pressure.
- e. Remove panel and inspect.

The entire design was based on a flexural strength of 39,000 PSI at 200°F. This strength level allows the hood/fender assembly to function over the required lower temperature range of -50°F; the NARMCO 5213 resin system softening at temperature of 250°F and below.

A hood/fender assembly of these materials weighs 162 pounds $\pm$ 5%. The weight removed is 162 pounds $\pm$ 5% which amounts to a weight savings of 47%.

7. FINITE ELEMENT ANALYSIS

In order to assure that the proposed design will be at minimum weight and still provide the necessary strength level, a finite element analysis was made; a computer model was established. This model for the various hood/fender assembly elements is shown in figures 1 - 6. The computer program selected was NISA. Each element is numerically defined with the corresponding node coordinates, shown in figures 1 - 6. The stress levels obtained in these cases were based on the modulus of elasticity of the material being considered.

The finite element analysis was conducted, using three different sets of input parameters. These are as follows:

a. The first is identified as load case A-1. The input parameters are:

(1) Material thickness is 0.125 inches.

(2) The load is 1,000 pounds uniformly distributed over the upper, outer hood panel surface.

This load is to simulate the transportation of five human beings (200 pounds each) lying flat on the surface of the hood. Loads resulting from the opening and closing of the hood/fender assembly are insignificant for consideration in the overall structural analysis. Their effect is localized at the handle and latch attachment points. These require reinforcement in the areas of high stress concentration.

b. The second is identified as load case B-1. The input parameters are:

(1) Material thickness is 0.100 inch.

(2) The load is 1,000 pounds, uniformly distributed over the upper, outer hood panel surface.

c. The third is identified as load case B-2. The input parameters are:

(1) Material thickness is 0.100 inch.

(2) The load is 500 pounds, simulating two men of 250 pounds each standing on the fender. Man no. 1 is standing on an area of 103 sq-in., located to the rear of the center of the fender, and man no. 2 is standing on an area of 97 sq-in. located forward of the center of the fender. Man no. 1 exerts a downward force of 2.43 lb/sq-in. and man no. 2 exerts a downward force 2.56 lb/sq-in. Only one-half of the hood was analyzed, due to the symmetry about the longitudinal center line of the vehicle.

In figure 7 - 37 load case A-1, all of the various computer-generated stresses are shown. Transverse stresses (S_{xx}), longitudinal stresses (S_{yy}), shear stresses (S_{xy}), maximum principal stresses (S_3 figure 35) and the Von mises stresses (S_{eq}), figure 36, were calculated for all hood assembly panels. Figure 37 depicts the deformation of the hood. Because shell analysis was used for this, both top and bottom surfaces of each panel were evaluated and the results are shown. The stress contours shown in each figure represent lines of equal stress.

Figure 38 depicts the hood deformation arising from the parameters of load case B-1. Figures 39 - 68 show the stress levels generated by the analysis for this load case B-1.

Figure 69 depicts the hood deformation arising from the parameters of load case B-2. It should be noted that most of the deformation is on the fender, because the load application is directly to the fender.

Figure 70 - 79 show the stress levels generated by the analysis for this load case B-2.

None of the stresses generated by the computer are excessive for this load case B-2.

Based on the input loads and the strength of the reinforced plastic combination selected, the hood/fender assembly material was selected based on a flexural strength at 250°F and 39,000 PSI and a flexural modulus of 2.2×10^6 PSI. The actual material ply lay-up sequences were based on the material characterization study.

8. MATERIAL CHARACTERIZATION STUDY

8.1. Test Material

To achieve maximum strength at minimum weight, a material characterization study was conducted. The basic material was an E-glass fabric/epoxy prepreg composed of eight plies, compression molded together, using NARMCO 5213 epoxy. Three different fabric orientations were evaluated with a final thickness of 0.080 after the cure cycle. In each case, the cure cycle was as follows:

- a. The air in the mold was evacuated.
- b. The dies were heated to 300°F.
- c. The plaque was placed under pressure and held at 300°F for 45 minutes.
- d. The mold was air cooled to room temperature.
- e. At room temperature, the plaque was removed and inspected.

