## ABSTRACT

CP/M-86 is a single user microcomputer operating system, developed by Digital Research. This thesis provides a multi-user protected CP/M-86 based disk sharing environment consisting of four Intel iSBC 86/12A single board computers, a MBB-80 bubble memory, and the REMEX Data Warehouse 3200 memory storage unit. The REMEX houses a 14 inch Winchester hard disk and two flexible floppy disk drives providing in excess of 20 megabytes of data storage capacity. The major objective in the design of this system was to create a table-driven CP/M-86 Basic Input/Output System that could be quickly and easily reconfigured to adapt to any new hardware configuration. Once the system was operational, the REMEX hard disk could then serve as a "signal processor" emulation for the AEGIS system. By making direct calls to the appropriate read/write routines, stored "radar data" could be retrieved from the hard disk for use by the other system processes.

# I. INTRODUCTION

## A. BACKGROUND

One of the most popular operating systems available for microcomputers today is the family of Digital Research's CP/M operating systems. They are single user systems which can be configured to interface with nearly any existing piece of hardware simply by redesigning the Basic Input/Output System (BIOS) module of CP/M. Since CP/M is a single user system, protection from other users is not normally an issue of concern with this operating system.

MP/M, also marketed by Digital Research, is a multi-user operating system which supports multiprogramming on a uniprocessor. It is basically an expanded version of CP/M. However, MP/M provides virtually no protection for user files and very little protection for memory in the event that another user's process crashes. Furthermore, when more than one user is operating under MP/M, system response time is noticeably increased.

## B. PURPOSE

This thesis presents an implementation of CP/M-86 which will permit multiple users, each with his own microcomputer, to access the same peripheral devices in a manner similar to that of the MP/M operating system, but

with increased user protection. The peripherals used in this implementation are a 32K common memory board, a MBB-80 magnetic bubble memory configured as a floppy disk drive, and a Remex Data Warehouse memory storage unit consisting of a Winchester hard disk and two flexible floppy disk drives. In addition, computer performance is not compromised since each user has a dedicated INTEL 86/12A iSBC on which to operate.

The standard version of CP/M-86 requires that only the BIOS be altered to add additional hardware. While this is an excellent method to interface hardware with CP/M, it requires that the BIOS be rewritten every time the hardware configuration is changed. This process can become time consuming and is definitely prone to errors, thus discouraging frequent system reconfiguration. Therefore, in the design of this system, a major goal was to develop a BIOS which could easily be modified if it was necessary to convert from one hardware configuration to another.

This thesis was based on work accomplished in two previous theses. Michael Candelor's thesis entitled "Alteration of the CP/M Operating System" [Ref. 1] initially modified CP/M-86 to interface with the Intel i201 and i202 Floppy Disk Controllers. Michael Hicklin and Jeffery Neufeld, in their thesis "Adaptation of the Magnetic Bubble Memory in a Standard Microcomputer Environment", [Ref. 2] interfaced the MBB-80 Bubbl-Board and the i202

Floppy Disk Controller with the CP/M-86 Operating System. Although Hicklin and Neufeld claimed that their BIOS was table-driven, it was Nick Hammond who really identified that the BIOS functions could be truly table-driven [Ref. 3]. This thesis builds on the ideas contained in each of these previous works and expands upon them to create a more practical and versatile operating system which provides increased protection of the user's address space and files.

Once the system was operational, the REMEX hard disk could then be used to emulate the "signal processor" functions of the AEGIS system. Direct calls can be made to the appropriate read/write driver routines to retrieve stored "radar data" from the hard disk for use by the other emulated processes in the system.

This thesis has been organized into four major sections. The first section deals with an overview of CP/M-86 and the necessary steps required to create a new CP/M-86 system. It also describes how the BIOS interfaces with the other modules of CP/M-86 and the peripheral devices. Included in this section is a description of how the BIOS can be reconfigured into a table-driven operating system which will permit easy alterations to the BIOS if the hardware configuration should be modified.

The second section describes the hardware configuration utilized in this thesis. The memory organization of the MBB-80 Bubbl-Board is discussed and the design decisions

that were made to make the bubble memory compatible with the CP/M operating sytem are treated in some detail. The basic functions of the REMEX Data Warehouse are also described, as well as, the command packet structure and execution.

The third section is concerned with the development of a CP/M-86 operating system which will permit four single board computers to operate simultaneously while sharing the same peripherals. In this design, it is necessary to provide protection to common memory during read and write operations and to insure that each user's files are write protected with respect to all other uses.

The final section describes the tests that were conducted to evaluate system performance. In addition, the feasibility of using the REMEX hard disk to emulate the "signal processor" of the AEGIS system was explored. Measurements were made using direct calls to low-level read routines to determine the optimum skew factor for consecutive sector access operations. Also, some recommendations were made for future projects involving the REMEX Data Warehouse and the multi-user CP/M-86 operating system.

# II. CP/M-86

## A. THE CP/M OPERATING SYSTEM

CP/M-86 is an operating system developed for use on a single INTEL Corporation 86/12A microcomputer. CP/M is supplied with a number of built-in utility commands as well as transient utilities such as the assembler (ASM86.CMD) and the Dynamic Machine Language Program Debugger (DDT86.CMD). These are described in detail in Digital Research publications. [Refs. 4 - 6]

The CP/M operating system itself is modularized to permit easy adaption of CP/M to any hardware configuration. The three modules are the Console Command Processor (CCP), the Basic Disk Operating System (BDOS) and the user configurable Basic Input/Output System (BIOS). The first two modules are supplied by Digital Research as a single hex file entitled CPM.H86. This file contains all the code necessary for processing commands entered at the console and for handling all logical file and disk management functions. The source code for a skeleton BIOS is also provided which the user can alter to suit his individual hardware requirements. Once the BIOS has been modified, it is assembled and then concatenated with CPM.H86. The resulting hex file, CPMSYS.H86, is converted to an executable file by the use of the CP/M utility program

1. USER BIOS.A86 ==> ASM86.CMD ==> USER BIOS.H86

2. CPM.H86 + USER BIOS.H86 ==> PIP.CMD ==> CPMSYS.H86

3. CPMSYS.H86 ==> GENCMD.CMD ==> CPMSYS.CMD
(8080 CODE[A40])

4. CPMSYS.CMD ==> PIP.CMD ==> CPM.SYS
(rename on new disk)

Figure 2.1
Steps for Creating CPM.SYS

GENCMD.CMD. Finally, this file is renamed CPM.SYS and placed on a diskette for use. This process is shown in Figure 2.1. Details concerning the operation of GENCMD.CMD, LDCOPY.CMD and PIP.CMD can be found in the "CP/M-86 Operating System Guide". [Ref. 6]

CP/M-86 supports programs written in three memory models: the 8080 Model, the Small Model, and the Compact Model. All three memory models are described in detail in Reference 5. The model used in this thesis is the 8080 Model because it supports programs which have code and data areas intermixed and which normally have single segments of 64K bytes or less.

## B. LOADING CP/M-86

The file CPM.SYS is too large to fit onto the first two tracks of a normally-formatted diskette. Thus, a boot loader must be placed on these tracks and loaded into memory by the cold start loader. This boot loader program will

then bring the main CP/M operating system into memory and pass control to it.

