This document presents the results of an eleven month water quality study in Lake Seminole located partially within each of three states: Georgia, Florida, and Alabama. Meterological, hydrological, sediment and physical, chemical, and biological water quality data were obtained at a total of 19 main sampling stations in Lake Seminole, the Chattahoochee, Flint and Apalachicola Rivers, Spring Creek and Fish Pond Drains during 7 sampling cycles from February through December 1979. Limited sampling and analyses were also performed at 5 special sites. Sampling and analytical methodologies are summarized and a

ABSTRACT

This document presents the results of an eleven month water quality study in Lake Seminole located partially within each of three states: Georgia, Florida, and Alabama. Meteorological, hydrological, sediment and physical, chemical and biological water quality data were obtained at a total of 19 main stations in Lake Seminole, the Chattahoochee, Flint, and Apalachicola Rivers, Spring Creek, and Fish Pond Drain during 7 sampling cycles from February through December, 1979 of Phase II. Limited sampling and analyses were also performed at 5 special sites. Sampling and analytical methodologies are summarized and a brief review and analysis of the findings are presented, including identification of major water quality problems and recommendations for future studies. Comparisons are also made to data collected during Phase I (April through November, 1978) of this study (For complete Phase I data see U.S.A.C.O.E., 1981). The detailed results of Phase II are included in attached appendices. Selected data were submitted to the EPA's STORET System.

OBJECTIVES

The overall objectives of the Lake Seminole Water Quality Management Study were to a) establish base line conditions for future comparisons; b) identify water quality-environmental problems; c) collect data to allow guidance for reservoir control-discharge water quality relationships; and d) collect data that will provide conditions to facilitate coordination with state agencies to implement watershed pollution control.

Those objectives were met by taking samples for physical, chemical and biological parameters in Lake Seminole and it major tributaries, the Chattahoochee River, and the Flint River as well the lake's outfall, the Apalachicola River. The samples were analyz using standard analytical techniques, and the selected data gen ed were stored in the Environmental Protection Agency's (EPA) Data Sto and Retrieval (STORET) system.

INTRODUCTION

Jim Woodruff Lock and Dam is located on the Apalachicola River at Mile 107.6 (173.2 km.), about 305 meters downstream from the point where the Flint and Chattahoochee Rivers unite to form the Apalachicola River. The structure is an earthfill dam with a concrete fixed - crest spillway, a center channel spillway with 16 vertical lift gates 12.2 m long and 9.3 m high and a side channel navigation lock 25 m wide. The dam crosses the Florida-Georgia border with about 457 meters of the overflow dike being located in Dacatur County, Georgia, and the remainder of the structure being in Gadsden and Jackson Counties, Florida. The primary purposes of the structure are to aid navigation in the Chattahoochee River upstream to the George W. Andrews Lock and Dam at Mile 47 (76 km.), in the Flint River to Bainbridge, GA about 48 km. upstream and downstream in the Apalachicola River, and to generate electric power. Other stated benefits include the regulation of streamflows, public recreation and fish and wildlife conservation. Construction of the project was initiated in September, 1947. The lock was opened for navigation, and impounding of water in the reservoir was begun in May, 1954. The power plant was placed in operation and the pool was considered full when it reach elevation 77 ft. (23 m) msl in February, 1957 (USACOE, 1972).

Lake Seminole, formed by the impoundment behind the Jim Woodruff Dam, is located partially within each of three states: Georgia, Florida, and Alabama as shown in Figure 1. The reservoir has a total drainage basin area upstream of the dam of 44,630 sq. km., of which approximately 51 percent is tributary to the Chattahoochee River and 49 percent tributary to the Flint River. The reservoir consists of two major impoundment arms, the Flint and Chattahoochee, and two minor impoundment arms, Fish Pond Drain and Spring Creek, both of which are tributary to the Flint River Impoundment. The reservoir has a surface area of 152 sq. km. and a total volume of 439 million cubic meters at the normal pool elevation of 77.0 feet (23 m) msl. The pool extends up the Chattahoochee River 75.2 km. to the George W. Andrews Lock and Dam and up the Flint River 76 km. (USACOE, 1972).

The Flint River has a total length of approximately 560 km. and a total drainage basin area of some 21,900 sq. km. The basin extends about 346 km. from north to south and averages roughly 64 km. in width. The headwaters of the Flint River are in the hilly region of the Piedmont Province, in the vicinity of the Atlanta Airport at an elevation of approximately 305 m. Seventy miles downstream from its source the river flows through the Pine Mountain District of the Greenville Plateau. The river through this stretch descends at a rate of approximately 0.04 percent up to the Fall Line at Flint River Mile 286 (460 km.). At the Fall Line the river drops rapidly over a shoal, and for 64 km. downstream. Downstream of Flint River Mile 220 (354 km.) the river flows

WATER QUALITY SAMPLING STATION LOCATION MAP FOR PHASE II (FEBRUARY, 1979 THROUGH DECEMBER, 1979)

through the Upper Coastal Plain of southwest Georgia until it joins the Chattahoochee River in the Lake Seminole impoundment (USACOE, 1976).

The average annual flow in the Flint River at Newton, Georgia (see Figure 1, insert) for the period of record 1938-1950 and 1956-1973 is 202 m^3/sec, with a minimum flow of 22.4 m^3/sec which occurred on both Oct. 20, and Nov. 10, 1940 and a maximum flow of 1870 m^3/sec which was recorded on March 9, 1966 (USGS, 1979).

The Chattahoochee River has a total length of approximately 1200 km. and a total drainage basin area of 22,700 sq. km. The basin extends about 410 km. from north to south. The headwaters of the Chattahoochee River are in the rugged, wooded Blue Ridge Mountains of Northern Georgia. Downstream from this area the river flows through the hills of the Piedmont Province which range in elevation from 366 m in the foothills of the Appalachian Mountains to approximately 183 m at the Fall Line. Downstream of the Fall Line the river flows through the Upper Coastal Plain until it joins the Flint River in the Lake Seminole Impoundment.

The Walter F. George Lock and Dam, located upstream of the Lake Seminole Impoundment on the Chattahoochee River at Mile 75 (121 km.) is operated as a peaking power plant and as a result there is considerable short term flow variation through the Chattahoochee River Impoundment of Lake Seminole. The average annual flow at Walter F. George Lock and Dam near Columbus, GA (see Figure 1, insert) for the period of record 1929-1978 is 192 m^3/sec, with a minimum flow of 8.3 cfs which occurred on Oct. 23, and Nov. 14, 1931 and a maximum flow of 4110 m^3/sec which occurred on Feb. 26, 1961 (USGS, 1979).

The Apalachicola River, now formed by the discharge from Jim Woodruff Dam, was originally formed by the confluence of the Flint and Chattahoochee Rivers in the extreme southwest corner of Georgia. The river is bounded on both banks by wetlands except for the upper 40 km. stretch which is bounded on the east by the Apalachicola River Bluff formation. The Mariana Lowlands extend from the western bank of the Apalachicola westward past the border of the basin and south to the Western Highlands which cut across the middle-western portion of the basin. The Tallahassee Hills occur on the eastern side of the Apalachicola from the Georgia border southward to the Coastal Lowlands. The Coastal Lowlands comprise the entire lower portion of the basin.

The river below Jim Woodruff dam decends at a rate of approximately 0.009 percent. The power plant at the Jim Woodruff Dam is a "run of the river" plant which operates around the clock except when occasional high flows reduce the available operating head causing the plant to be non-productive. There is no flood control storage available in the reservoir (USACOE, 1972). The average annual flow at the dam is 635.8 m^3/sec for the period of record Oct., 1928 to 1977, with a minimum flow of 140 m3/sec which occurred Oct. 27, 1954 and a

maximum discharge of 8300 m^3/sec which occurred on March 20, 1929 (USGS, 1978).

METHODS AND TECHNIQUES

Field Procedures

Sampling Site Locations

Sample site locations were specified by the U.S. Army Corps of Engineers (USACOE), Mobile District. The classification of sampling stations for the purpose of specifying field measurement, sediment and/or Corbicula sampling procedures was based in part on the total width of the cross section, the accessibility and submergence of the overbank areas as well as the inundation of the natural levees at normal pool stage. The sampling sites are shown on Figure 1, and their locations and their classifications as to river or lake station are tabulated in Table 1.

Sampling and Analytical Methodology

A complete sampling schedule showing the parameters sampled and sampling dates is shown in Table 2. A summary of the station parameter sampling schedule is shown in Table 3. A summary of the sampling methodologies, including respective maximum allowable holding times, sample container and preservation techniques as well as analytical methodologies employed and reported detection limits for the water quality parameters sampled during the course of this study can be found in Table 4.

Field Measurements

Dissolved oxygen (D.O.), pH, temperature, and specific conductance were measured at each station, one meter below the surface during every sampling cycle. To define the extent of the mixing within the river, D.O., pH, specific conductance and temperature were also sampled at depths of 0.33 meter below the surface and 1.0 meter above the river bed at midstream and within the littoral zone of both river banks at river stations 01 thru 07, 12, 14, 16, 17, 18 and 19 during the first and fourth sampling cycles (2/19-22/1979 and 7/16-19/1979). More extensive sampling including the measurement of Oxidation-Reduction Potential (ORP) at stations 7, 11 and 15 was performed during cycle 4 (7/16-19/1979) in order to develop complete cross sectional isopleths for these parameters. To define stratification, D.O., pH, specific conductance, temperature and ORP were vertically profiled at stations 07, 08, 09, 10, 11, 13 and 15 during all sampling cycles. Secchi disc and 1% light transmission measurements were also measured *in situ* at each station.

The field instruments used to sample the *in situ* parameters are listed in Table 4.

TABLE 3 (continued)

LAKE SEMINOLE WATER QUALITY MANAGEMENT STUDY
STATION SAMPLING SCHEDULE FOR PHASE II
(FEBRUARY, 1979 THROUGH DECEMBER, 1979)

NOTES:

1. See Table 2 for a Complete List of Parameters Sampled.
2. Unless otherwise noted, taken at mid-stream one meter below water surface or at mid-depth where total depth was less than 10 ft.
3. Unless otherwise noted, all parameters except ORP sampled 0.3 meters below water surface and 1 meter above bottom surface at mid-stream and left and right littoral zone during Cycles 1 (2/19-22/1979) and 4 (7/16-19/1979) only.
4. Originally scheduled to be sampled.
5. *Unless otherwise noted,* taken 1 meter above bottom during Cycles 3 through 6 only.
6. Unless otherwise noted, taken 0.3 meters below water surface.
7. Sampling at Station FE initiated during Phase I, Cycle 2 (6/5-7/1978).
8. Only Turbidity.

TABLE 4

LAKE SEMINOLE WATER QUALITY MANAGEMENT STUDY
WATER QUALITY PARAMETER STORET CODES, MAXIMUM HOLDING TIMES, PRESERVATION TECHNIQUES, ANALYTICAL METHODOLOGY AND DETECTION LIMITS FOR PHASE II (FEBRUARY, 1979 THROUGH DECEMBER, 1979)

STORET Code	Parameter	Holding Time	Container	Preservation Technique	Analytical Methodology	Detection Limit	Units
	I. Water Quality Sampling						
	Physical Data						
	Miscellaneous						
00077	Secchi Disk Transparency	None	--	(in situ)	#13, Secchi disk, 20 cm.	--	m
00034	Depth of 1% Surface Light	None	--	(in situ)	Protomatic Instruments underwater photometer	--	m

All field instruments (see below) are calibrated against standards or as specified and provided with spare batteries and/or chargers before being sent into the field. In addition, appropriate standard solutions were sent to the field with the instrument. All instruments were rechecked upon return; necessary maintenance and/or provision for storage was accomplished as specified by the instrument manufacturer. When in use, instruments were calibrated prior to beginning a set of measurements and at a minimum of four-hour intervals with a final check at the end. Verification of calibration was run after every 10 samples or if any unusual reading was encountered. Any anomaly was recorded.

Instrument	Routine Calibration
Dissolved Oxygen Meter	Air calibration as specified. Calibrated versus Winkler titration if problems were suspected or after any membrane change.
pH Meter	Battery check and calibration against commercially available certified buffers.
Conductivity Meter	Calibrated daily against KCl solution 0.01 demal as specified in manual. Any deviation in reading from manual specifications was recorded in notes.
Temperature Functions	Checked against mercury thermometer daily. Any deviation was reported in notes.
Current Meter	Circuit check. Daily check of zero. Yearly factory recalibration.

In situ measurements were recorded along with weather conditions in the appropriate section in the field data notes on carbonless duplicate field record as shown in Figure 2. The notes were checked for completeness before leaving each station, and initialed by the observer.

Water Quality Sampling

Unless otherwise noted, water quality sampling followed the schedules summarized in Tables 3 and 4. After the first sampling cycle of Phase I, special sampling station FE was located approximately 0.7 km. west of the location originally specified

because of the inaccessibility of the original site due to submerged navigation hazards. During the second sampling cycle, station 12 was not sampled due to mechanical boat problems.

All preservatives were added to the appropriate sample containers (with the exception of containers for spiked metal analyses) prior to being sent into the field. The actual spiking of spiked metal samples was also performed in the field.

Grab Samples. Grab samples for the water quality parameters listed in Table 2 were taken at midstream one meter below the surface or at mid-depth where the station depth was less than ten feet. In addition, to define the effects of stratification, grab samples were taken at midsection one meter above the bottom at sampling sites 07, 09, 10, 11, 13 and 15 (Table 3) for complete analyses from the third through sixth sampling cycles.