The following material combinations were manufactured into test plaques and subjected to mechanical property tests:

- a. Combination identified as no. 1 and J were laid up, using the following fiberglass orientation sequence: 8 plies (0°, 90°, 0°, 90°) 2s.
- b. Combinations identified as no. 2 and C were laid up using the following fiberglass orientation sequences: 8 plies (+45°, -45°, +45°) 2s.
- c. A combination identified as no. 4 was laid up using the following fiberglass orientation sequence: 10 pliers (0°, 90°, +45°, -45°).
- d. A combination identified as K was laid up as follows: (0°, 90°, +45°) 2s.

8.2 Test Equipment and Procedures

Test equipment utilized in conducting the test to ASTM-D-790 was an Instron Model 1123. The samples were conditioned for a minimum of 24 hours at 72°F with relative humidity at 50% for room temperature evaluation; samples were also conditioned at -40°F and 200°F. The cross head which applied the load was moved at a speed of 0.05 inch a minute. The following data were obtained from plaques 1, 2 and 4: flexural strength and flexural modulus. See Tables 3,4,5,6 and Chart no. I. The following data were obtained from plaques C, J and K: Yield strength, ultimate tensile strength, tensile modulus, elongation. Results are shown in Table 6. Based on the data obtained in the flexural testing to ASTM-D-790, the flexural strength and flexural modulus are greater at sub-zero temperatures than at elevated temperatures (250°F for this application). The data obtained rank the materials as follows:

- a. 0, 90° orientation
- b. 0, 90°, 45° orientation, maybe 90°, 90° $\pm$ 45°
- c. $\pm$ 45° orientation

The results also indicate that materials with (0°, 90°) and (-0°, 90°, $\pm$ 45°) will provide the minimum required strength at elevated temperatures. The room temperature properties are more than adequate for most operating environments. Because the contract was terminated, neither impact nor fatigue data were obtained.

CHART I.

FIBERGLASS/EPOXY PLASTIC WITH VARIOUS PLY ORIENTATIONS

9. PROTOTYPE TOOLING DEVELOPMENT

The tooling for the manufacture of both 2-1/2-ton and 5-ton truck hoods was based on the use of an actual steel hood/fender assembly furnished by the US Army Tank-Automotive Command. They were disassembled to be used as master tooling aids. The following components were used in the mold development:

a. Hood Outer Panel--the total outer panel including the right, left and center pieces were used as a single unit upon which to generate the plaster tooling necessary to manufacture the plastic component.

b. Right hand side fender panel.

c. Right hand side vertical panel.

d. Left hand side fender panel.

e. Left hand side vertical panel.

The surface of each panel is a mirror image of the required engineering section. Using these, individual molds were made using the described procedure.

Each panel was internally crated using wood reinforcement to provide a solid structure. Each reinforced panel was enclosed with high grade wood to provide a completely integrated box. Vertical and horizontal surfaces were constructed to provide additional support to the plastic tooling during the lamination procedures. Each box was airtight, so that leakage did not occur during the mold fabrication.

Molds were laminated to duplicate the exact outer surface of the steel panels. Layers of hand-laid glass cloth were impregnated with high temperature epoxy.

This was followed by the addition of 12 layers of additional reinforcement for the mold. These reinforcements were applied in two steps.

Six layers were hand-laid, impregnated with epoxy and vacuum bagged for 24 hours. At least 24 layers of fiberglass impregnated with high temperature epoxy resins were used to create the plastic tools.

Vacuum bagging was used to conform those layers to the outer surface of the steel panels. A vacuum of at least 23 in. Hg was applied for a period of at least 24 hours. Vacuum was applied after the lamination of every six fiberglass layers. After this period, the molds were hard enough to prevent spring-back from the master tool surface and the bottom surface of the mold. This resulted in a completely integrated mold with vertical reinforcements.

The overall assembly was then cured at 300°F for three hours. The woodframe was removed from each mold at the end of the cooling cycle. The molds were inspected for any delamination or imperfections. The bottom surface of each mold was then machined flat to provide an even surface for future part lay-up. A flat plastic panel was cut and attached to the bottom surface of the mold. This approach resulted in high quality tooling that can be used for the fabrication of several composite components.

Aluminum tooling was designed and fabricated for all the various components of the grille opening panels.

Photographs of the mold manufacturing process are shown in figures 100-110.