The loader program is distributed by Digital Research in three separate modules and is basically a subset of the entire CP/M system. The modules are the Loader Console Command Processor (LDCCP.H86), the Loader Disk Operating System (LDBDOS.H86), and a user configurable Loader Basic Input/Output System (LDBIOS.A86) which is almost identical to the system BIOS. The primary differences deal with the physical memory location of the loader, the interrupt structure and the BIOS offset address within the CP/M system. Assembly of the loader BIOS is controlled by a conditional assembly switch provided in the skeleton BIOS, which is listed in Appendix E of Reference 6. The steps needed to obtain a loader BIOS are essentially the same as for creating the CPM.SYS. The exact steps are shown in Figure 2.2.

1. USER LDBIOS.A86 ==> ASM86.CMD ==> USER LDBIOS.H86
2. LDCCP.H86 + LDBDOS.H86 + USER LDBIOS.H86 ==> PIP.CMD
   ==> LOADER.H86
3. LOADER.H86 ==> GENCMD.CMD ==> LOADER.CMD
   (8080 CODE[A400])
4. LOADER.CMD ==> LDCOPY.CMD ==> LOADER.CMD
   (load on tracks 0 and 1)

Figure 2.2
Steps For Creating Boot LOADER.CMD

## C. BOOTSTRAPPING THE iSBC 86/12A

From the monitor of the iSBC 86/12A, the CP/M system loader program located on tracks Ø and 1 of the disk, can be accessed via the bootstrap or cold start loader program. This program is located in ROM or EPROM on the iSBC 86/12A board itself. Thus, for each separate device from which the system is to be booted, a new cold start loader program must be written and then burned into ROM. Finally, this ROM must be mounted on the iSBC 86/12A board where it can be accessed by the monitor program.

Currently, two cold start loader programs are available for the iSBC 86/12A. One allows the system to be booted from either the single or double density Intel MDS floppy disk drive system by executing the command GFFD4:Ø from the iSBC 86/12A 957 monitor program. When this command is executed, the program in the ROM will go out to tracks Ø and 1 of the floppy diskette and attempt to bring into memory the CP/M system loader program. Once loaded into memory, the cold start loader will then transfer control to the loader which in turn will locate the CP/M system (CPM.SYS) on the disk and load it into memory. Finally, the system loader will relinquish control to the CP/M operating system. The source code for this bootstrap program is listed in Appendix C of Reference 1.

The second program allows bootloading from the MBB-8Ø bubble memory device by issuing the command GFFD4:4.

Currently this last command can only be used when operating on the iSBC 86/12A which is labeled #1, as it is the only computer with an EPROM that contains the cold start loader for the bubble memory. The source code for this program, which was developed by Hicklin and Neufeld, can be found in Appendix D of Reference 2.

This thesis uses the bubble memory to initially boot the system. Therefore, a new cold start loader program or CP/M system loader program did not have to be developed. All that is required to change the operating system that will be loaded is to place a new CP/M system (CPM.SYS) on the bubble memory storage device.

The loader program placed on tracks 0 and 1 of the bubble memory used for loading the CP/M operating system is entitled MB80LDR.CMD. This file is created by following the steps indicated in Figure 2.2 utilizing MB80BIOS.A86 as the source file with the loader conditional assembly switch set to true.

## D. DISK PARAMETER TABLE

The CP/M-86 operating system as marketed by Digital Research is considered a table driven system since all characteristics for each I/O device is placed in a table called the Disk Parameter Table which can handle up to sixteen separate devices. This table defines the logical organization of the physical storage media for the BDOS file management functions and must be included in every BIOS.

A disk definition statement is required for each physical device and consists of a sequence of words which define the characteristics of a device. Figure 2.3 shows the format of a disk definition statement. These statements are then used to generate the Disk Parameter Table by executing the utility program entitled GENDEF.CMD [Ref 6, p.72]. The file created by this program must be included in

```
DISK DEF: dn, fsc, lsc, [skf], bls, dir, cks, ofs, [0]

        where
         dn is the logical disk number (0 to 15)
         fsc is the first physical sector number (0 or 1)
         lsc is the last logical 128 byte sector number
         skf is the optional skew factor
         bls is the data allocation block size
         dsk is the disk size in bls units
         dir is the number of directory entries
         cks is the number of "checked" directory entries
         ofs is the track offset to logical track 0
           (normally 2 as track 0 and 1 contain the loader)
         [0] is the optional 1.4 version compatibility flag
```

Figure 2.3
Format of Disk Definition statement

the BIOS using an "include" statement. The file which contains the disk definition statements for this thesis is labeled CPMMAST.DEF and used to generate a Disk Parameter Table which is located in the file called CPMMAST.LIB. These two files can be found in Appendices G and H.

To create a disk definition statement for the table, the characteristics for the device must be known. This information is usually located in the technical manuals for

the given device. For example, the disk definition statement used for the REMEX Winchester hard disk was:

```
DISKDEF 3,1,156,0,16384,255,128,0,1.
```

The first "3" indicates that the hard disk is CP/M's logical drive number "3" and can be accessed via the "D:" command from within CP/M.

The next two numbers correspond to the first and last logical sector numbers for the Winchester hard disk as seen by CP/M. The actual physical sectors for the hard disk are numbered from 1 to 39, each containing 512 bytes. Since CP/M requires the number of logical 128 byte sectors, 39 is multiplied by 4 to produce 156 logical sectors of 128 bytes. The actual mapping from the logical to the physical sectors is accomplished in the blocking and deblocking subroutines located in the code for the REMEX hard disk (RXHARD.A86) and is described in more detail in the Chapter IV.

The REMEX technical manual does not indicate what the most effective skew factor is, thus zero was chosen because it was required by the blocking and deblocking routines. However, an optimal skew factor may be determined experimentally when the REMEX hard disk is used to emulate the "signal processor" of the AEGIS system. If so, the blocking/deblocking routine will have to be modified at that time.

The "bls" parameter specifies the number of bytes allocated to each data block. This number can be 1024, 2048, 4096, 8192, or 16,384. When larger block sizes are used, each directory entry can address more data. This reduces the amount of work that the BIOS must do, resulting in reduced system response time. Therefore, a block size of 16,384 was chosen.

The "dsk" specifies the total disk size in terms of data blocks. It is derived by dividing the total byte capacity of the disk by the data block size. In this implementation, the Winchester disk contains approximately 20 megabytes of data storage which is subdivided between four separate heads. Thus 4,193,280 bytes are allocated to the "D:" drive and this figure is divided by 16,384 to produce 255 data blocks.

The next figure, 128, indicates the number of directory entries that are permitted on this drive.

The "cks" term determines the number of directory items to be checked on each directory scan and is primarily used for detecting changed disks during system operations. As the Winchester disk is permanently mounted, a value of zero was chosen for this parameter.

The "ofs" value determines the number of tracks to be skipped when accessing the disk. In essence, it reserves tracks for permanent storage. Track 0 is reserved since the Remex requires it for internal system use and errors will

occur if an attempt is made to access it. On a floppy disk, this value is usually two as tracks 0 and 1 are normally reserved for the loader program.

## E. THE STANDARD BIOS

The BIOS for CP/M-86 always begins at an offset of 2500 hex from the beginning of the CP/M-86 operating system. At this location are twenty-one entry points used by the CCP and the BDOS to gain access to the BIOS functions. These entry points form a jump vector to other subroutines in the BIOS which contain the necessary code to interface with each hardware device.