The samples were collected with either a 2-liter Wildco-Beta-Plus horizontal style water sampler or a 4-liter Wildco Alpha vertical style water sampler. The samples which require filtration such as dissolved metals, dissolved ortho-phosphate and dissolved organic carbon (DOC) were filtered immediately on the boat according to the method in Table 4. The samples were then distributed to the sample containers with the proper preservative as outlined in Table 4. The sample bottle numbers were recorded on a carbonless duplicate field bottle record as shown in Figure 3. After all the bottles had been recorded and checked, they were stored as specified in Table 4, in coolers either filled with ice at $4^{o}C$ or filled with dry ice for those samples which had to be frozen immediately.

Preservatives were added to most of the sample containers that require them prior to going to the field. However, the samples for the total and dissolved metals analyses, which require concentrated nitric acid (HNO_3) as a preservative were preserved in the field to reduce the amount of time the undiluted HNO_3 was in contact with the sample container. In addition, the samples used for dissolved organic carbon analyses had their preservative, sulfuric acid (H_2SO_4), added in the field to minimize the risk of organic contamination. Despite efforts to prevent any contamination in either the sampling, handling or preservation phases, a number of DOC sample values were greater than TOC values. All values were less than 10 mg C/l and in general the differences between DOC and TOC were 1 to 2 mg C/l. In all cases where DOC results were greater than corresponding TOC results, the DOC results were reported as "less than" the stated value.

Composite Samples. Composite samples for chlorophyll a, b, and c, phytoplankton, dry biomass, adenosine triphosphate (ATP), and algal growth potential were obtained by collecting a depth integrated raw water sample from either the euphotic zone, defined as the zone above the 1% light transmission level, in quiescent waters (lake stations) or from the entire water column in more turbulent waters (river stations). Samples were taken using a horizontal beta water sampler

##Split sample station only

at the surface and at one meter intervals until the lower limit was reached as determined above. The samples were then composited and the required aliquots for the various parameters were drawn. When the depth to be composited was greater than seven meters, samples were taken at the surface and equal spaces over the required sampling depth.

Bacteriology Sampling and Analysis

Bacteria grab samples were taken (Table 3) in two 100 ml autoclaved sample bottles at a depth of 0.3 meters below the water's surface. Analyses for fecal coliforms and fecal streptococci were run in the field according to the method shown in Table 4. Precision control was tested by duplicating the first station of each day. Results were considered consistant if the 95 percent confidence intervals for both replicates overlapped.

Sediment Sampling and Analysis

Sediment samples were collected at each station listed in Table 3 and analyzed by the method referenced in Table 4. Each station was sampled at mid X-section station location with an epoxy coated Ponar™ dredge (standard size, 9"/side). If rock was encountered such that a grab could not be obtained, a sample was obtained at another point along the X-sectional location at that station. All samples were stored as specified in Table 4.

Corbicula Sampling

Corbicula specimens were taken where available utilizing an epoxy coated Ponar™ dredge (standard size, 9"/side). A minimum of four grab sampling attempts were made at each of those stations specified in Table 3. Samples were taken at four equally spaced locations across the channel at river stations and at four locations, 90-degrees apart, along an imaginary 20-foot diameter circle at lake stations. Recovered specimens were washed prior to storage as specified in Table 4.

Other Field Sampling & Processing

Field sampling and processing methods for the algal growth potential test, phytoplankton, zooplankton, ATP, macroinvertebrates and macrophytes are discussed in subsequent sections of this report.

Storage and Shipment of Samples

All preserved water and sediment samples were stored as specified in Table 4 in coolers filled either with ice to 4°C or with dry ice for freezing. At the end of each sampling day, the samples were sent to the Water and Air Research, Inc. (WAR) lab in Gainesville via special courier, along with copies of the field notes from that day.

Laboratory Procedures

Chemical Parameters

Sample Integrity. The integrity of all samples was maintained from the moment they were received in the laboratory until the data were reported and approved. All samples were "logged in" immediately upon receipt. When feasible, preservation was also checked. Project name, parameters, sample number, and date received were recorded both in the log and on appropriate forms in the project notebook. A control sheet was used to monitor work in progress. Samples were stored as specified according to the analyses to be run, normally either frozen or at 4°C.

Samples sent to outside laboratories were also recorded as above. Date and shipping information were recorded in the project notebook. Documentation of shipment was preserved as part of the permanent laboratory record. A tabulation of bottle numbers accompanied any samples so sent. Spiked samples and duplicated samples were routinely included in the shipments as a quality control check. These control samples were not specifically identified to the subcontractor.

Analytical Methods. Chemical analyses of water, sediment, and mollusk tissue as well as bacteriological analyses of water strictly adhered to the procedures listed in Table 4. Any deviation from these specifications has been noted with the reported data.

Notes and Record Keeping. When the samples reached the laboratory, they were "logged in" immediately by date in the permanent laboratory record in a color-coded permanent project notebook. Each station was given a unique four-digit laboratory number. All notes, analysis sheets, printouts and any other lab information relative to the Lake Seminole project were also kept in the project notebook. Verification of the bottle numbers for each station by comparison with the field record was the responsibility of the lab supervisor. A tabulation of sample identification by laboratory code number, bottle number, and station number including the date sampled and the date received became a part of the permanent record. A table was made to monitor the status of the analytical effort on a given set of samples.

Analytical data sheets by analysis were prepared for groups and individual samples. These were marked with the sample identification number(s), project, date sampled, date received, and date analyzed. All analytical readings and calculations appear on these data sheets. These were turned in daily and filed in the appropriate project notebook. Any unusual appearance of the samples or results was recorded on the data sheets. These data became a part of the permanent record. All data sheets were initialed by the analyst and calculator. Recorder printouts such as autoanalyzer charts or fluorometer records were labeled according to parameter, project, date sampled and date analyzed and accompanied the data sheets which have been kept as a part of the permanent record in the project notebooks.

Sub-contracted Analyses. The list of analyses given in Table 5 were sub-contracted. Liason with each sub-contractor assured that the methods specified in Table 4 were followed in every case. Sample integrity records were maintained and spiked and duplicated samples were included in each shipment to provide quality control independent of the sub-contractor. Reports of results including quality control results were entered as a part of the permanent laboratory record. The laboratory supervisor was responsible for monitoring the analytical performance of each sub-contractor.

Calculation and Reporting of Data. Calculation of the results of analyses was accomplished as soon as possible following completion of the "hands on" work to facilitate assessment of the control exercised by standards, replicates, and spiked samples. This assessment was the responsibility of the laboratory supervisor. All calculations were shown on the analysis sheets as part of the permanent laboratory record.

Checking calculations either by the analyst or the data calculator was standard practice. It was the responsibility of the laboratory supervisor to insure that all data reported had been calculated correctly.

"In-house" data tabulations and data were stored in the project notebooks as a part of the permanent record. Notes pertaining to field data, anomalous results, or deviations from standard methods were appended to finished reports. The accuracy of such reports was the responsibility of the laboratory supervisor.

For each cycle, the complete laboratory data base was tabulated on computer coding sheets and reviewed. These sheets were turned over to the project manager for entry into the data storage-retrieval system. A xerox copy of these sheets was kept in the project notebook as a part of the permanent laboratory record.

Quality Control Assurance

The following paragraphs describe the methods and procedures employed to assure the accuracy of the field measurements and laboratory chemical water analyses results. Short cuts were not permitted and any abnormalities were brought to the attention of the laboratory supervisor immediately. This included any analytical or safety abnormality as well as instrumental malfunction, or problems in replication or spike recovery.

Calibration Checks. These checks were done before using any instrument and the calibration recorded on the analytical data sheet. Daily logs of oven, refrigerator, and incubator temperatures were maintained with this equipment.

Gravimetric Analysis. Accuracy of analytical balances was monitored with a standard weight set (coins) and results were recorded on log sheets. Calibration checks and routine maintenance is done biannually by an established contractor.

Titrimetric Analyses. The method was checked against a standard solution daily. The results were recorded on the data sheet and as part of the accuracy control data.

Colorimetric Analyses. A standard curve of at least 3 points was run daily. More points were run if required. The results of standards were recorded on the data sheet and also as a part of the accuracy record.

Instrumental Analyses. The Atomic Absorption Spectrophotometer and the Technicon Autoanalyzer II had daily calibration curves constructed. Instrument settings were recorded on the data sheet and as a part of the instrument record.

Fluroide electrodes, pH meters, conductivity meters, and turbidimeters were calibrated as necessary and the calibration was checked after every 10 samples. The notation was entered on the data sheet that the calibration was made.

The laboratory deionized water supply's resistance was continuously monitored and maintained at 500,000 OHMS. Deionized water blanks were always included in analyses to control possible contamination from this source.

Precision and Accuracy Control. Shewhart type (USEPA, 1979) precision and accuracy control charts were maintained for all routine laboratory analyses. These charts are updated yearly using the entire data base generated by the laboratory for the preceding year's work. These charts were maintained as a permanent laboratory record.

In this study precision was also monitored by analysis of duplicate samples. A minimum of 10 percent of the total number of samples obtained during a given sampling cycle were split in the field by filling two separate containers from the same grab sample. In general, this was achieved by sampling one station in duplicate on each sampling day. One of this pair of samples was analyzed as the first sample of an analysis run; the other was run as the last analysis. An additional sample was duplicated within a given analytical set. The difference between the field duplicates was compared with the control limits on the quality control chart. If the difference exceeded the warning limits the difference between the in-house duplicate was compared. If the in-house and field differences exceeded the warning limits the whole set of analyses was repeated. If the field duplicates exceeded the warning but the in-house duplicate was in control, each of the field duplicates was run again to verify that the difference was due to sampling rather than analytical procedure.

The results of the field duplicated samples was included in each progress report and as Appendix E in this report. The sample duplicated in-house was recorded on the precision chart.

Daily monitoring of the accuracy of the analytical work was accomplished by comparing the results of recovery of known spikes from replicated spiked samples. One sample in every 10 was spiked and at least one spiked duplicated sample was included on each sample set. The difference between the recovered value for the spike versus the normal spike value was compared with the accuracy chart warning limit. If this value exceeded the warning limits the analysis for the set of samples was repeated. The results of the spike recoveries were recorded on the accuracy chart.

Spiked sample analyses were run for:

- Fluoride
- All nitrogen forms
- All phosphorus forms
- Sulfate
- Chlorides
- All metals.

In addition, two samples each sampling cycle were spiked in the field with iron, manganese, and zinc. Samples for dissolved metals for these same stations were spiked with iron and manganese. The spiked samples for total metals were split with the South Atlantic Division Laboratory (SAD). Results of these metal spike recoveries were included in each progress report.

In addition to the in-house accuracy control, quality control assurance was monitored by splitting two samples per cycle with the SAD laboratory.

Reference Samples. Environmental Protection Agency reference samples for chlorophyll a, b, and c, nutrients, BOD, major ions, and trace metals were analyzed during cycle 3 and the results compared to established values.

Bacteriological Quality Control. Control of the quality of bacteriological media was maintained by careful attention to holding times and conditions for prepared m-fecal coliform broth (96 hours at 4°C) and KF-streptococcus agar (one month at 4°C). Sterility of sample bottles and equipment was assured by monitoring autoclaving time and temperature. A heat sensitive test strip was included in each set of autoclaved material.

In the field, attention was paid to meeting holding times for bacteriological samples. Incubator temperatures were carefully monitored. One sample each day was analyzed in duplicate.

Algal Growth Potential Test Methodology

The algal assay procedure, bottle test, was performed on water

collected from 11 selected stations (06, 07, 09, 10, 11, 12, 13, 14, 15, 16 and 18) during sampling cycles 2 (4/2-4/1979), 4 (7/16-19/1979) and 6 (9/24-26/1979) in accordance with procedures specified in Miller et al. 1978. Algal growth response was indirectly measured as ash-free dry weight after 12 and 14 days incubation using a Coulter Model Z_f particle counter equipped with a near cell volume computer. The counter and cell volume computer were calibrated in accordance with the manufacturer's procedures using a 4.59 μ diameter organic particle obtained from Coulter Electronics, Inc. All counts were run using a lower threshold of 10 μm^3 to exclude debris. Calibration of the mean cell volume computer was performed each time the instrument was used. Procedures for calibrating Coulter type electronic particle counters are also included in Miller et al. 1978. A gravimetric factor to convert particle volume to ash-free dry weight was determined to be 2.8×10^{-7} μg μm^{-3} for Selenastrum capricornutum Printz under the culture conditions used. Five counted, sized suspensions were washed three times by centrifugation, transferred to tared crucible cups and dried at 70°C overnight. After weighing the dried algae, the ash content was determined after heating the material at 500°C for 1 hour. A subculture of this organism supplied from the Pacific Northwest Environmental Research Laboratory (EPA) on 4/4/78, was maintained for use during each of the algal assays.

Depth integrated samples from the euphotic zone in quiescent waters (lake stations) or from the entire water column in more turbulent waters (river stations) were collected as specified earlier. All samples were processed within three days by an autoclaving-filtration procedure to assess the amount of algal biomass which could be grown from all nutrients in the water, including those contained in filterable organisms and other particulate matter (Miller et al. 1978). Background chemical analyses for total Kjeldahl nitrogen, ammonia nitrogen, nitrite plus nitrate nitrogen, as well as dissolved ortho-phosphate and total phosphorus were performed on the samples before and after autoclaving.