There are three types of functions in the BIOS: system initialization/reinitalization, simple character I/O and disk I/O. Several of these functions are normally not implemented in most microcomputer systems, while others require extensive and quite different code implementations for each separate device. The BIOS also contains the Disk Parameter Tables which represent the physical description of the disk drives. Finally, located at the end of the BIOS, there is a scratchpad area for certain BDOS operations. Figure 2.4 shows the memory map of the BIOS.

In order to simply access a diskette, several functions located within the BIOS may have to be performed. For example, to access the directory of a diskette, the BDOS will require the following functions to be performed by the BIOS: SELDSK, HOME, SETTRK, SETSEC, SETDMA, SETDMAB and

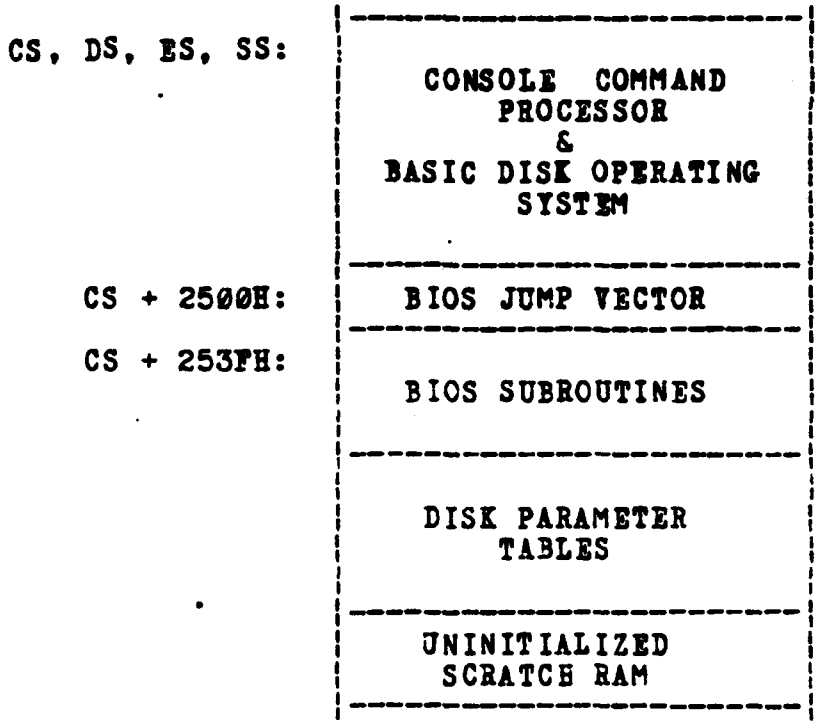

Figure 2.4
Memory Map of the Standard BIOS

READ. [Ref. 6: p.60] For each function executed, the BIOS will have to determine which physical device is being accessed and then jump to or call the subroutine which contains the code for that specific device. For example, suppose a simple READ function is required by the BDOS. It will initiate a call to the BIOS READ entry point which in turn will vector the call to the READ subroutine. Here the BIOS will determine which physical device corresponds to the CP/M's logical drive and then jump to the appropriate code to read data from that specific device. (See Figure 2.5)

This procedure is very logical and makes it easy for a user to implement his specific device dependent