The experimental design shown in Table 6 was followed to determine the nutrient availability, the primary growth limiting nutrient(s) (nitrogen, phosphorus, or trace metals) and to determine the presence of toxic substances. This procedure, outlined in Miller et al. 1978, compares the relative growth of the test alga in water spiked according to Table 6 to the growth response of the alga in unspiked lake water. Each combination as well as the lake water control was set up in triplicate for each station.

Phytoplankton Methodology

Phytoplankton was collected from a depth integrated raw water sample from the euphotic zone in quiescent waters (lake stations) or from the entire water column in more turbulent waters (river

TABLE 6

LAKE SEMINOLE WATER QUALITY MANAGEMENT STUDY
BASIC EXPERIMENTAL DESIGN USED TO DEFINE
NUTRIENT LIMITATIONS AND ALGAL GROWTH
POTENTIAL FOR PHASE II (FEBRUARY, 1979
THROUGH DECEMBER, 1979)

Lake water (not spiked)

Lake water + 0.05 mg P l^{-1} as K_2HPO_4

Lake water + 1.00 mg N l^{-1} as $NaNO_3$

Lake water + 0.05 mg P l^{-1} + 1.00 mg N l^{-1}

Lake water + 1.00 mg Na_2 EDTA l^{-1} as Disodium (Ethylenedinitrilo) tetraacetate

Lake water + 0.05 mg P l^{-1} + 1.00 mg Na_2 EDTA l^{-1}

Lake water + 1.00 mg N l^{-1} + 1.00 mg Na_2 EDTA l^{-1}

Lake water + 0.05 mg P l^{-1} + 1.00 mg N^{-1} + 1.00 mg Na_2 EDTA l^{-1}

stations). The water sample was depth integrated with a Van Dorn™ sampler just below the surface and at one meter depth intervals until the lower limit was reached. If the euphotic zone in quiescent waters or impoundment depth in more turbulent waters was over 7 meters deep, eight samples beginning at the subsurface were equally spaced over the required sampling depth. These were composited and a 1 liter aliquot for the station withdrawn, placed into a pre-numbered 1 liter plastic jar, and preserved with 5 percent buffered formalin (neutralized with sodium tetraborate to a pH of 7.0 to 7.3). The collection number, site, date, and time of collection were recorded for each station in a field notebook along with weather (cloud cover, wind direction, and intensity) and water conditions (surface waves, color, turbidity, and depth) and any unusual observations during sampling.

In the laboratory, the field data were transferred to a permanent log book and the samples checked against this record. Phytoplankton analysis was made by the Utermöhl (1931, 1958) method. Each sample was resuspended with a magnetic stirrer and a known aliquot (usually 20 or 40 mls) was transferred into a standardized plankton sedimentation chamber with a known settling area of 397.6 mm^2. After 24 hours of settling, the chamber was placed on a Zeiss Invertoscope "D" microscope (magnification to 1000X), and a minimum of 150 organisms were enumerated for each sample. Cell counts were made by randomly selecting microscope fields along at least two perpendicular transects of the chamber and counting all cells within each field. For colonies and filaments consisting of a large number of cells, 1/4 or 1/2 of the colony or filament was counted and this resultant number multiplied to obtain the number of cells for the entire colony or filament. Empty algal cells or diatom frustules were not included in the counts. Identified cells were recorded on standardized bench sheets and later converted to number of cells per milliliter for each taxon in the water sample using the following conversion equation:

$$\text{Cells/ml} = \frac{(CA)}{(FMV)}$$

where,

C = number of cells counted;
A = area of bottom of the counting chamber (397.6 mm^2);
F = number of fields counted;
M = area of one microscope field (0.038 mm^2); and
V = volume of aliquot settled.

All organisms were separated and identified to species where possible. The following major standard taxonomic references were used for identification: Heurck, 1896; Hustedt, 1927-1930, 1930, 1931-1959, 1949, 1961-1966; Hanna, 1933; Huber-Pestalozzi and Hustedt, 1942; Smith, 1950; Prescott, 1951; Drouet and Dailey, 1956; Bourrelly, 1966-1970; Patrick and Reimer, 1966, 1975; VanLandingham, 1967-1979;

Drout, 1968, 1973; Whitford and Schumacher, 1973. Other minor references too numerous to list were also used.

Since the classification of diatoms is based primarily on the shape and markings of the cell wall, critical identifications can only be done if the diatoms are cleaned (all organic matter removed); thereby leaving only the silica cell walls. Diatom identification was facilitated by cleaning 30 ml of the initial samples using the hydrogen peroxide method (Werff, 1953; Patrick and Reimer, 1966). This involved placing the aliquot in a 2,000 ml beaker and adding approximately 50 ml of 30 percent hydrogen peroxide. A small amount (0.1 - 0.2 g) of potassium dichromate was added (resulting in a purple solution) and in a few moments an exothermic reaction began. This resulted in a violent heating and boiling of the mixture, which oxidized all of the organic matter within the solution, including that contained within the diatoms.

Upon completion of this aqueous combustion reaction, the solution turned yellow and the mixture was then transferred to a 300 ml tall beaker, filled with distilled water, and allowed to settle 6 - 24 hours. The diatomaceous material settled to the bottom and formed a delicate flocculent layer. The sample was then decanted at least 3 times to remove the chemicals (using distilled water to refill the beaker after each decanting). The cleaned diatoms were then poured into a storage vial and enough alcohol added to make at least a 30 percent solution to inhibit growth of *fungi*.

Permanent slides were made of the cleaned diatoms with Hyrax mounting medium. Clean #1 cover slips (22 mm sq) were flooded with water containing different concentrations of the suspended diatoms and allowed to air dry at room temperature or on a low temperature hot plate. When dry, the coverslip was heated to 500°C for 5 - 10 minutes and then inverted into a drop of Hyrax on a slide. The slide was then heated for a few minutes at 300 - 400°C until the Hyrax stopped bubbling under the coverslip. This allowed time for the penetration of the diatom frustules by the Hyrax and the evaporation of the solvent. The slide was then allowed to cool while pressing the coverslip down so that it would lie flat on the slide. The Hyrax hardened rapidly and the excess along the edges was scraped off with a razor blade. The slide was then wiped clean with acetone. Initial diatom identifications were made from these slides. If identification difficulties arose in other samples during the study period, portions of these samples were also cleaned and permanent slides made to facilitate diatom identifications.

Voucher specimens of difficult taxa were sent to Dr. C. W. Reimer, Academy of Natural Science of Philadelphia (diatoms) and Dr. J. B. Lackey, Professor Emeritus, University of Florida (green and blue-green algae) for taxonomic verification. Additional outside taxonomic checks were made by the U.S. Army Corps of Engineers, Mobile District, Mobile, Alabama.

Zooplankton Methodology

Semi-quantitative zooplankton samples were collected from quiescent waters (lake stations) with a single vertical tow through the water column by using a Wisconsin style 0.5 meter diameter, 80 micron mesh weighted plankton net with an attached flowmeter. The tow was performed at a uniform speed of approximately 0.5 meter per second to minimize avoidance reactions and sampling bias. Zooplankton were collected from turbulent waters by taking an oblique tow from near the bottom to the surface while letting the boat drift with the river flow to maintain a tow angle as nearly vertical as possible. The tow angle, time, length of rope let out, and flowmeter readings were recorded. Zooplankton samples were preserved in a final concentration of 5 percent buffered formalin with Rose Bengal added in pre-numbered plastic bottles. The collection number, site, date, and time of collection were recorded for each station in a field notebook, along with weather (cloud cover, wind direction, and intensity) and water conditions (wave height, color, turbidity, and depth) and any unusual observations during sampling.

In the laboratory, the field data were transferred to a permanent log book and the samples were checked against this record. Zooplankton were identified on a compound microscope with a magnification to 400X. They were then enumerated by placing a thoroughly mixed aliquot in a Wards zooplankton counting wheel and examining it at a magnification of 20 - 60X under a stereoscopic microscope. The aliquot size (taken with a Henson-Stempel pipet) varied from 1 - 5 ml depending on the densities of organisms and detritus. All zooplankton within the chamber were identified to genus wherever practicable and enumerated except for the two dominant genera which were identified to species.

The principal taxonomic references utilized were Edmondson, 1959; Brooks, 1957; Deevey & Deevey, 1971; Marsh, 1929; and Voight, 1956. Taxonomic checks were made by the U.S. Army Corps of Engineers, Mobile District, Mobile, Alabama.

The number of each taxon in the sample was converted and reported as number per liter using the following conversion equations:

$$\text{Number of organisms/l} = \frac{AC}{BV}$$

where,

C = organism count (raw data)
A = volume of the concentrated sample;
V = volume of water passed through the plankton net; and
B = volume of the examined aliquot.

The total volume (V) was calculated as a function of the length of the water column which the net passed through:

$$V = \pi r^2 l = (3.14)(0.25\ m)^2 l = 1\ (0.196\ m^2)$$

with l being the length of the water column based on the flowmeter value or the length of rope let out if the flowmeter malfunctioned.

ATP Test Methodology

Sampling and Sample Preparation

At stations 01 through 19, 200 ml or more of water from the depth integrated water sample were filtered through a 0.45 µm membrane filter (Millipore). Upon completion of the filtration, the vacuum was broken just as the last of the water passed through the filter, and the filter was quickly transferred to a 150-ml Pyrex beaker containing 10 ml of boiling 0.02 M Tris buffer. The filter was placed upside down into the Tris and heated for 5 to 10 minutes at 100°C in a water bath. The beaker was then removed from the water bath, the filter scraped with a plastic policeman to loosen the filtrate from the filter into the Tris, and replaced in the boiling water for 5 min. The beaker was then removed from the water bath and cooled rapidly. The filter was held against the side of the beaker and any remaining filtrate scraped off with a plastic policeman. The filter was then discarded. The sample was then transferred to a 1-oz Nalgene (plastic) screw cap bottle, labeled with the bottle # (T___) and volume (mls) filtered, and frozen at -20°C (dry ice in the field).

When the sample was ready to be analyzed, the contents of the bottle were thawed, the sample mixed and then transferred to a centrifuge tube. The volume of sample was recorded and approximately half of the sample was transferred back to the original container (in case of errors such that a redetermination was necessary) and the remainder centrifuged. The tubes were removed from the centrifuge and the supernatant poured into a clean, labeled scintillation vial for transport to the University of Florida for determinations.

Standardization Curve

An ATP standard stock solution was prepared by weighing 119.3 mg of crystalline adenosine 5' - triphosphate-disodium salt using ATP-free glassware. The ATP was dissolved in 100 ml of fresh 0.02 M Tris buffer containing 29.2 mg of EDTA and 120 mg of $MgSO_4$ (resulting concentration of 1 mg of ATP/ml). This was dispensed in 5.0 ml aliquots in 1-oz Nalgene bottles and stored at -20°C until required.

One ATP stock bottle was thawed and 1.0 ml of the ATP stock solution containing 1 mg of ATP/ml was pipetted into a 1-liter

volumetric flask and brought up to volume with 0.02 M Tris buffer (or pipet 1 ml of stock solution into 100 ml of Tris, mix, and pipet 1 ml of this dilution into 9 ml of Tris to result in the same dilution). This solution contained 1.00 µg ATP/ml. The following serial dilutions were then made:

1.00×10^{-1} µg ATP/ml
1.00×10^{-2} µg ATP/ml
1.00×10^{-3} µg ATP/ml
1.00×10^{-4} µg ATP ml.

The calibration curve was determined by making a minimum of 3 replicate determinations of each of the serial dilutions.

Reagents

Tris Buffer: (0.02 M) (Tris (Hydroxymethyl) Aminomethane) - Dissolve 2.5 g of the buffer crystals in 1 liter of deionized water. Bring to pH 7.75 using HCl (pH meter). Sterilize by autoclaving for 30 min. at 121°C, 15 psi (103 kPa) pressure, and store refrigerated in stoppered flasks.

FLE-50: Firefly Lantern Extract (Luciferase/Luciferin Reaction Mixture) - Reconstitute by adding 35 ml (or 37.5 ml) of low response water to one vial of extract. The luciferase/luciferin reaction mixture must be mixed gently without shaking. Allow to stand at room temperature (23 - 26°C) for one hour. Filter through Whatman #1 filter paper and store in an ice bath for 3 hours before use. Use enzyme preparation within 8 hours of preparation.

Hydrochloric Acid (0.2 N): Add 17.0 ml of HCl (sp. gr. 1.19) to a 1-liter volumetric and bring to volume with water.

ATP-Free Glassware: Rinse chemically clean glassware three times with 0.2 N HCl, rinse three times with Tris buffer, and rinse three times with low-response water.

Low-response Water: Sterile, deionized, ATP-free water may be prepared by treatment in a suitable system involving carbon treatment with deionization, filtration, glass distillation, or sterilization by autoclaving and stored under refrigeration in stoppered flasks.

Determination

One ml of reconstituted firefly lantern extract (35.0 ml low response water/vial of extract) was pipetted into a scintillation vial and the background light emission read. Using a Packard Tri-Carb Model 2002 liquid scintillation spectrometer (gain set at 53, window opening of 50 to 1,000, and set in a repeat count mode, with each

sequence) the normal background emission was 10 to 20 counts or less in the 6-sec counting interval.

Exactly 0.5 ml of the ATP standard or sample extract was added using the micropipette syringe (with new tip each time) and the vial swirled to thoroughly mix the contents. Eleven seconds after the sample addition to the firefly extract, the vial was inserted into the counting chamber and the counting sequence begun. Two samples from the beginning of the run were repeated at the end of each run to determine repeatability and check for decay of the firefly lantern extract during the run. For each cycle in Phase II, samples were analyzed for each of the 19 stations except during the last two cycles due to the loss of eight samples from September and eleven samples from December. These samples were inadvertently disposed of during storage before the analyses were done.