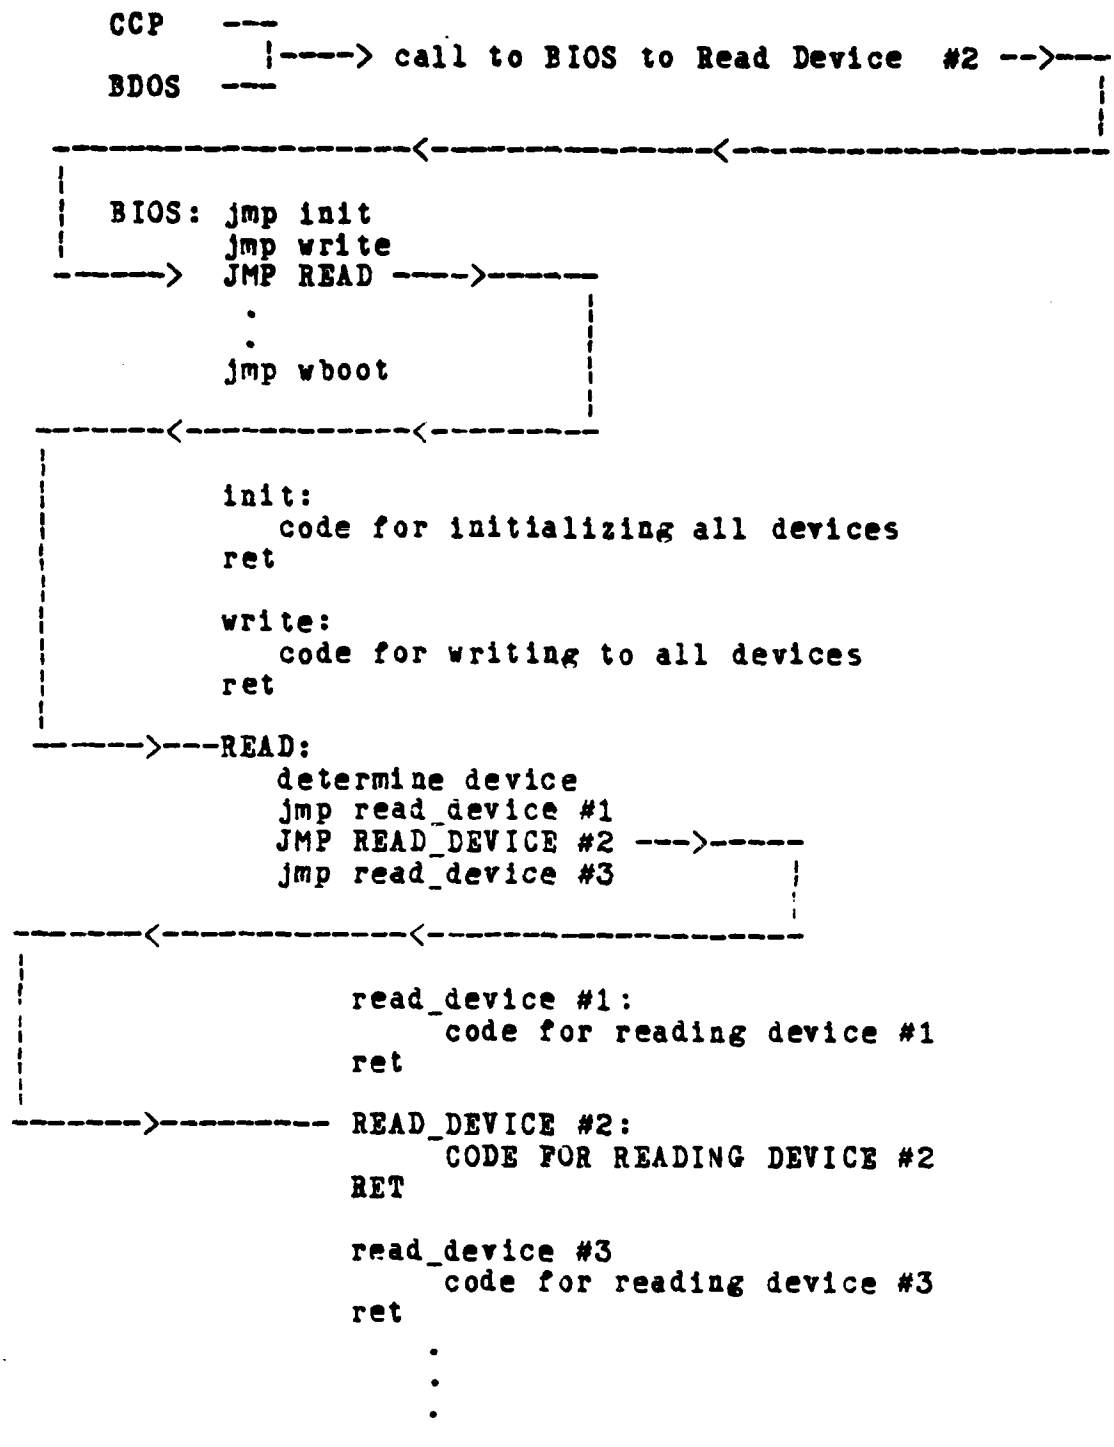

Figure 2.5
Path of CCP or BDOS Function
Call in the Standard BIOS

code. However, problems arise if the hardware configuration must be altered. Everytime the configuration changes, the code for each function in the BIOS must be rewritten. This can be a time consuming task. In addition, assumptions made concerning the implementation of one configuration may lead to errors in another configuration should those assumptions no longer be valid. These errors may also be extremely difficult to locate and correct since all code is usually intermixed and the exact order that the CCP and BDOS call various functions in the BIOS is not known to the user.

## F. BIOS ALTERATION

Hicklin and Neufeld attempted to develop a table driven BIOS. In a manner of speaking they succeeded. However, the only devices that are permitted in their device table are additional Intel MDS double density disk drive systems and MBB-80 bubble memory storage devices. Attempting to integrate another device such as the REMEX Data Warehouse, leads to the same problems which were mentioned earlier.

To alleviate these problems, a completely table-driven BIOS was developed in which only minor and straight-forward changes would have to be made in order to change hardware configurations. This was accomplished by extracting out all the device-dependent functions of the BIOS into separate files for each unique device. Specifically, these functions were INIT, SELDSK, HOME, SELTRK, SELSEC, READ, and WRITE. Functions such as WBOOT are not dependent upon a particular

device and do not have to be extracted, while functions such as PUNCH and READER are not implemented.

In the hardware configuration for this thesis, three separate files were required. These were MB80DSK.A86, RXFLOP.A86, RXHARD.A86. These files each contain the necessary code to execute the seven device-specific functions for the MBB-80 bubble storage device, the Remex

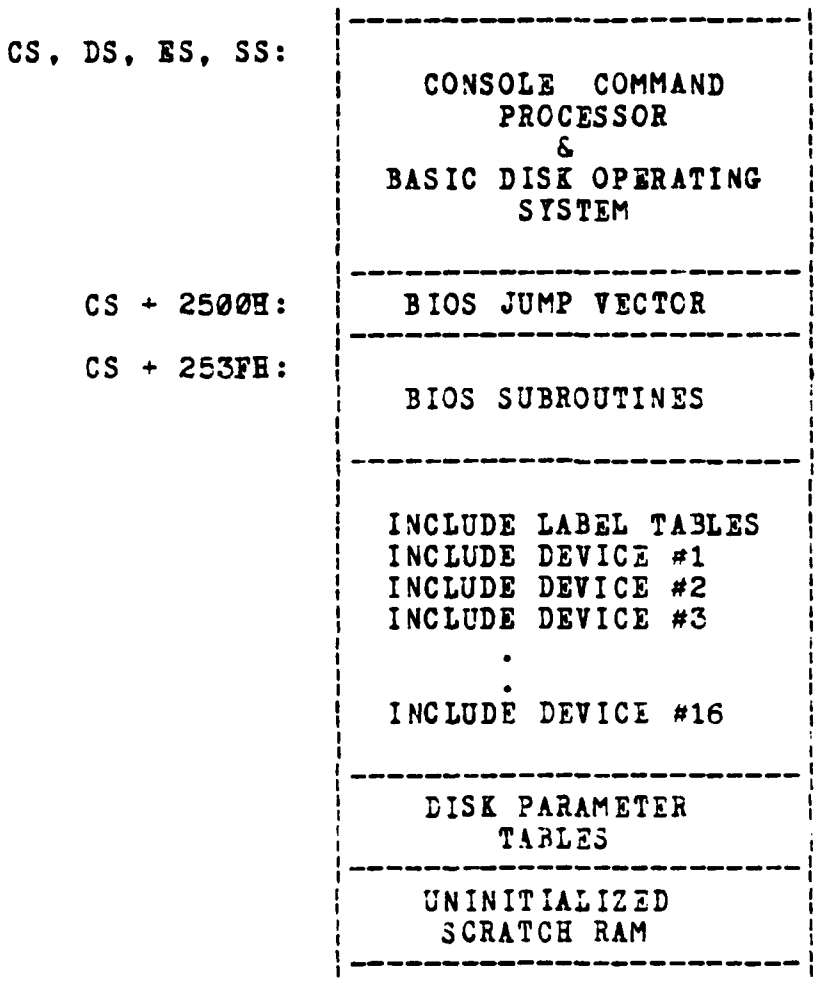

Figure 2.6
Memory Map of the Table-Driven BIOS

floppy disk drives, and the Remex hard disk, respectively. An additional file, CPMMAST.CFG, is also now required. It contains tables of labels which correspond to the physical memory location of the seven functions for each device used in a given hardware configuration. The label tables used in this thesis can be found in Appendix C. Figure 2.6 shows the memory map of the table driven BIOS. In the BIOS, the assembly language instruction "include" is used to incorporate the label tables and device-specific code for the seven functions into the system.

For example, when a call is made to read Device #2 from the CCP or the BDOS, the call is vectored as was done before through the jump vector to the READ subroutine of the BIOS. However, after determining the physical device to be accessed, instead of jumping directly to the desired code, a call is now made to the device specific code located in the included device's A86 file via the Read Table which is located in the file CPMMAST.CFG. The final address of the call is determined by the offset of device number into the Read-Table, which provides the label or 16-bit address of the actual code needed for reading Device #2. (See Figure 2.7)

To alter the hardware configuration, only one line in the BIOS must now be changed for each device, that being the corresponding "include" statement. The other changes which are required, are located in the label tables and the Disk