Macroinvertebrate Methodology

Benthic Natural Substrates

Benthic macroinvertebrate grab samples were collected at all nineteen locations. Sampling frequency was as outlined in Table 2 At the riverine stations, one sample was collected in the thalweg and one near each river bank. At lake stations 08, 09, 10, 11 and 13 samples were collected from three locations, taken 120 degrees apart, along an imaginary 20-foot diameter circle.

Benthic macroinvertebrates were collected with a standard size (9"/side) Ponar™ dredge. The dredge was lowered from the side of the boat, using a boom and power winch, slowly enough that a minimal "shock wave" was created so as not to disturb the benthos. Once the dredge touched bottom, the closing mechanism was immediately tripped and the dredge quickly raised to the surface. The dredge was then placed in a sieve bucket (US Standard No. 30 mesh) and the sample washed out with a squirt bottle filled with lake (or river) water to reduce the sample volume. The washed sample was then placed in a pre-numbered bottle (wide mouth, plastic, 1-pint or 1-quart).

Upon completion of all replicate sampling at a given station, buffered formalin preservative was added to a concentration of 5-10 percent, depending upon the quantity of detritus present. Rose Bengal was added as an organism stain to facilitate sorting, being added prior to preservation in order that the organisms' respiratory processes increased the amount of staining. The rose bengal was applied as a dry crystal, in a quantity sufficient to stain the sample a dark red, this quantity being variable according to sample size and the amount of detritus in the sample.

Upon return to the lab, the samples were shelved in an orderly manner and their numbers recorded and checked against the numbers in the field notes. Samples which were accidentally misrecorded, or which were otherwise in error, were discarded.

In the laboratory, each sample was carefully washed in a US Standard No. 30 mesh sieve (or smaller, if organism loss was significant) that was partially immersed in a large white plastic pan. This removed formalin, excess Rose Bengal stain, and the remaining silt and clay. The sample was then placed, in manageable aliquots, in a white enamel pan for removal of organisms (sorting). Organisms were placed in 5 milliliter vials in 95 percent ethanol. Each vial was labeled with a code representing the project, collection date, type of substrate sampled, collection location, and replicate bottle number. For example:

LSN-3-18E

Project Code and Substrate	-- Collection Date	-- Station No.
(Lake Seminole, Natural Substrate)	(third cycle: June 1979)	(18 East Bank)

A vial with ethanol was weighed, the sampled organisms were then placed in the vial, and the vial was re-weighed. The difference between the two values was considered "wet weight" biomass. These numbers are high, however, due to the introduction of extra ethanol when inserting the organisms. Limited experiments suggesting errors as high as 25-33 percent were found at stations with relatively low biomass.

Organisms were identified with an American Optical Stereoscopic Microscope (7X to 80X) and a Swift Trinocular Microscope (40X to 400X). Taxonomic references used were Beck (1962, 1976), Beck and Beck (1969a and b; 1970), Curry (1958), Hilsennoff (1975), Mason (1973), Parrish (1968), Roback (1963, 1969), Brinkhurst and Jamieson (1971), Brown (1972), Edmunds, et al. (1976), Holsinger (1972), Thompson (1968), Usinger (1956), Wiggins (1977), and Saether (1977). Taxonomically difficult and ecologically important species were identified or verified by experts in their respective fields: William Beck, Florida A&M University, for Chironomidae and Michael Loden, Louisiana State University for Oligochaeta. Other authorities were consulted for the less frequent taxa, and for specific groups within the Insecta (such as Dr. Minton J. Westfall, University of Florida, for Odonata). Additional outside taxonomic checks were made by the U.S. Army Corps of Engineers, Mobile District, Mobile, Alabama.

The Chironomidae and Oligochaeta were grouped under low magnification and representative specimens were selected for microslide mounts, from which the identifications were made. Only one organism was mounted per microslide. Chironomids were mounted in polyvinyl-lactophenol, which contains a clearing agent and makes excellent semi-permanent slides. Oligochaetes were permanently mounted in Coverbond™, which does not contain a clearing agent. Organisms can be removed and remounted, if necessary, with either of these mounting media.

The Shannon-Weaver Species Diversity Index, $\bar{H}$ (Odum, 1971) was calculated using the following expression:

$$\bar{H} = \sum_{i=1}^{t} \left[\frac{n_i}{N} \log_2 \left(\frac{n_i}{N} \right) \right]$$

where n_i = total number of organisms present as taxon i

$N = \sum_{i=1}^{t} n_i$ = total number of organisms present in the sample

t = number of taxa present in the sample

$\bar{H}$ ranges from a minimum of 0.0, occurring when all organisms belong to the same taxon (no diversity), to a maximum of $\log_2 N$, occurring where each organism present belongs to a unique taxon (maximum diversity).

Evenness (e)

If the organisms of a sample are uniformly distributed among the taxa present, the Shannon-Weaver Index assumes the value, ln t, a condition of perfect evenness in the apportionment of individuals among species. The Index of Evenness, e (Odum, 1971) was used to express the actual Shannon-Weaver Index as a fraction of this "ideal" value:

$$e = \frac{\bar{H}_e}{\ln(t)} \quad \text{(defined for } t > 1\text{)}$$

where $\bar{H}_e$ = actual Shannon-Weaver Species Diversity Index

t = number of taxa present in the sample

Evenness ranges from 0.0 (minimum evenness) to 1.0 (perfect evenness), and the calculated values are independent of the logarithmic base.

All samples were retained for reference until being sent to the Mobile District COE office at the end of the study. A few chironomid larvae and oligochaetes were donated to Mr. William Beck, Jr., and Dr. Michael Loden, for their taxonomic value.

Hester-Dendy Artificial Substrates

The Hester-Dendy sampler used was that which is recommended for EPA biologists. It consists of fourteen 7.5-cm diameter plates, and twenty-four 2.5-cm diameter spacers, constructed of 0.625-cm thick tempered fiberboard, strung together on a 25-cm eyebolt so that there are 8 single spaces, one double space, two triple spaces and two quadruple spaces between the plates. This sampler has an effective surface area of 0.12 square meter.

Artificial substrates were emplaced at all stations except 08, 10, and 17. The samplers were attached to marker buoys and incubated for a period of six weeks. The sampling frequency is outlined in Table 2. Each sampler was collected by raising it from the water and quickly placing it into a cloth bag, which was then preserved in a 5-gallon Roper™ bucket containing a 10 percent buffered formalin solution. These samplers were not re-used, as it was very difficult to remove the formalin from the fiberboard.

In the laboratory, the cloth bag was everted into a US Standard No. 30 mesh sieve placed in a white enamel pan. The sampler was then removed and disassembled. The bag, sampler, and organisms were rinsed to remove the formalin and accumulated sediments. All organisms were removed and placed in vials containing 95 percent ethanol. Each vial was labeled and the organisms identified as outlined in the previous section.

Shannon-Weaver and Evenness values for the Hester-Dendy macroinvertebrates were calculated as described above.

Macrophytes

Aquatic macrophytes in Lake Seminole were surveyed in June and September, 1978 and in April and August, 1979. The macrophyte surveys were conducted to map their extent, to obtain pressed specimens, to collect reference photographs, to develop species lists, and to determine their nuisance potential.

The reservoir was surveyed from a flat-bottomed boat for 3-4 days during each of the four field trips. Included were personnel from WAR and USACOE personnel at Lake Seminole. The vegetation map was

constructed from notes collected during field inspections. Specimens of selected "uncommon to rare" species were collected when in flower. These were pressed and duplicate herbarium sheets were prepared for delivery to the USACOE personnel at Mobile, AL. Reference photographs were taken in 35 mm color slide form and are being held at WAR. Species identifications and lists were made *in situ* by survey personnel. The primary taxonomic references were Radford, *et al.* (1964), Long and Lakela (1971), and Fassett (1940). The nuisance potential of aquatic macrophytes in the lake was determined by interviews with USACOE biologists, local residents, USACOE publications (USACOE; 1961, 1971, 1972, 1973, 1974, 1975, 1977a, 1977b, 1978), and by inspection.

The vegetation map was very difficult to construct for several reasons. First, appropriate aerial photography, which is the single most important tool for mapping vegetation, was unavailable. Second, the USGS Quadrangle maps, which were relied upon in lieu of aerial photos, are incorrect in many places, especially concerning the reservoir islands. Third, vegetative diversity is very high. And fourth, mapping the dense periphyton mats occurring in the shallow waters of the Flint River portion of the reservoir is dependent on the use of bottom topographic maps, which were unavailable to us.

Several compromises were made as a result of these problems. Shoreline vegetation, usually a mix of several to many species, was not shown in many places since it occurs in too narrow a band to show in tne chosen map scale. This problem was most pronounced with the fringe of giant cutgrass around many islands and in the Chattahoochee River. Also, small patches of invading nuisance species, such as *Egeria* at the Georgia Ranger Station, are too small to show up in the chosen map scale. The periphyton mats are not shown at all.

RESULTS AND DISCUSSION

The following discussion is intended to summarize the data shown in Appendices A through M and highlight the trends and water quality observed during the seven sampling cycles of Phase II of the Lake Seminole Water Quality Management Study. Brief references and comparisons are also made to the data from Phase I (1978 data) where appropriate. For greater detail on Phase I results and discussion, see U.S.A.C.O.E., 1981.

Stream Flows

Data was obtained from the United States Geological Survey (USGS) in Doraville, Georgia, for the Flint River at Newton, Georgia (USGS Station 02353000) and the Ichawaynochawa Creek (a tributary of the Flint River) at Milford, Georgia (USGS Station 02353500). The location of the flow gaging stations are shown on the Map Coverage Index of Figure 1. Data for the flow through Jim Woodruff Lock and Dam and Walter F. George Lock and Dam were obtained from the U.S. Army Corps of Engineers, Mobile District. The data for Ichawaynochaway Creek, the Flint River, and the Chattahoochee River Stations represent flows outside the actual study area.

A summary of the available stream flow data is given in Appendix A. Monthly average stream flows for which there are data are shown for the Chattahoochee and Flint Rivers, Ichawaynochaway Creek, and the flow through Jim Woodruff Lock and Dam. Daily averages for one week prior to and the week of each sampling cycle are also shown.

In general, the data shows wide variations in flow from day to day on the Chattahoochee River due to fluctuations in discharge from Andrews Lock and Dam. The Flint River is not subject to these wide daily variations. Based on monthly average flows, the Chattahoochee accounted for approximately 50 to 70% of the total flow reaching Lake Seminole.

The period of highest flow occurred during sampling cycle 2 in April. Monthly average flows for April 1979 were 849 m^3/sec at Walter F. George Lock and Dam on the Chattahoochee, 368 m^3/sec on the Flint River at Newton, Georgia, and 1,518 m^3/sec through Jim Woodruff Lock and Dam.

Water Quality Data

Complete *in situ* and laboratory water quality results are given in Appendices C and D respectively. Water temperatures were generally highest during cycle 5 in August. The mean temperature for this cycle for Chattahoochee River stations (01,02,03,04, 05,06) was 28.2°C; for Flint River stations (16 and 17), 27.8°C; for lake stations (08,09,10,11,13,15), 29.2°C; and for stations on the

Apalachicola River, 28.8°C. Station 12, on a wide, shallow, relatively stagnant arm of the reservoir had a water temperature of 27.5°C during this cycle and station 14 on Spring Creek was 27.0°C. However, at stations 12 and 14 the water temperature was highest during cycle 4 in July being 30.0°C and 29.0°C, respectively. All of these temperatures are within 1°C of the maximum temperatures found during Phase I. Minimum temperatures were encountered during cycle 1 in February with reservoir and river stations having temperatures of 7.5°C-10.5°C. Stations 12 and 14 had temperatures of approximately 13°C at this time. However, the temperature was lowest (11.0°C) for these two stations during cycle 7 in December. At no time during this study was a well defined thermocline evident at any of the lake stations sampled due probably to the shallowness of the reservoir and wind mixing of it. However, during cycle 3 (June), cycle 4(July), and cycle 5 (August), a slight (i.e., 1-2°C) surface warming was apparent at most lake stations. The greatest vertical variation gradient was observed at station 11 during cycle 4 with a difference of 4°C between the top and the bottom (Appendix F). No significant lateral thermal variation was observed during the fourth sampling cycle in July.

In general the D.O. levels found during Phase II were very similar to those found during Phase I. No anaerobic conditions were encountered at any sampling sites during any of the sampling cycles. The most severe dissolved oxygen depletion occurred during cycles 4, 5, and 6 in July, August, and September, respectively, due probably to reduced mixing and increased temperature. Dissolved oxygen during these summer months averaged about 7 mg/l (Appendix F) and ranged from a high of 12.3 mg/l one meter below the surface at station 15 to 4.2 mg/l five meters below the surface at station 11 just upstream of the dam (see Figure 1). Vertical profiles and D.O. isopleths for cycles 3 through 7 showing the variation in D.O. with depth and cross-section, respectively, at a given site are shown in Appendix F. In general, the reservoir stations exhibited a decrease in D.O. with depth during the late summer months; however, a marked thermocline did not develop and mixing from top to bottom was not inhibited. No significant lateral or vertical variation in dissolved oxygen was evident at any of the river stations during either the February or July sampling cycles with the exception of station 14 in Spring Creek during July. The variation found at this station (Appendix C) was probably due to the lack of current and mixing. At station 1 (just below the George W. Andrews Lock and Dam) the D.O. ranged from above 9.5 in February, April and December to a low of 7.3 at midstream in July. At station 18 (just below the Jim Woodruff Lock and Dam) the D.O. ranged from above 8.5 in February, April, and December to a low of 6.6 in July and September at midstream.

pH values for all stations during all the Phase II sampling cycles ranged from 6.8 to 8.9 at one meter below the surface. This compares with 6.7 to 9.1 during Phase I. During June and August, stations 11, 13, and 15 had a vertical variation in pH of 0.5 to 0.8 units but a horizontal variation of 1.5 units measured one meter below the surface.