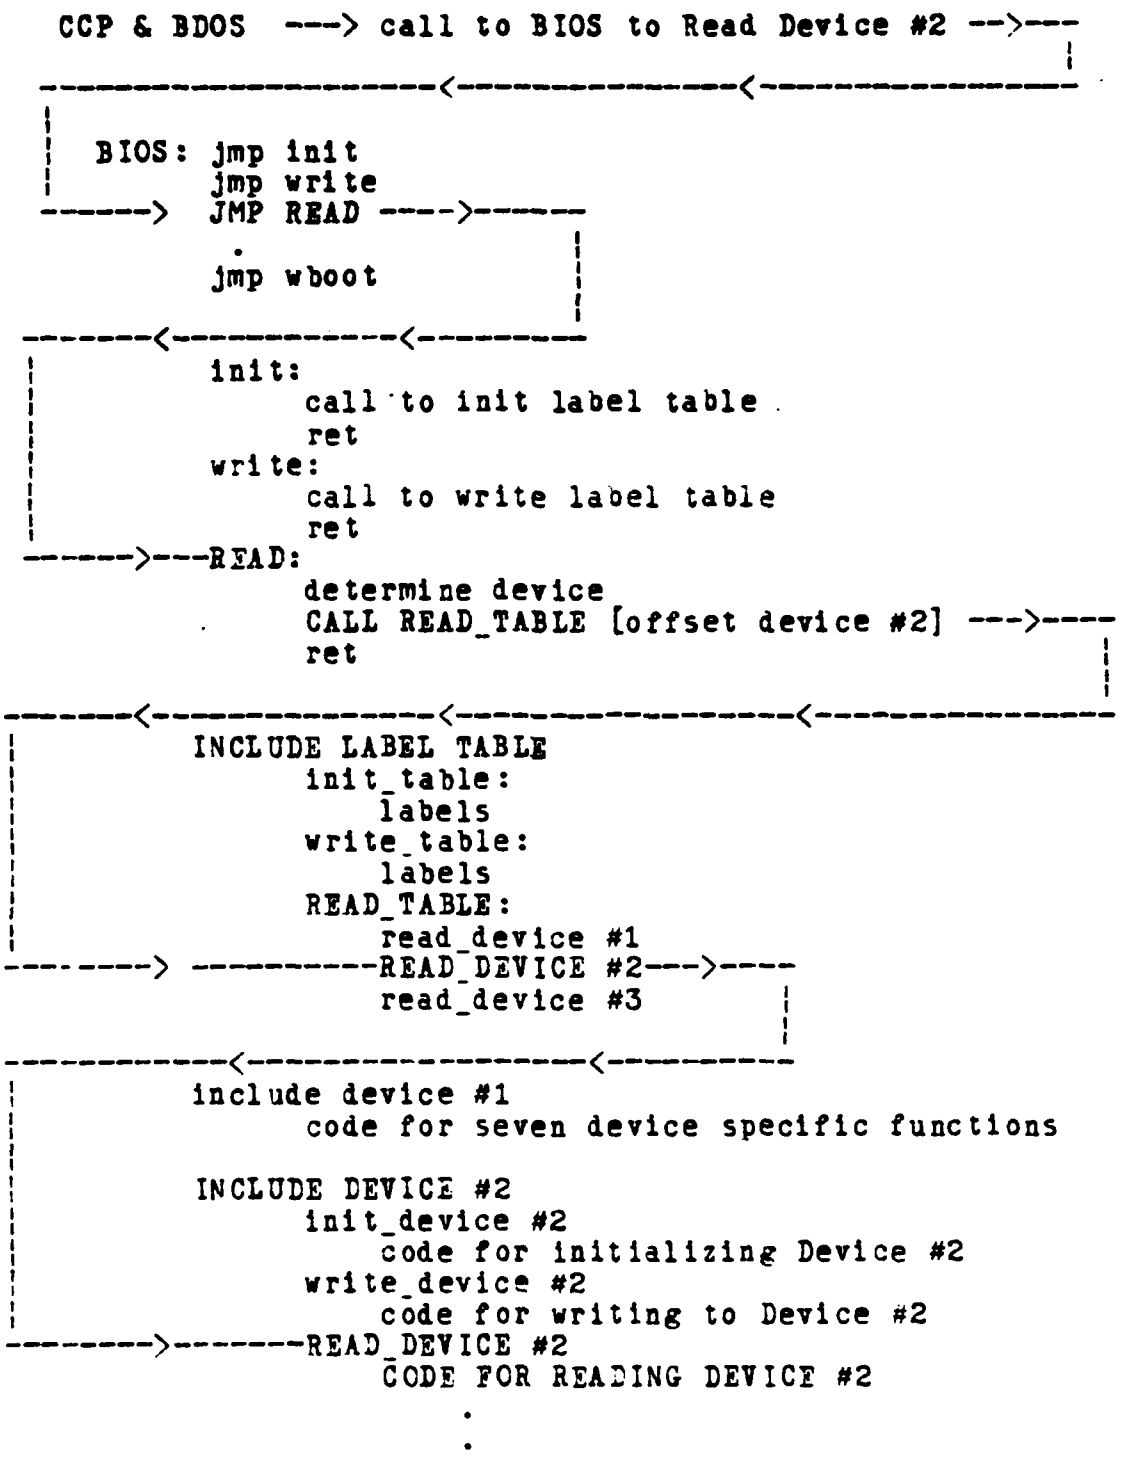

Figure 2.7
Path of CCP or BDOS Function
Call in Table-Driven BICS

Parameter Tables. For each device included in the BIOS, there must be a corresponding label for an abstracted function. These labels must be correctly ordered and properly identified. Naturally, when hardware is implemented into the system for the first time, the initial code for performing the seven device-specific functions must be written. But once written, the new device can be added or deleted from the operating system with very little effort. The fact that all code for each device is completely independent of other devices, aids in detecting, locating and correcting errors. Actual experience has shown that once the code for a device has been written, going from one hardware configuration to another can be accomplished in under twenty minutes.

# III. HARDWARE

## A. GENERAL HARDWARE CONFIGURATION

The hardware configuration utilized in this thesis consists of four iSBC 86/12A Single Board Computers, a MBB-80 Bubbl-Board, a 32K byte common memory board, and the REMEX Data Warehouse memory storage device with Multibus Interface Card Assembly. The components are all Multibus compatible and were placed in an iCS-80 Industrial Chassis for system operation. Figure 3.1 depicts the physical hardware configuration. Table 3.1 describes the logical-to-physical mapping between the CP/M representation of the system and the actual physical hardware.

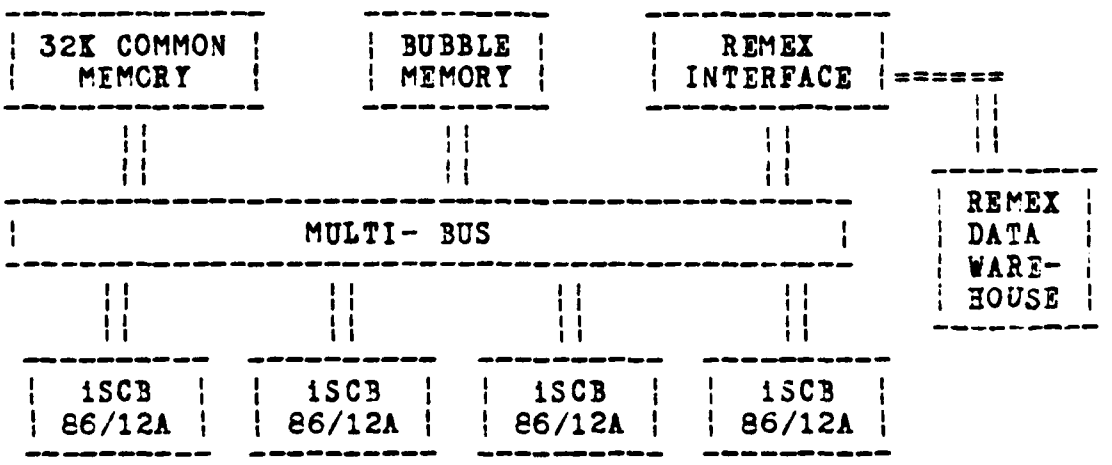

Figure 3.1
Physical Hardware Configuration

Table 3.1
Logical Hardware Configuration

| CP/M's Logical Device Number | Actual Drive | Actual Physical Device |
|---|---|---|
| 0 | A: | MBB-80 Bubble Memory |
| 1 | B: | Remex Floppy Disk Drive |
| 2 | C: | Remex Floppy Disk Drive |
| 3 | D: | Remex Hard Disk Head 0 |
| 4 | E: | Remex Hard Disk Head 1 |
| 5 | F: | Remex Hard Disk Head 2 |
| 6 | G: | Remex Hard Disk Head 3 |

B. INTEL 86/12A SINGLE BOARD COMPUTER

The Intel iSBC 86/12A Single Board Computer is a complete computer system constructed entirely on a single Multibus-compatible circuit board. It is designed to operate as a standalone system, a bus master in a single bus master system, or a bus master in a multiple bus master system. The board itself contains an Intel 8086 16-bit microprocessor, 64K bytes of dynamic RAM memory, 16K bytes of EPROM memory, both serial and parallel I/O ports, a programmable timer and interrupt controller, and a Multibus interface controller.

Onboard RAM memory is located between 0 and 0ffffh and the EPROM between FFC00h and FFFFFh within the 1-Megabyte address space available to the Intel 8086 microprocessor.

If the local processor attempts to address memory outside of these ranges, a Multibus access will result. The onboard RAM is dual-ported, and therefore is accessible to the local processor via an internal bus, as well as, to any external Multibus master via the Multibus. In this latter case, the onboard RAM is operating in the RAM-Slave mode. Any collisions that result when the RAM is simultaneously accessed by the local CPU and the Multibus are resolved by hardware in favor of the local CPU.

While the location of RAM relative to the local processor is fixed between 0 and FFFFh, it can be switch-and- jumper configured into any 128K segment of the 1-Megabyte address space relative to the Multibus. In addition, none or all of the onboard RAM, in segments of 16K, may be reserved strictly for local CPU use. Since the major objective of this implementation was to produce a CP/M-based multicomputer system in which each computer operates totally independently of the others, each iSBC 86/12A was configured to make all of the onboard RAM inaccesible to the Multibus.

## C. MBB-80 BUBBLE MEMORY STORAGE DEVICE

### 1. General Description

The MBB-80 Bubbl-Board is a complete bubble memory storage device designed to be compatible with all 8- and 16-bit microcomputers that utilize Intel's Multibus architecture. The board consists of eight (8) TIB0203

bubble devices and the necessary control, buffering, and Multibus interface logic. The host CPU interfaces with the MBB-80 controller via memory-mapped I/O utilizing any sixteen (16) consecutive user-defined addresses within the 1-Megabyte system address space. These sixteen (16) addresses correspond to the sixteen (16) registers in the bubble memory controller that are utilized in support of the following controller primitive commands:

| | |
|---|---|
| Fill Buffer | Read Multiple Pages |
| Empty Buffer | Initialize |
| Write Single Page | Read Status |
| Read Single Page | Enable/Disable Interupts |
| Write Multiple Pages | Reset |

2. Read/Write Logic

Read and write operations with the MBB-80 are accomplished by specifying a particular bubble device number and page number (18 bytes) to read from or write to. The MBB-80 controller provides the ability to read or write in either a single- or multiple-page mode by using a byte-by-byte transfer into a FIFO buffer located on the MBB-80 board itself. The single-page mode can be implemented in a straight-foward manner without the need for addtional supporting hardware or software. However, the multiple-page mode requires that certain timing requirements must be adhered to by the host CPU when communicating with the MBB-80 controller. During a data transfer, the host must

respond to interrupts generated by the MBB-80 every 160 microseconds which signal the completed transfer of one byte of information in a multi-byte transfer. These interrupts can be generated on the Multibus and handled by the Programmable Interupt Controller (PIC), or the host CPU can poll the controller interrupt register (offset 0fh) to determine if an interrupt has occurred. The single- and multi-page polled modes were implemented by Hicklin and Neufeld [Ref. 2]. The final version of their system utilized the multi-page polled mode and this was subsequently employed in this implementation.

3. CP/M-86 Compatibility

In order to effect a data transfer, the MBB-80 controller must be given a device and initial page number to locate the position where the data will be read from or written to. On the other hand, CP/M uses a track and sector number to access data during a disk access. Therefore, a mapping must be made from the CP/M track and sector number to MBB-80 device and page numbers if the CP/M operating system is going to be used to access data on the MBB-80 Bubbl-Board. Hicklin and Neufeld [Ref. 2] decided to use the bubble page number as the smallest addressable unit for each data transfer and the basis for the MBB-80 memory organization. Since each physical bubble page is eighteen (18) bytes long, a logical CP/M sector of 128 bytes consists of eight (8) bubble pages of which the last sixteen (16)

bytes on the last page are not used (i.e. wasted). Therefore, the 640 bubble pages per device are mapped into 80 logical CP/M sectors per device. Futhermore, it was decided that each MBB-80 "track" would consist of 26 sectors which corresponds to the number of sectors per track on a normally-formatted single-density floppy disk. Another design decision was that all MBB-80 tracks would be completely contained on a single bubble device. Since there are 26 CP/M sectors per track and 80 sectors per bubble device, this results in three (3) tracks per bubble device with two (2) sectors not used or wasted on each device. Therefore, based on these design decisions, the total capacity of the MBB-80 Bubbl-Board is 78K bytes on 24 tracks (8 devices x 3 tracks per device) with a total of 14K bytes wasted. Hicklin and Neufeld's final memory organization for the MBB-80 is shown in Figure 3.2. Dispite its inefficiency, this configuration was adopted for this implementation since the principal function of the bubble memory is to provide a convenient method of booting CP/M-86 on our master iSBC 86/12A. Hammond [Ref. 3] has shown that there is a more efficient way to organize the MBB-80 in his work on utilizing the MBB-80 as a snared resource in a multi-microcomputer system. However, this would have necessitated the design and implementation of a new bootstrap loader program to be placed in the iSBC 86/12A

EPROM and was not judged to be of significant importance for this implementation.

MBB-80 Logical Storage Organization

## D. REMEX DATA WAREHOUSE

### 1. General Description

The REMEX Data Warehouse is a mass storage memory unit containing a fixed Winchester disk drive, two (2) flexible diskette drives (single- or double-sided), and a microprocessor controller that services all drives. The memory capacity of the fixed disk is approximately 20 megabytes and the flexible diskettes can be formatted to contain up to two (2) megabytes of storage. IBM standard FM encoding is used for the single density floppy diskette while MFM encoding is utilized for the double density diskette and the hard disk.

The fixed disk is a 14 inch enclosed disk utilizing Winchester technology and is composed of two recording surfaces. Each surface has two (2) recording heads which can each access a total of 213 tracks. Each track can contain up to 24K bytes of information. However, only 210 tracks can be referenced for normal read/write operations. The hard disk sector size is switch-selectable to either 128, 256, 512, or 1024 bytes per sector. The total storage capacity for the various sector sizes is shown in Table 3.2. In addition, the floppy diskette controllers are also switch-selectable to handle either single or double density diskettes. It is extremely important that these switch settings correspond exactly to the actual format of the hard

Table 3.2
REMEX Hard Disk Sector Selections

| Sector Size | Sectors/Track | Capacity |
|---|---|---|
| 128 | 104 | 10.7M bytes |
| 256 | 67 | 14.4M bytes |
| 512 | 39 | 16.8M bytes |
| 1024 | 21 | 18.1M bytes |

disk and diskette for the read/write operations to function correctly.