The reverse was true of station 15 which had only a 0.2 horizontal pH variation but a vertical variation of 0.5 to 1.4 units at the various locations sampled (Appendix F). The remainder of the lake stations had no significant variation in pH. No significant lateral or vertical variation in pH was evident at any of the river stations during either cycle 1 in February or cycle 4 in July when extensive measurements were made (Appendix C).

All oxidation-reduction potentials (O.R.P.) in this report have been referenced to the $Pt/H_2,H$ system. In general, O.R.P.'s ranged from +280 mV to +590 mV for all stations during all Phase II sampling cycles (Appendix C). This range compares favorably to Phase I levels when the range was from about +300 mV to about +600 mV for all stations during all cycles. An exception to this trend was station BO, just below the Great Southern Land and Paper Company outfall on the Chattahoochee River, Mile 38.2. Here the O.R.P. dropped sharply during cycles 1, 3, and 4 to values ranging from +6 to +170 mV. According to the values in Appendix D, the slight variation in other parameters measured at this station (water temperature, conductivity, dissolved oxygen, and pH) do not correspond or account for the changes in O.R.P. O.R.P. levels were also lower at this location during Phase I, ranging from +60 to +290 mV during cycles 2, 3, 5, and 6.

Turbidity over all the cycles during Phase II was highest for the Chattahoochee stations with a mean value of 11.1 FTU. The mean value for the Flint River stations was 6.8 FTU, the reservoir stations 10.5 FTU, and the Apalachicola stations 9.7 FTU. Turbidity at station 12 on Fish Pond Drain averaged 1.6 FTU and station 14 on Spring Creek averaged 3.7 FTU. Suspended solids concentrations, secchi disc, and percent light transmission exhibited the same general areal trends as turbidity. These same trends were also observed during Phase I.

Specific conductance, total dissolved solids (T.D.S.) and alkalinity all followed the same general areal patterns during both Phase I and II. All three parameters were lowest at the Chattahoochee River sampling sites (01-06), and generally higher on the Flint River arm of the reservoir. Station 14 on Spring Creek yielded the highest values for all three parameters for all the sampling cycles, except during cycle 3 of Phase II when alkalinity was higher in the Flint River.

Total iron concentrations were fairly high at times compared to the EPA criterion (U.S. EPA, 1976) and exhibited several areal and chronological trends. In all cases, the total iron was composed primarily of insoluble forms and followed the same trends observed during Phase I. Concentrations in the Chattahoochee were highest during cycle 2 in the spring, with values ranging from 1.2 mg/l to 3.5 mg/l. There was a general downward trend after the second cycle until cycle 6 in September when the values ranged from 0.3 mg/l to 0.6 mg/l. December showed the beginning of another upward trend. Concentrations in the Flint River were highest during the third sampling cycle with values ranging from

1.5 mg/l to 1.6 mg/l, and lowest during the fifth cycle in August with values around 0.5 mg/l. Concentrations in the reservoir were higher during cycles 1 through 3 and then dropped off during the remainder of the year except in September when they reached a mean peak of 1.3 mg/l. Spring Creek and Fish Pond Drain had much lower concentrations. In the Apalachicola River the concentrations were again highest during cycle 1 and were approximately 1.2 mg/l. The concentrations then declined to 0.7 mg/l during cycle 5 in August. It should be noted that concentrations of total iron at most of the stations during the spring and early summer months exceeded the suggested EPA criterion of 1.0 mg/l for fresh water aquatic life (U.S. EPA, 1976).

Concentrations of manganese and zinc were low at all times with concentrations never exceeding 0.2 mg/l during both Phase I and Phase II. There were no obvious areal patterns. Neither Georgia nor Alabama have numerical criteria for zinc or manganese.

Total inorganic nitrogen (TIN) concentrations were very similar during Phase II compared to Phase I and followed the same trends. Total inorganic nitrogen, composed primarily of nitrate-nitrite, was generally highest on the Flint River stations during the entire phase with values ranging from 0.49 mg/l to 0.78 mg/l. The Chattahoochee River and the reservoir stations were highest in the spring, decreased over the summer, and rose again in the fall. Mean values in the Chattahoochee ranged from a low of 0.13 mg/l in August to a high of 0.51 mg/l in February. In the Apalachicola River, values followed the same trend with a high concentration of 0.41 mg/l during cycle 1 to a low concentration of 0.12 mg/l in August. Total phosphorus values were generally much lower during Phase II than during Phase I. During Phase II, all values were between 0.01 and 0.07 mg/l. Stations in the reservoir and in the Chattahoochee and Flint Rivers showed no significant areal variation. In the Apalachicola River all values were $\leq$0.05 mg/l. Station 12 on Fish Pond Drain had extremely low values of both TIN ($\leq$0.12 mg/l) and total P ($\leq$0.002 mg/l). Station 14 on Spring Creek showed low total phosphorus ($\leq$0.03 mg/l) but high TIN (0.38-0.57 mg/l). Dissolved orthophosphate values comprised a low percentage of the total phosphorus concentration, usually less than 20 percent, except in the Flint River where it comprised 50-80 percent of the total. Total Kjeldahl nitrogen and total organic nitrogen also showed no significant areal variation during either cycles 4-6 of Phase I or cycles 1, 5, or 7 of Phase II.

Color (measured in PT-CO units) was fairly uniform throughout the reservoir and on the Apalachicola, Chattahoochee, and Flint Rivers during both Phases I and II. However, values were slightly lower in the fall (August-December cycles) and also generally lower at stations 12 and 14.

All dissolved sulfate values were less than 15 mg SO_4/l during both Phases I and II. The Flint River generally had lower levels

(mean 2.4 mg SO_4/l) than the Apalachicola River, Chattahoochee River, or the reservoir stations. In both Spring Creek (station 14) and Fish Pond Drain (station 12), all values were less than 6 mg SO_4/l and most values were less than 1 mg SO_4/l.

During Phase I and Phase II there were no distinctive trends in measured carbon dioxide levels. However, there was a tendency for CO_2 levels to be higher at all stations during the last cycle of both Phase I and Phase II. The highest values (10.8 and 13.6 mg CO_2/l) were found at staitons 16 and 17, respectively, during December, 1979.

Chloride and total potassium, sodium, calcium, hardness, and magnesium were only sampled during cycles 4 and 6 in Phase I and cycles 1, 5, and 7 in Phase II. Values for chloride ranged between 3 mg Cl/l and 7 mg Cl/l with no areal trends observed. Total potassium values were less than 2.8 mg K/l at all stations except during December, 1979, when values ranged from 1.8 (station 11) to 13.6 mg K/l (station 17). Total sodium values ranged from 1.15 to 13.4 mg Na/l. There was a slight reduction in level in the Flint River and at stations 12 and 14 compared to levels in the Apalachicola River, Chattahoochee River, and at the reservoir stations. The Chattahoochee River had lower total calcium mean concentrations than the rest of the stations. Values for all stations ranged from 2.3 to a high value of 35 mg Ca/l at station 14 in December, 1979. Total magnesium showed no distinctive trends. All values were between 0.2-7.5 mg Mg/l during both Phase I and Phase II with the low and high value occurring at stations 12 and 15, respectively, during August, 1978. Total hardness followed the same trend as calcium. The lowest values were found at the Chattahoochee River stations and the highest values at station 14 in Spring Creek.

Bacteriology

Bacteriology results for Phase II are included in Appendix D. In Phase II, samples were collected for fecal coliform and fecal streptococci during all sampling cycles except cycle 2. Samples were collected at all the water quality sampling stations plus two stations near public park facilities, B1 and B2. Due to bad media and/or equipment malfunctions, bacteriological results are incomplete for stations 07 through 11, 18 and 19 in August and stations 01 through 05, 11, and 13 through 19 in December. Station B2 was not sampled in July due to boat problems. Although a complete set of data was not obtained, enough data were obtained to establish several trends which followed the same patterns found during Phase I. Generally the Chattahoochee stations were rather low in fecal coliforms with most stations under 50/100 ml during Phase II except during cycles 1 and 5 when values ranged up to 390/100 ml. The Flint River stations were significantly higher, especially during cycle 1 of Phase II when the count reached

1405/100 ml at station 17. Coliform counts during Phase I were also significantly higher in the Flint River with the highest concentration of 2,500/100 ml at station 17 during cycle 2 of Phase I. Reservoir stations as well as Spring Creek, Fish Pond Drain and stations B1 and B2 were all low in coliforms. State standards for coliforms are 1000/100 ml in Georgia for waters classified for fishing and 200/100 ml in Florida for Class II waters. Coliform counts did exceed these standards several times throughout the study. During both Phase I and Phase II, fecal strep counts tended to be highest on the Apalachicola and Chattahoochee Rivers and low in the reservoir itself except during cycle 6 of Phase II when counts were as high as 2700/100 ml at station 10. Fish Pond Drain, Spring Creek, and the Flint River also had low values generally. Fecal coliform to fecal strep ratios as shown in Appendix D tend to indicate that human sources of contamination predominate on the Flint; and agricultural sources on the Chattahoochee and Apalachicola Rivers.

Sediments

Complete surface sediment data tabulations and gradation curves for stations 01-19 during cycle 5 are presented in Appendix L.

Physically, the surface sediments in the Chattahoochee, Flint, and Apalachicola Rivers are sands and sandy loams with the sediments at stations 18 and 19 in the Apalachicola River containing a significant gravel component. Surface sediments in the reservoir range from sand at station 13 to loam and sandy loam at stations 08, 09, 10, and 14 to silt loam at station 11. A summary of the physical characteristics as well as the USDA Textural classification of the sediments at each station is presented in Table 7.

In general, total organic carbon content and the percent loss on ignition (i.e. volatile solids) were closely related to the physical nature of the sediments. Both total organic carbon and loss on ignition were inversely related to the sand and gravel content. Those stations composed primarily of sands and gravels had TOC values ranging from 0.051 to 9.26 gm C/kg dry weight and percent loss on ignition values from 0.1 to 1.5 percent. Those stations with sediments characterized as loams had corresponding TOC values ranging from 17 to 64.6 gm C/km dry wt. and percent loss on ignition values of 6.6 to 11.3 percent. Sediment nutrient concentrations, as measured by total Kjeldahl nitrogen and total phosphorus as well as oil and grease levels were correlated to the TOC of the sediment and thus, the sediment physical characteristics. Highest nutrient levels were found at reservoir stations 08, 09, 10, 11, 13, and 15 and at station 14 in

Spring Creek during both Phase I and Phase II. For these stations during Phase II, total Kjeldahl nitrogen ranged from 337 mg/kg at station 13 to 4960 mg/kg at station 14. Total phosphorus ranged from 31.3 mg/kg at station 11 to 424 mg/kg at station 10.

Metal analyses were run on the sediments as As, Cd, Cr, Cu, Fe, Pb, Mn, Hg, Ni, and Zn. In general, sediment heavy metals concentrations were highest at reservoir stations with a higher silt and clay faction, i.e. at stations 08, 09, 10, 11, 13, and 15. Mean concentrations at these stations ranged from 1.2X (Cu) to 2.8X (As) the overall mean concentration and from 1.4X (Hg) to 27X (Cu) mean concentrations observed at the Chattahoochee and Flint River stations, i.e. stations 01, 02, 03, 04, 05, and 07 and stations 16 and 17, respectively. With the exceptions of Cr at station 14 and Hg at station 12, highest metals concentrations were observed at reservoir stations 10 (Mn), 11 (As, Cu, Fe, Pb, Ni, and Zn) and 13 (Cd). Generally, metals concentrations were lowest at stations in the Chattahoochee, Flint, and Apalachicola Rivers with sandy substrates. Average metal concentrations tended to be slightly lower in the Chattahoochee River than either the Flint or Apalachicola River. At the sites in Fish Pond Drain and Spring Creek, i.e. stations 12 and 14, respectively, concentrations of metals in the sediments exhibited no apparent pattern, with levels ranging between the extremes.

Pesticide concentrations were generally below detection limits although levels of the PCB Aroclor 1254 and the DDT metabolite p,p-DDE were detected at a number of sites. At these sites, PCB levels from 16 to 64 µg/kg were found at stations 02, 08, 09, 17, 18, and 19 with the highest level at station 19. During Phase I, detectable PCB Aroclor 1254 levels ranged from 38.7 to 753 µg/kg at stations 07, 08, 10, 12, 14, 16, and 17 with the highest level at station 14. DDE levels from 1.1 to 5.4 µg/kg were detected at stations 05, 08, 10, 13, 14, and 15 with the highest level at station 14. During Phase I, p,p-DDE was below the detection level at all stations. In contrast to Phase I when detectable levels of 2-4D were found at stations 01, 03, 06, and 09, no detectable 2-4D was found at any stations during Phase II. Due to the limited pesticide sampling, no definite trends can be ascertained.