The REMEX Data Warehouse (RDW) is designed to transfer all data and command structures to and from the host computer via direct memory access (DMA). To initiate a RDW operation, the host computer builds a command packet within its local memory. This packet contains all the information necessary to effect an RDW operation. The host then sends the address of the command packet to the RDW via an interface board utilizing programmed I/O. When the RDW is ready to accept packets, it inputs the command packet via DMA, performs the required function, and transfers any data via DMA. When the function is complete, the RDW indicates this by noting it in the command packet status word or by generating an interrupt on the Multibus. Packets can be queued in the RDW up to a maximum of eight.

Some other important features of the RDW include:

-- Dynamic data buffering (2K x 16 bit buffer)

allows a continuous transfer under varying CPU conditions.

-- Dynamic buffer protects against data overrun and underrun preventing loss of data without host computer intervention.

-- Allows data transfers in large blocks of up to 64K words with a single command. Heads are automatically advanced as necessary.

-- Automatically seeks to track(s) required in command packet.

-- Permits chaining packets together in noncontinuous memory.

-- Ability to format entire disk with a single command.

--Automatic verification and assignment of alternate tracks to cover bad tracks.

2. Command Packet Organization

The basic structure of the command packet is shown in Figure 3.3. Word 0 is composed of a modifiers section, a function code block , and a logical unit section. The function code block specifies which of the six (6) particular REMEX functions is to be performed. These functions are Read, Write, Write ID and Record, Copy, Format, and Maintenance.

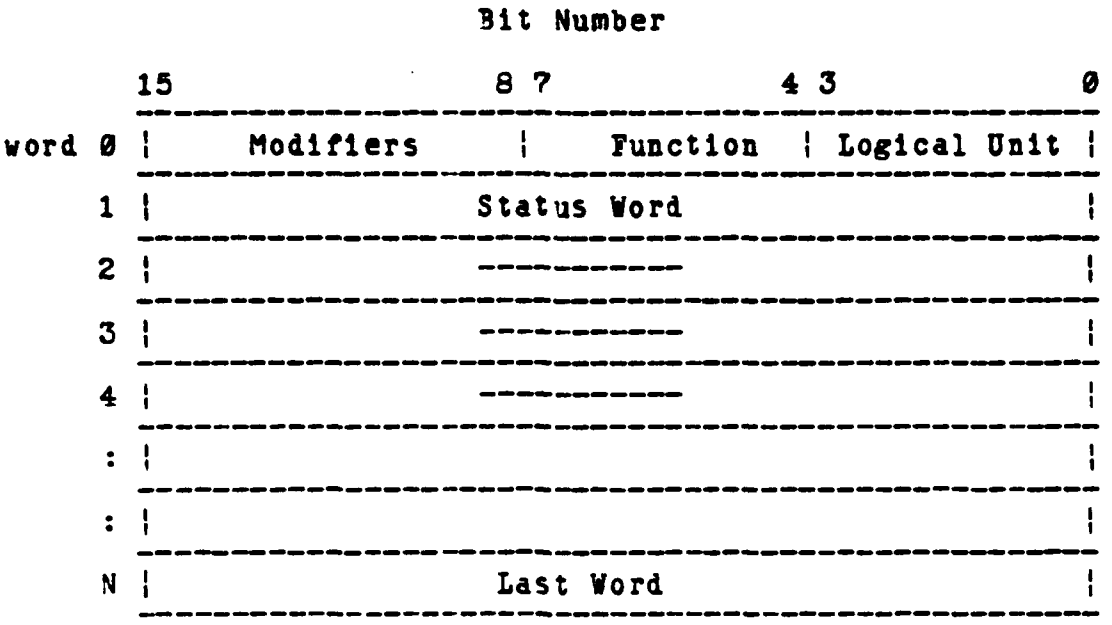

Figure 3.3
Command Packet Description

A program in the RDW interprets the function number and determines how many words are required for each specific command packet. The modifiers section contains information on packet chaining, program control interrupts, disabling of error routines and an "end" marker which specifies a single packet or the last packet in a packet string. The logical unit can be either 0, 1, or 2. A zero always corresponds to the hard disk. However, the floppy diskette drive can be operator-configured to respond to either logical unit number 1 or 2. This is accomplished by the Device Logical Unit Switch located on the front panel of the RDW.

The status word is divided into the least significant bits (0-7) and the most significant bits (8-15). Each of the least significant bits, when set to (1),

Table 3.3
REMEX Error Codes

| Bit No. | Description |
|---|---|
| 0 | Normal Completion |
| 1 | Not Assigned |
| 2 | Controller Error |
| 3 | Drive Error |
| 4 | CRC Error |
| 5 | Illegal Packet |
| 6 | Bad Track During Format |
| 7 | Not Assigned |

represents a particular status which is indicated in Table 3.3 Bits 8- 15 represent the hex code that corresponds to the error definitions given in Table 3-6 of Reference 7.

Words 2 through N are function dependent and the number of words per command packet varies widely between RDW operations. In the version of CP/M developed in this thesis, only the Read/Write function are implemented and are used to access and transfer data. However, additional utility programs were written which utilize the other functions to format the hard disk (RXFORMAT.CMD) and to execute the built-in maintenance programs (RXMAINT.CMD) of the RDW.

The format of the Read/Write packet is shown in Figure 3.4. The description of these two operations is identical except that in a read operation a one (1) is

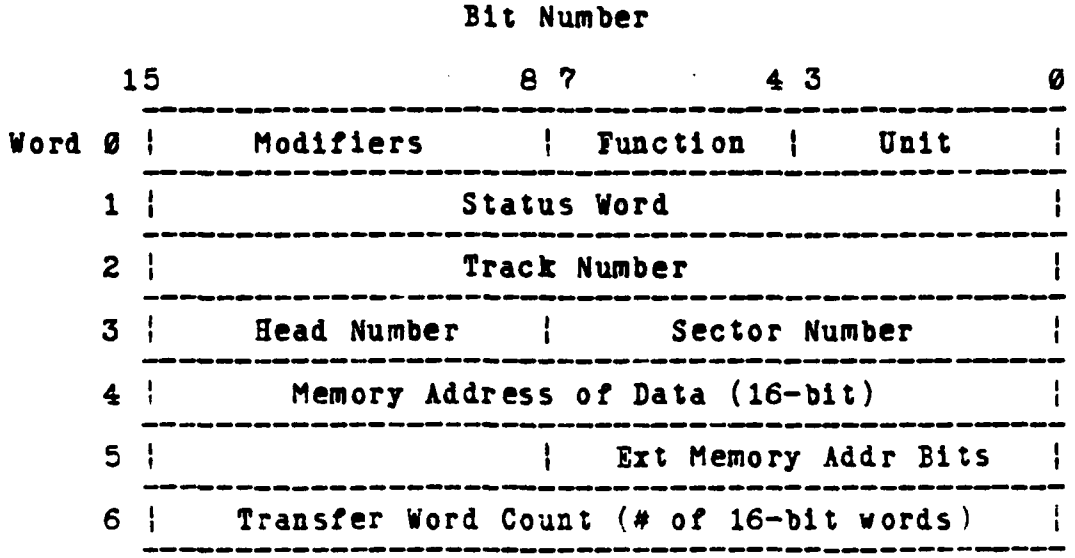

Figure 3.4
REMEX Read/Write Packet

placed in the function code block of packet word Ø and for a write operation a two (2) is used. Both operations are permitted in blocks of up to 64K words. Any head switching or advancing which may be required is automatically performed by the RDW disk controller.