Corbicula

Corbicula were found only at station 19 during cycle 5 of Phase II in August. Heavy metals and chlorinated hydrocarbon analyses were conducted on the sample. The results of these analyses are shown in Appendix K. Of the four heavy metals for which tissue analyses were performed, a Food and Drug Administration (FDA) Action Level has been established only for mercury. This level is 1.0 ppm for shellfish, approximately five times above the level found at station 19 during Phase II. During Phase I, all of the levels found in the samples from August were at least an order of magnitude below the FDA Action Level. During Phase I, the Corbicula sample at station 19 had 40.0 µg/kg wet wt. of chlordane and 10.0 µg/kg wet wt. of endosulfan sulfate in August.

NOTES:

1 Source: Chow, 1964
2 D_{60} = diameter at which 60% of the particles are finer than the value shown.
3 D_{10} = diameter at which 10% of the particles are finer than the value shown.
4 $U = D_{60}/D_{10}$ = uniformity coefficient.
5 Includes a significant gravel component.

During August of Phase II, both of these parameters were below the detection limit at station 19. An FDA Action Level for fish of 0.3 ppm has been established for chlordane. This level is over 7 times the highest level observed at any station during Phase I (FDA, 1979).

Algal Growth Potential

The ability of the waters of Lake Seminole to support algal growth was measured three times during Phase II of the project. Eleven stations (Table 3) were analyzed during cycle 2 (April), cycle 4 (July), and cycle 6 (September). All flask counts were completed for cycle 2. However, during cycle 4 some of the flasks were not counted at day 14 because they had either turned achlorotic or a fungus was observed to be present. In September, a procedural error was made resulting in contamination of the culture flasks with nutrients from the stock culture. The test was concluded and then rerun with the remaining water. For stations 9, 10, 11, 15, and 16 some of the EDTA spiked replicates were omitted due to insufficient sample volume remaining. Growth was also very poor in September and may have been due to a decline in the physiological condition of the test organisms. The complete data base including background water quality analyses of the nitrogen and phosphorus forms and concentrations occurring in the samples assayed for algal growth potential are shown in Appendix G. The AGP results submitted to the Environmental Protection Agency's Data Storage and Retrieval System (STORET Code 70988) consists of the mean of the average of the 12 day and 14 day growth in the unspiked water. In general the chemical analyses showed that dissolved ortho-phosphate was released from the condensed phosphate fraction during autoclaving. Total inorganic nitrogen (TIN) also increased slightly in many of the samples due to autoclaving. Most of these increases were due to ammonia released from the organic nitrogen fraction. Total Kjeldahl nitrogen and total phosphorus decreased slightly in most samples after processing except during cycle 6 when increase was noted.

In general, the condensed phosphorus and organic nitrogen fraction was not used for algal growth. Results of the replicated spiked and unspiked samples counted at 12 and at 14 days agreed within the ±20 percent precision considered acceptable for the results of this type of assay except in September. However, due to lack of sufficient sample, the test could not be repeated.

Table 8 summarizes the overall mean algal growth potential and primary limiting nutrient as determined by analysis of nitrate, orthophosphate and EDTA spikes. Except in September when it was in the moderate range, the algal biomass produced in the unspiked lake water is indicative of moderately high to high productivity as defined by Miller et al. 1974. These authors surveyed algal growth potential in 49 lakes and set up four categories of relative productivity based on algal growth potential:

Low	0 - 0.1 mg l^{-1}
Moderate	0.11 - 0.8 mg l^{-1}
Moderate High	0.8 - 6.0 mg l^{-1}
High	6.0 - 20.0 mg l^{-1}

TABLE 8

LAKE SEMINOLE WATER QUALITY MANAGEMENT STUDY
SUMMARY OF ALGAL GROWTH POTENTIAL RESULTS FOR
PHASE II (FEBRUARY, 1979 THROUGH DECEMBER, 1979)

Station Number	Algal Growth Potential ($mg\ l^{-1}$)[1] and Primary Limiting Nutrient(s) (N or P)[2] Cycle 2 April 2-4, 1979	Cycle 4 July 16-19, 1979	Cycle 6 Sept. 24-26, 1979
06	7.84(P)	8.81(P)	0.63(P)
07	6.03(P)	6.65(P)	0.22(P)
09	7.19(P)	5.17(P)	0.38(P)
10	7.37(P)	4.15(P)	0.19(P)
11	5.62(P)	3.68(P)	0.19(P)
12	(3)	1.64(N,P)	0.14(P)
13	11.4(P)	2.34(P)	0.26(P)
14	1.74(P)	1.53(P)	0.45(P)
15	9.95(P)	7.56(P)	0.39 (4)
16	10.4(P)	11.1(P)	0.56(4)
18	8.47(P)	4.20(P)	0.18(P)

NOTES:

[1]Mean of both 12 and 14 day counts with no nutrients added.

[2](N) = Limited by total inorganic nitrogen.
(P) = Limited by available phosphorus.

[3]Station not sampled.

[4]Unable to determine due to inconsistent growth.

Comparing the algal growth potential categories with trophic state as defined by other characteristics, Miller et al. 1974 found that lakes with moderately high or high algal growth potential were classed as eutrophic.

The algal growth potential in the reservoir proper (stations 09, 10, 11, 13, and 15) decreased over the course of the summer. Algal growth potential at station 18, below the dam, followed the pattern of the reservoir stations. Stations 12 and 14, located in relatively isolated areas of the reservoir showed a much lower algal growth potential than the reservoir or the river stations.

The stations located upstream in both the Flint (station 16) and Chattahoochee (stations 06 and 07) Rivers generally had higher algal growth potentials than the stations located in the main body of the reservoir. No toxic responses were evident in the algal assay data at station 16 even though other biological population measurements (phytoplankton, ATP, zooplankton) suggest that a toxic impact may limit plankton population development in the reach below Bainbridge. If a toxic factor is present at station 16 it is apparently removed by autoclaving and/or filtration.

The results of nitrate, phosphate and EDTA spiked tests show that trace metals do not limit algal growth response. Areal differentiation of the primary limiting nutrient occurred during the course of the summer during Phase I. In the spring the entire reservoir was phosphorus limited but many areas became nitrogen limited over the course of the summer months. During Phase II however, this trend was not observed and phosphorus remained the limiting nutrient throughout the year.

Phytoplankton

In general, the Lake Seminole phytoplankton counts show what one would expect (Fogg, 1975) in an impoundment system and generally showed the same trends observed during Phase I. During the February and April sampling periods, the water temperature ranged from 7.5° to 22°C. Diatoms made up the largest percentage (88 and 74 percent during February and April respectively) of the phytoplankton association with Melosira distans being the most abundant (Appendix H). Asterionella formosa, which prefers cooler water (Werner, 1977), was also found during these months (Appendix H).

As the water temperature increased during the summer to a maximum of 27 to 30°C during August, there was a shift in the algal plankton association from diatoms which prefer temperatures below 30°C to blue-green algae which can grow well above 34°C (Werner, 1977). During August, blue-green algae made up 75 percent of the plankton association (Table 9). This compares very well with the results of Phase I during which the blue-green algae made up 76 percent of the plankton association in August and September.

TABLE 9

LAKE SEMINOLE WATER QUALITY MANAGEMENT STUDY
SUMMARY OF PHYTOPLANKTON COUNTS BY MAJOR DIVISION FOR PHASE II
(FEBRUARY, 1979 THROUGH DECEMBER, 1979)

	Cycle 1 Feb. 19-22, 1979		Cycle 2 April 2-4, 1979		Cycle 3 June 4-6, 1979		Cycle 4 July 16-19, 1979		Cycle 5 Aug. 13-16, 1979		Cycle 6 Sept. 24-26, 1979		Cycle 7 Dec. 3-6, 1979

TOTALS	87,067	99	142,492	100	112,942	99	241,233	100	275,386	100	143,692	100	74,505	100

NOTES: 1. Cumulative cell density (Cells/ml) for all stations per cycle.
2. Percent of total cumulative cell density for all stations per cycle.

During both Phase I and Phase II, there were no observed algal blooms of only one or two species. The lack of a definite spring and/or fall phytoplankton bloom may have been the result of the high turbidity in the system since this is a known turbidity effect (Werner, 1977). Instead there was a gradual phytoplankton increase from an average of 4,592 cells/ml in February to 15,299 cells/ml in August (again comparing well with an average cell density of 13,540 cells/ml during August of Phase I). In general, the phytoplankton densities in the Chattahoochee River were higher than in the reservoir during February, September, and December while the reverse was true during the summer sampling periods (Table 10). As noted in the Phase I report, the phytoplankton densities were extremely low at stations 16 and particularly 17. The reason for this is still unknown. Further study upstream of station 17 to mile 37.0 in the Flint River resulted in densities comparable to those at station 17.

Of the diatom species found during both Phase I and Phase II, most were characteristic of water with a pH near 7.0 (Lowe, 1974; Patrick and Reimer, 1966, 1975). Only a few frustules of genera characteristic of low pH (acidic water) such as Eunotia, Tabellaria, and Pinnularia were found. These were probably washed into the system from a tributary or in runoff.

A complete listing of phytoplankton cell densities by taxa at each station is given in Appendix H.

Zooplankton

The results of the Lake Seminole zooplankton counts for Phase II are shown in Appendix I. These results are summarized in Table 11 by major zooplankton groups for each cycle. During Phase II, zooplankton were most abundant during cycle 7 in December with a mean station concentration of 67 organisms/l. As shown in Table 11, the population density was composed primarily of Rotifera during all cycles except 3 and 6. This compares favorably with Phase I during which Rotifera comprised 50-91 percent of the total from July through November.

At stations 16 and 17 on the Flint River there was a marked reduction in zooplankton densities (Table 12) similar to that shown for phytoplankton. Further study upstream of station 17 to mile 37.0 resulted in densities comparable to those at stations 16 and 17. The reason for these low densities is unknown. Zooplankton densities at station 14 on Spring Creek were also lower than densities found throughout the rest of the system. At the reservoir stations, zooplankton were most abundant during the summer months when phytoplankton were also abundant.

ATP Test Results

The ATP concentration from the depth integrated water sample at each station ranged from 20 ng/l to 725 ng/l during Phase II. The highest value was found at station 19 during the June sampling period.

*Arrived back at WAR lab unfrozen.
**Not sampled due to boat problems.
***Sample lost during storage.

The ATP results are shown in Table 13. During the last three months of 1979, the liquid scintillation spectrometer was nonoperational and the September and December samples were stored frozen until it was repaired. During this storage period, approximately half of the samples for these cycles were accidently discarded resulting in incomplete data in Table 12.

Comparison of phytoplankton densities (Table 10) to ATP concentrations (Table 13) at each station shows that the numbers correspond very poorly. This is because of the great difference in cell size of the organisms. A diatom such as Navicula cryptocephala may be 40 μ long and 18 μ wide in contrast to a blue-green alga such as Microcyctis incerta which has spherical 1 μ diameter cells making up each colonial unit. Therefore, one Navicula cell would contain a much greater amount of ATP than a Microcystis cell.

Since the test includes ATP from phytoplankton, zooplankton, and bacteria it is reasonable not to expect a good correlation with any one of these separately or with total chlorophyll. Taken all together however, the trend in ATP concentration tends to follow the trends for phytoplankton, zooplankton and chlorophyll. Generally during both Phase I and Phase II, the highest ATP concentrations were found in the reservoir and the Chattahoochee and Apalachicola Rivers. Moderate values were found at station 14 and the lowest values were in the Flint River and at station 12.

Macroinvertebrates

The macroinvertebrate sampling results are summarized in Appendix J. The Chattahoochee River (stations 01 through 07) supports sparse populations of a few species of benthos adapted for a shifting sand environment. These were dominated by Corbicula and turbellarians, with chironomids and oligochaetes being consistently present although in low numbers. The oligochaetes were primarily tubificids and a new species of Enchytraeidae, Barbidrilus paucisetus (Loden and Locy, In press). The Flint River stations (16 and 17) were also characterized by shifting sands, however, the species associations were different. These were dominated by Corbicula, with oligochaetes, chironomids and turbellarians as sub-dominants. The oligochaetes were primarily tubificids and naidids. Benthic macroinvertebrate populations in the Flint River did not exhibit the depressed characteristics recorded for zooplankton and phytoplankton.

The open-water, "reservoir" stations (08, 09, 10, 11, 13, and 15) have substrates composed mostly of silt, clay, and detritus. Here the dominant benthic organisms were Hexagenia, tubificids, and chironomids. Corbicula and Chaoborus were also common.

Apalachicola River stations 18 and 19 were located within a gravel bed, a substrate much more conducive to benthic productivity than the sands and silts of the other stations. Wet weight biomass values here (Table 14) were consistently 2-3 orders of magnitude higher than at all other stations. This area was dominated by Corbicula and

Potamyia flava. Chironomids, oligochaetes, and turbellarians are also very abundant.

Station 12 was located in a wide, shallow, relatively stagnant area, with a silty sediment high in detribus and dense, submerged aquatic macrophytes. Biomass here was consistently one order of magnitude higher than at the other stations in the reservoir. The dominant benthos were Corbicula, oligochaetes, and chironomids. Hexagenia was present but uncommon. It is likely that macroinvertebrates were much denser here than the benthic data indicate, as the abundant aquatic macrophytes could easily support more macroinvertebrates than the sediments.

Station 14 is similar to the reservoir stations in that it has silty sediments high in detritus and the benthos was dominated by Hexagenia, tubificids, and chironomids, with Corbicula and Chaoborus being common. The number of taxa was much higher, however, possibly due to the very dense submerged macrophytes.

Evenness and Shannon-Weaver diversity values (base 2) were computed for the benthos and are shown in Tables 15 and 16. The data from the three samples collected at each station were combined and the values computed from that. The values ranged from 0.253 to 3.517. Comparisons between stations show that the diversities for the Chattahoochee River stations were relatively low for stations 01 through 07 and ranged from 0.253 to 2.825 with an overall mean of 1.42. The highest diversity was found at station 14 (Spring Creek) and ranged from 2.071 to 3.469 with an overall mean of 2.707. The remaining stations had moderate diversities. Evenness values paralleled diversity; where diversity was relatively high, evenness was relatively high, and where diversity was low, evenness was low. "Biomass" estimates also paralleled diversity values.

Of the total 48 Hester-Dendy artificial substrate samplers placed during Phase II, 41 were recovered (see Appendix J). Similar to Phase I, all but a few supported macroinvertebrate densities of 5,000 or less per square meter. This occurred generally in the Chattahoochee River, the open reservoir, Fish Pond Drain, and Spring Creek, but also occurred in the Apalachicola River during cycles 1 and 2 in late winter and early spring. The remaining samplers retrieved from the Apalachicola River held the greatest macroinvertebrate densities for Phase II Hester-Dendy units. This data is summarized in Table 17. Numbers of taxa tended to be relatively higher during cycle 2. Overall, the greatest numbers of taxa occurred in the Chattahoochee River. Otherwise, the numbers of taxa were remarkably constant, generally being 8 to 10 at all areas for all cycles except cycle 6 in Fish Pond Drain, where a single predaceous dragonfly nymph (Libellula sp.) was found on the sampler.

Species diversity values were generally moderate to low (Table 18). The Chattahoochee River samplers supported a wide range of diversities, including most of the highest values and some of the lowest. This is probably as much an artifact of the low organism densities as it is an indication of relative environmental health. The remainder of the samplers supported a narrower range of diversities.

Chattahoochee River stations were dominated by midge (Chironomidae) larvae, primarily Glyptotendipes sp. and other filter-feeding phytoplanktivores. Mayfly (Ephemeroptera) larvae, filter-feeding caddisfly (Tricoptera) larvae, and naidid (Naididae) oligochaetes were also present but in moderate to low numbers. Flint River samplers were heavily dominated (95 percent of total number of organisms) by midge larvae, primarily Cricotopus spp. and Thienemanniella xena, which are aufwuchs feeders. Amphipods, mayfly larvae, and caddisfly larvae were also present in significant numbers.

The Apalachicola River samplers were dominated (94 percent of total number of organisms) by midge larvae (primarily Cricotopus spp.) during cycle 2 and by caddisfly larvae (77 percent) during cycles 4 and 6. The caddisfly larvae were composed almost entirely by the phytoplanktivore Potamyia flava. Triclad turbellarians (Dugesia?) formed almost 11 percent of the organisms on the cycle 6 samplers.

The open reservoir stations (9, 11, 13) sampled were dominated by phytoplanktivorous midges (Glyptotendipes sp., Dicrotendipes spp.) and a phytoplanktivorous caddisfly larva (Phylocentropus sp.). Naidid oligochaetes, which feed on aufwuchs, were common during cycle 2.

Macroinvertebrate densities were generally lowest in Fish Pond Drain (station 12) and Spring Creek (station 14), probably because of the paucity of algal food (phytoplankton and aufwuchs). Station 12 was dominated during cycle 4 by Hyalella azteca, an amphipod, and by the midge Endochironomus sp. Station 14 was dominated during cycle 2 by Hyalella azetca, naidid oligochaetes, and the mayfly Stenonema sp.; and during cycle 6 by Dicrotendipes spp., Glyptotendipes sp., and Phylocentropus sp.

Macrophytes

Aquatic macrophytes are probably the most conspicuous feature of Lake Seminole. Reservoir personnel have identified over 700 taxa of macrophytes from aquatic situations. Approximately 73 taxa were recorded in this survey to be common to abundant (Appendix M). They cover an estimated 40.1 percent of the area of the reservoir (Table 19). They have become a severe nuisance in many locations such as access channels and boat ramps. The distribution of aquatic macrophytes in

*Surface area of the total reservoir assumed to be 37,500 acres (USACOE.n.d.).

Lake Seminole is shown in Figure 4 and categorized by species association in Table 19.

Submersed vegetation occurs almost everywhere the water is transparent enough to allow sunlight to penetrate to the bottom. Emergent vegetation occurs almost everywhere the water is shallow enough for them to become established. Where the water is too turbid or too deep, floating plants have the potential to become very dense. Intensive spraying of herbicides during 1978 and 1979 kept the floating plants to a minimum. However, in the Flint River where hyacinths were reduced by herbicide spraying, broken patches of floating algal mats were present over large areas. Spraying has also been conducted over the last few years in a number of small access channels and canals. In every instance, though, aquatic macrophytes were quickly reestablished, and by the middle of the following growing season the macrophytes were once again of nuisance proportions. For this reason, and due to the very high costs, spraying has been conducted generally only on selected areas of high cultural use such as boat ramps and access channels. The morphometry of the reservoir and the relatively high nutrient inputs virtually assure that aquatic macrophytes will be a major management problem for the remainder of the reservoir's life.

SUMMARY

The purpose of Phase I and II of the Lake Seminole Water Quality Management Study was the establishment of a comprehensive water quality, sediment, and biological data base at various sites within the impoundment, in the backwater stretches of the major tributaries, and immediately downstream of the outfall on the Apalachicola River. This data base is to be utilized for the combined purposes of future reference, guidance in the improvement of reservoir operations, facilitation of coordination with state agencies in the implementation of watershed pollution control measures, and identification of significant water quality problems.

Meteorological, hydrological, water quality, sediment, and biological data were obtained at a total of 19 main sampling stations in Lake Seminole, the Chattahoochee River, the Flint River, Spring Creek, Fish Pond Drain, and the Apalachicola River during 6 sampling cycles in Phase I (April through November, 1978) and 7 sampling cycles during Phase II (February through December, 1979). Limited sampling and analyses were also performed at 5 special sampling sites at various times during the course of this study. Biological sampling included bacteria, phytoplankton, zooplankton, macroinvertebrates, and aquatic plants.

Average monthly flows through the impoundment during Phase II ranged from 349 m^3/sec. during August to 1518 m^3/sec. during April. These values compare to a low of 221 m^3/sec. during November and a high of 1005 m^3/sec. during May of Phase I. During the study period, the Chattahoochee River accounted for 50-80 percent of the flow into the impoundment. As a result of operational procedures at the Walter F. George Lock and Dam on the Chattahoochee River upstream of Lake Seminole, flows through the Chattahoochee River impoundment arm exhibited considerable short term variation.

In general, each of the major impoundment arms of Lake Seminole tended to be well-mixed both laterally and vertically. Little lateral variation and essentially no vertical stratification was observed in temperature, dissolved oxygen, pH, or oxidation-reduction potentials during the April, 1978; August, 1978; February, 1979; or August, 1979 sampling cycles during which extensive in situ sampling was performed. Although surface warming at most lake stations was evident during the summer (June, July, and August), the shallowness of the impoundment prevented the development of a well-defined thermocline.

Average turbidity levels in the Chattahoochee River were approximately two to three times those in the Flint River with suspended solids, Secchi disk, and percent light transmittance exhibiting the same general areal pattern over the course of the study. Specific conductance, total dissolved solids, and alkalinity were lowest at the Chattahoochee River

sites and generally higher on the Flint River during both years of the study. The Chattahoochee River also had lower mean levels of total calcium and total hardness than the rest of the stations. Concentrations of most of the other inorganic water quality parameters, except nutrients, showed no significant areal or chronological patterns. Concentrations of all sampled metals, except iron, were generally low with no obvious areal patterns. Concentrations of total iron at most stations during the spring and early summer months exceeded the EPA criterion of 1.0 mg/l for freshwater aquatic life. In all cases, total iron was composed primarily of insoluble forms.

Total inorganic nitrogen ranged from 0.30 to 0.78 mg/l at Flint River stations to 0.08 to 0.53 mg/l at Chattahoochee River stations. Levels were generally highest in the spring, decreased over the summer, and rose again in the fall. Total phosphorus values were generally much lower during Phase II than during Phase I. During Phase II, all values were between 0.01 and 0.07 mg/l. Dissolved orthophosphate values comprised usually less than 20% of the total phosphate except in the Flint River where it comprised the majority of it.

In general, based on nutrient content, the waters of Lake Seminole tended to be moderate to highly productive with respect to the production of algal biomass. On the basis of potential algal production alone, the system would be classed as eutrophic. During the spring of Phase I, the system was phosphorus limited, with many areas becoming nitrogen limited as the summer progressed. During Phase II however, this trend was not observed and phosphorus remained the limiting nutrient throughout the year. Trace metals did not appear to limit algal growth and no toxicity effects were observed at station 16 near Bainbridge.

Phytoplankton populations were characteristic of a system of this type with no observed algal blooms of one or two species. The lack of a spring and/or fall phytoplankton bloom may have been the result of the high turbidity in the system although a slight peak was observed during April of Phase II. Lowest densities were found during the winter and early spring months after which they increased to an average of approximatly 14,000 cells/ml in August. As the temperatures increased during the spring and summer, there was a corresponding shift in the plankton associations from diatoms to blue-green algae. Phytoplankton densities were generally higher in the Chattahoochee River than in the reservoir during early spring and late fall while the reverse was true during the summer sampling periods.

During both Phase I and Phase II, phytoplankton densities were extremely low at stations 16 and 17 on the Flint River during all sampling cycles. Further study upstream of station 17 to mile 37.0 on the Flint River shows comparably low densities. It is still presently unknown if this is a toxic response or if these low densities are simply normal for the Flint River.

During both phases of this study, zooplankton assemblages exhibited little variation in the number of taxa found at each station during the year. However, zooplankton densities were greatest during September of Phase I (overall mean of 96 organisms/l) and December of Phase II (overall mean of 67 organisms/l). The Rotifera were the most abundant organisms at each station during most of the sampling cycles.

At stations 16 and 17 on the Flint River there was a marked reduction in zooplankton densities similar to that shown for phytoplankton. Generally, station 17 had fewer organisms than station 16. Further study upstream of station 17 to mile 37.0 resulted in densities comparable to those at stations 16 and 17. The reason for these low densities is unknown. Zooplankton densities at station 14 on Spring Creek were also lower than throughout the rest of the system. Reservoir station densities were highest during the summer months when phytoplankton were also abundant.

The bacteriological quality in Lake Seminole during Phases I and II ranged from good in the upper Chattahoochee River stations and at the lake stations where fecal coliform levels were generally below 100/100 ml, to poor at station 17 in the Flint River in the vicinity of Bainbridge where fecal coliform concentrations in excess of 2,500/100 ml were observed during June of Phase I and above 1,400/100 ml during February of Phase II. The fecal coliform to fecal streptococci ratios tend to indicate that human sources of contamination predominated in the Flint River and agricultural sources predominated in the Chattahoochee and Apalachicola Rivers.

ATP concentrations tended to follow the same general trends as phytoplankton, zooplankton, and chlorophyll. However, due in part to differences in total biomass, only a poor correlation existed between individual assemblages. The highest concentration (725 µg/l) was found during June of 1979 at station 19. The reason for the high value at this station is unknown. During both Phase I and Phase II the highest concentrations were generally found in the reservoir and the Chattahoochee and Apalachicola Rivers. Moderate values were found at station 14 and the lowest values were in the Flint River and at station 12.

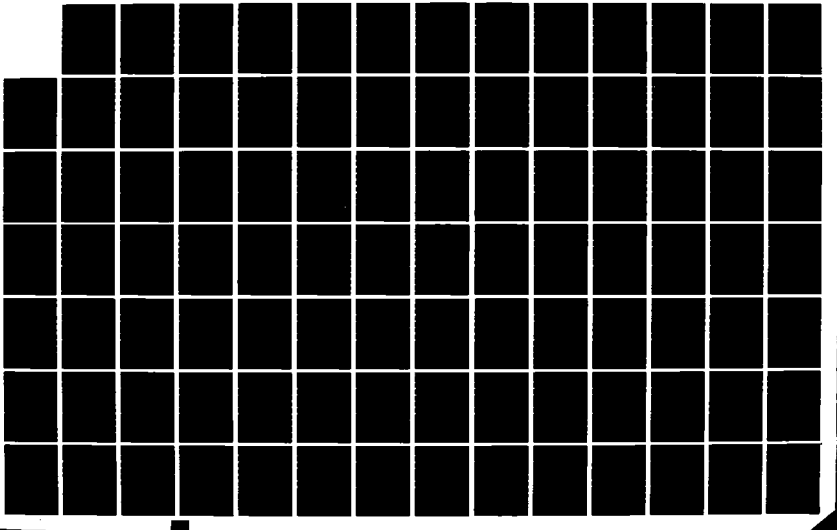

Bottom sediments ranged from relatively clean sands in the Chattahoochee, Flint, and Apalachicola Rivers to sand and sandy loams in the impoundment itself. The organic and nutrient contents tended to be related to the percent fines. Heavy metals concentrations were generally low. The concentration of most of the pesticides analyzed were below detectable limits, although levels of PCB Aroclor 1254 and p,p-DDE were detected at a number of sites with the highest PCB level (64 µg/kg) at station 19 and the highest DDE level (5.4 µg/kg) found at station 14 during Phase II. Although no detectable levels of 2-4D were found during Phase II, levels as high as 569 µg/kg (station 03) were found during Phase I.

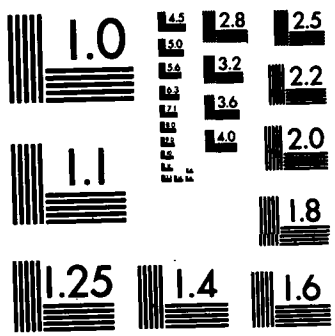

Benthic macroinvertebrate populations tended to be closely associated with the nature of the supporting substrate. Chattahoochee and Flint River stations exhibited sparse populations adapted to a shifting sand environment, although the species associations were dissimilar. Lake stations supported populations adapted to a substrate composed of finer sands, silts, and clays. The sampling sites in the Apalachicola River were characterized by a coarser, more productive substrate. Benthic diversities ranged from relatively low in the Chattahoochee River to moderate in the Flint and Apalachicola Rivers with the diversities in the reservoir varying seasonally from moderate to low, with lowest diversities occurring towards late summer. Evenness and biomass tended to closely parallel diversity. Corbicula were collected during August of both Phase I and II. However, they were found in sufficient quantity for complete analyses at only two stations during Phase I and at one station during Phase II. In all samples, the levels of mercury and chlordane (the only analyzed chemicals for which FDA Action Levels have been established) were below the FDA Action Levels.

Aquatic macrophytes constituted the most conspicuous feature of Lake Seminole. They were a severe nuisance in a number of locations such as access channels and boat ramps. Emergent and/or floating macrophytes covered over 40 percent of the total reservoir surface area and nearly 100 percent of the surface area with a depth less than 2 meters. Approximately 73 taxa were identified during this study as being either common or abundant.

RECOMMENDATIONS FOR FUTURE STUDIES

The following are areas which deserve consideration for future studies.

1. Macrophytes

Aquatic macrophytes are well established on over 40 percent of Lake Seminole, and cover almost 100 percent of the portion that is less than two meters deep. Since the macrophytes are not limited by nutrients or grazing, it is likely that they will continue to increase in extent until blocked by riverine currents or water too turbid to transmit sunlight. Even then, expansion may continue although at a reduced rate, since siltation continues to slowly fill the reservoir. Also, aquatic vegetation increases the rate of siltation (and organic matter deposition), thus increasing the rate of macrophyte expansion. Through this process, aquatic macrophytes may eventually cover the entire lentic portion of the reservoir.

This situation is a result of several factors: (1) The reservoir is generally very shallow, and in most places the water is sufficiently transparent to allow insolation to penetrate to the bottom of the water column. (2) The availability of nutrients to macrophytes from upstream sources is essentially unlimited. (3) The number of macrophyte species is so diverse, that even if a "perfect" herbicide could be developed to completely eliminate a species from the reservoir, there are dozens of species that would be able to quickly invade and repopulate the area. This is readily borne out by the experiences of reservoir personnel (D. Vickers, pers. comm.), where choked access channels were sprayed one year for Species A, and the following year they were choked with Species B.

Past management practices have been limited to small areas of high user demand due to the high economic costs. In 1978, for example, about 1,080 acres were sprayed or chopped for an estimated total cost of $76,095 (see Table 20). In 1979 and 1980, a total of 1,430 acres were treated for a cost of $213,190, an average cost of $149 per acre. Reservoir personnel had requested more than twice that amount in order to spray 5,050 acres ($100 per acre). Reservoir personnel are now asking for $300,000 to treat 2,000 acres ($150 per acre) in 1981. By way of reference, the total reservoir surface area is estimated to be 37,500. Should the whole of the infested portion of Lake Seminole be treated at an average cost of $150 per acre, the total cost would be approximately $2,250,000.

Clearly, these expensive measures can provide only temporary relief from the symptoms of greater problems. It is quite possible that a more lasting and less expensive solution(s) exists. Water

TABLE 20

LAKE SEMINOLE WATER QUALITY MANAGEMENT STUDY
SUMMARY OF COSTS INCURRED AND ACREAGES TREATED FOR AQUATIC MACROPHYTE CONTROL, 1978 TO 1981

Year	Treated[1] Acreage	$	Treatment Proposed Acreage	$
1978	1,080	76,095	NA[4]	NA
1979	50	206,070[1]	2,000	195,700
1980	1,380	7,120[3]	3,050	309,525
1981	--	--	2,000	300,000

[1]Treatment includes herbicide sprays, herbicide pellets, and mechanical chopping.

[2]These funds were spent on herbicides at the end of 1979; the acreage was subsequently treated in 1980.

[3]Airplane rental only.

[4]Not Available.

level drawdowns, for instance, have proven very beneficial in various lakes in Florida. The Lake Seminole Reservoir is a far more complex system physically than the average lake, however. A combination of several kinds of treatments may be necessary in this shallow, nutrient-rich and most botanically diverse reservoir.

2. Intensive Study of Flint River

Analysis of the data, throughout Phase I and Phase II, identified a marked reduction in phytoplankton, zooplankton, chlorophyll, and ATP levels in the Flint River at miles 24 and 29 (stations 16 and 17, respectively) near Bainbridge, Georgia. It would appear that the river is continuously stressed from a source upstream from station 17 unless the Flint River naturally has low plankton densities. Since station 17 represents the northern extremity of the present study, the limits of these conditions were not defined. The cause of this stress is unknown, but it does not appear to be physical in nature -- no gradients were observed with temperature, dissolved oxygen, conductivity, or pH from stations 15 through 17. Further study upstream of station 17 to mile 37.0 on the Flint River during the December 1979 sampling cycle resulted in plankton densities comparable to those at station 17. Further study should be conducted to determine the cause, extent, and magnitude of this possible environmental impact, which is identified by the plankton density decreases.

PARTICIPATING STAFF

A project team of engineers, biologists, chemists, and technicians conducted the study. The overall project manager was Dr. J.H. Sullivan, Jr., with the assistance of Mr. B. Bailey, Mr. R. Blum, and Mr. J. Nichols in logistics, data analysis, and field activities. Dr. H. D. Putnam served as coordinator and advisor for the biological activities. Mr. M. Hein and Mr. B. Pruitt were responsible for the field and in-house biological efforts with the assistance of Ms. P. Dickinson and Charles Markum.

Mr. B. Bailey and Mr. M. Hein were responsible for the coordination of field water quality sampling and reporting. Analytical procedures were supervised by Ms. C. Hackett, Dr. M. Keirn, and Ms. M. Schultz with the assistance of Mr. G. Burch, Mr. S. Hall, Mr. L. Larson, Ms. M. Neves, Mr. P. Nathanson, and Mr. M. Timpe. Dr. M. Keirn and Mr. M. Hein coordinated the Algal Growth Potential test work. Mr. J. Nichols supervised and coordinated all the computerized data handling with the assistance of Mr. M. Timpe and Ms. K. Barnes. Field personnel included Mr. B. Bailey, Mr. R. Blum, Mr. S. Chamberlin, Mr. M. Hein, Mr. B. Pruitt, Mr. M. Putnam, and Mr. M. Timpe.

The final copy was produced by Ms. J. Dorsey, Ms. D. Nickelson, Ms. J. Nyland, Ms. C. Hoffenberg, and Ms. P. Paschall.

ACKNOWLEDGEMENTS

We would like to thank Angus Gholson and his colleagues at the Jim Woodruff Project Offices for their generous help throughout this study, including Joseph Kyte, Jerry Shelby, Howard Sellers, and Holmes Walters. We would like to pay special tribute to Donald Vickers, deceased during the course of this study, for giving freely of his patience, kindness, and knowledge during the macrophyte surveys.

APPENDIX M

AQUATIC MACROPHYTES

LIST OF TABLES

TABLE	DESCRIPTION	PAGE NO.
M-1	Aquatic Macrophytes Noted to be Common To Abundant in Lake Seminole During the 1978 & 1979 Field Surveys	M-1
M-2	Approximate Percent Cover of the Dominant Aquatic Macrophytes Observed in Various Areas of Lake Seminole 1978 & 1979	M-3

TABLE M-1

AQUATIC MACROPHYTES NOTED TO BE COMMON TO ABUNDANT
IN LAKE SEMINOLE DURING THE 1978 & 1979 FIELD SURVEYS

Algae	S*	E	F
Chara spp.; chara	x		
Lyngbya/Spirogyra; algal mat			x
Nitella spp.; nitella	x		
Vascular			
Justicia americana; water willow		x	
Sagittaria latifolia; common arrowhead		x	
Alternanthera philoxeroides; alligator-weed		x	
Colocasia esculenta; wild taro		x	
Orontium aquaticum; goldenclub		x	
Alnus serrulata; speckled alder		x	
Betula nigra; river birch		x	
Brasenia schreberi; watershield		x	
Cabomba caroliniana; fanwort	x		
Sphenclea zeylandica; chicken spike		x	
Ceratophyllum demersum; common coontail	x		
Ceratophyllum echinatum; prickly coontail	x		
Mikania scandens; climbing hempweed		x	
Carex spp.; sedges		x	
Cyperus spp.; sedges		x	
Eleocharis acicularis; slender spikerush		x	
Eleocharis cellulosa; spikerush		x	
Eleocharis equisetodes; knotted spikerush		x	
Hydrochloa carolinensis; water grass		x	
Leersia hexandra; cutgrass		x	
Panicum hemitomum; maidencane		x	
Panicum repens; torpedograss		x	
Zizaniopsis miliaceae; giant cutgrass		x	
Hypericum spp.; St. Johns wort		x	
Myriophyllum brasiliense; parrotfeather	x		
Myriophyllum spicatum; Eurasian watermilfoil	x		
Egeria densa; elodea	x		
Hydrilla verticillata; hydrilla	x		
Vallisneria americana; eelgrass	x		
Juncus effusus; soft rush		x	
Juncus spp.; rushes		x	
Lemna perpusilla; common duckweed			x
Spirodela polyrhiza; giant duckweed			x

TABLE M-1 (continued)

	S	E	F
Utricularia floridana; giant bladderwort	x		
Utricularia inflata; purple bladderwort	x		
Utricularia purpurea; floating bladderwort	x		
Mayaca fluviatilis; bog moss	x		
Nymphoides aquaticum; banana lily		x	
Myrica cerifera; wax myrtle		x	
Najas guadalupensis; southern naiad	x		
Najas minor; naiad	x		
Nelumbo lutea; American lotus		x	
Nuphar advena; spatterdock		x	
Nymphaea odorata; fragrant waterlily		x	
Nyssa aquatica; swamp tupelo		x	
Nyssa ogeche; ogeche tupelo		x	
Ludwigia decurrens; singed waterprimrose		x	
Ludwigia leptocarpa; waterprimrose		x	
Ludwigia palustris; water purslane		x	
Ludwigia peruviana; waterprimrose		x	
Platanus occidentalis; sycamore		x	
Polygonum spp.; smartweeds		x	
Eichorrnia crassipes; water hyacinth			x
Pontederia cordata; pickerelweed		x	
Pontederia lanceolata; southern pickerelweed		x	
Potamogeton diversifolius; snailseed pondweed		x	
Potamogeton illinoiensis; Illinois pondweed	x		
Potamogeton nodosus; American pondweed		x	
Cephalanthus occidentalis; buttonbush		x	
Salix caroliniana; coastal plain willow		x	
Salix nigra; black willow		x	
Saururus cernuus; lizard's tail		x	
Bacopa caroliniana; water mint	x		
Sparganium americanum; burreed		x	
Taxodium ascendens; pond cypress		x	
Taxodium distichum; bald cypress		x	
Typha domingensis; southern cattail		x	
Typha latifolia; cattail		x	
Hydrocotyle ranunculoides; splitleaf pennywort			x
Xyris spp.; yellow-eyed grass		x	

* S = Submersed
E = Emergent
F = Floating

TABLE M-2

APPROXIMATE PERCENT COVER OF THE DOMINANT AQUATIC MACROPHYTES OBSERVED IN THE VARIOUS AREAS OF LAKE SEMINOLE 1978 & 1979

	S*	E	F
Chattahoochee River Area			
Egeria densa; egeria or elodea	P		
Zizaniopsis miliaceae; giant cutgrass		90	
Justicia americana; water willow		P	
Colocasia esculenta; wild taro		P	
Sphenoclea zeylandica; chicken spike		5	
Eichornia crassipes; water hyacinth			P
Game Management Area			
Myriophyllum spicatum; Eurasian watermilfoil	75		
Myriophyllum brasiliensis; parrotfeather	5		
Cabomba caroliniana; fanwort	5		
Potamogeton illinoiense; Illinois pondweed	5		
Najas minor; naiad	5		
Najas quadalupensis; southern naiad	5		
Hydrilla verticillata; hydrilla	P		
Utricularia spp.; bladderworts	P		
Ceratophyllum demersum; common coontail	P		
Bacopa caroliniana; water mint	P		
Nymphaea odorata; fragrant water lily		5	
Brasenia schreiberi; water shield		5	
Polygonum spp.; smartweeds		P	
Pontedaria cordata; pickerelweed		P	
Panicum repens; torpedograss		5	
Panicum hemitomum; maidencane		5	
Leersia hexandra; cutgrass		5	
Eleocharis spp.; spikerushes		P	
Zizaniopsis miliaceae; giant cutgrass		10	
Eichornia crassipes; water hyacinth			P
Hydrocotyle ranunculoides; splitleaf pennywort			P
Lemna perpusilla; common duckweed			P
Fish Pond Drain Area			
Hydrilla verticillata; Hydrilla	75		
Cabomba caroliniana; fanwort	P		
Najas spp; naiads	5		
Potamogeton illinoiense; Illinois pondweed	5		
Nitella sp.; nitella	P		
Panicum repens; torpedograss	P		

TABLE M-2 (continued)

	S	E	F
Panicum hemitomum; maidencane	P