RDW track numbers are assigned from 1 to 210 for normal data transfer operations. Track Ø is always reserved for a loader or system program and can not be addressed during a normal read or write operation without generating an error. Presently, the hard disk is formatted for 512 bytes per sector which corresponds to 39 sectors per track. Head numbers for the four RDW heads run from Ø through 3. Data addresses are a 24-bit representation of the 20-bit address structure supported by the iSBC 86/12A and Multibus architecture. The transfer word count is the number of 16-

bit words that are to be transferred. For accessing the hard disk, a transfer word count of 100h was placed in the packet built by CP/M. This figure corresponds to a single sector (512 bytes) or 256 16-bit words on the hard disk, which is equivalent to the CP/M-86 Operating System view of 512 8-bit words.

3. Multibus Interface Card Assembly

The command packets are sent to the RDW via a Multibus Interface Card Assembly. The interface contains all the necessary buffers, registers and control logic required for the transfer of data, status, addresses and commands between the REMEX Data Warehouse and the iSBC 86/12A Single Board Computer. The interface operates in both a programmed I/O mode and a DMA mode. All data, status, and commands are transferred by DMA, while packet addresses and the interface Command/Status information are transferred via programmed I/O. During these transfers, the Multibus Interface acts as a bus master in the DMA mode and as a bus slave in the programmed I/O mode [Ref. 8]. Registers are provided for data, packet address holding, and DMA addresses. A DMA address counter (20 bits) allows memory addressing of up to 1-Megabyte. Control logic for DMA, bus timing, interrupt control and device address selection is also provided. Selection switches are available to alter the interface base address, interrupt priority level, and the

DMA throttle which governs how long the interface must wait between DMA transfers.

In the programmed I/O mode of operation, the Multibus Inteface responds only to I/O port addresses. Switches, as mentioned above, are used to set the base interface port address. The standard addresses for the Command/Status Register are port address 070 (least significant byte) and port address 071 (most significant byte). The standard addresses for the Packet/DMA Register are port addreses 072 and 073. A more thorough description of the contents of these registers is given in Table 3-2 of Reference 7.

The DMA Throttle Select is used to select the number of Multibus accesses that must be completed between consecutive DMA transfers by the Multibus Interface. A selectable range of 0-15 transfers is provided. The standard is 1 host Multibus cycle between interface DMA cycles. This is contrary to the explanation given in Section 2.3.3 of Reference 7. In this section, the DMA throttle is presented in terms of "number of processor cyles" instead of Multibus accesses.

4. Command Packet Execution

To execute an operation contained in a command packet, the host computer must first test the Packet Address Ready Flag (port 070) which indicates whether the RDW is ready to accept and process command packets. If this flag

is set (1), the host loads the extended address bits (bits 17-20) of the command packet into the Command/Status Register (port 070). Then the least significant byte followed by the most significant byte of the 16-bit address of the command packet must be loaded into the Packet/DMA Register (ports 072 and 073 respectively). This sequence must be followed exactly because once the most significant byte is loaded into port 073, the interface board signals the RDW that the address is complete and ready to be transferred.

Upon receiving this signal, the RDW will read the address which was placed in the ports of the interface board, fetch the command packet located at that address, and perform the operation specified in the function code block of the packet. When the operation is complete, an entry is made into the command packet status word (word 0) indicating the success or failure of the operation.

## E. ICS-80 INDUSTRIAL CHASSIS

The iCS-80 Industrial Chassis consists of four (4) four-slot iSBC 604/614 Cardcages, four fans, a power supply, a control panel and a 19" RETMA (Radio-Electronics-Television Manufacturers Association) -compatible chassis. The control panel consists of an on/off/lock key switch, interrupt and reset pushbuttons, and halt/pwr on/run LED's.

The development system was designed to support a modular microcomputer-based system. Any combination of plug-in

modules which are Multibus-compatible may be installed including single board computers, memory expansion boards and peripheral interface boards. The iSBC 604 Cardcage can accomodate four (4) iSBC circuit boards and has an external plug which allows additional iSBC 614 Cardcages to be added to the chassis. The laboratory system used in support of this thesis is composed of a single iSBC 604 Cardcage and three (3) iSBC 614 Cardcages which allow a total of 16 circuit board slots. These cardcages comprise a backplane assembly that conforms to the Intel Multibus specifications and provides slots for both Mutibus master and slave boards. The master slots are odd-numbered and the slave positions are even-numbered for easy reference.

A master board is one which is capable of acquiring and controlling the Multibus, while a slave board can only be referenced by commands on the Multibus (i.e. memory expansion boards). The iCS-80 Chassis can be used with master boards operating in either a serial or parallel priority resolution scheme. In the serial mode, Multibus access contention is resolved by the board placement within the cardcage. However, an external priority resolver network is required to implement the parallel priority scheme. In this implementation, a random priority network is used to arbitrate the contentions for the Multibus. Most importantly, one of the above priority resolution schemes must be implemented or the interaction among the iSBC boards

in the cardcages will not be correct. For further information consult References 9, 10, and 11.

# IV. SYSTEM DEVELOPMENT

## A. INITIAL EFFORTS

### 1. Program Development System

During the initial stages of this thesis, it was planned to expand the work done by Hicklin and Neufeld [Ref. 2] to incorporate the REMEX Data Warehouse memory storage unit. They had developed a reconfigurable "table-driven" CP/M-86 BIOS that supported the MBB-80 Bubbl-Board and the Intel 1202 double-density floppy disk controller. It was initially believed that other I/O peripheral devices could be easily included in this BIOS with a minimum of effort. Within the proposed development system, the MBB-80 would serve as the principal storage medium for newly designed programs and would provide an easy method of booting Hicklin and Neufeld's CPM.SYS within the iCS-80 chassis.

However, this development strategy had several deficiencies. Utilizing this hardware/operating system configuration, program development would be limited to the MDS or iCS-80 systems and the CPM-86 utility programs which they supported. Presently, the only compatible text editor available is the text editor distributed by Digital Research, ED.CMD. This editor is very primitive, extremely hard to use, and completely unsatisfactory for extensive

program development. Therefore, an alternative development system was required.

It was decided to use the WORDSTAR text editor on the MP/M Multi-user System to create the needed software programs. This system provided several advantages over the MDS system. First, WORDSTAR offers functions which would significantly increase productivity and allow errors to be quickly corrected. Second, MP/M-compatible versions of ASM-86 and GENCMD utilities would enable programs to be written, assembled, corrected, and converted into executable CMD files prior to their transfer to the bubble memory. Third, since the MP/M system is a multi-user system, it did not present the availability problems associated with the single-user systems such as MDS.

Ultimately, this software development scheme also proved to be unsatisfactory, as numerous steps had to be taken to move an assembled program from the MP/M system to the MBB-80 board. Since only MP/M and MDS single density diskettes were compatible, assembled programs first had to be transferred from the MDS single density system to the MDS double density system using the laboratory utility program SDXFER.COM. This required that the MDS double density system be configured with an Intel 8080 processor. Once the program was transferred to a double density diskette, the MDS double density system had to be reconfigured for use with the MBB-80 bubble board and an iSBC 86/12A. After

reconfiguring, the program could now be transferred from the double density diskette to the bubble memory. At this point the MBB-80 was physically moved to the iCS-80 chassis. Finally, the operating system could be loaded and the program executed under DDT86.

Besides being time consuming, the above process monopolized much of the laboratory's equipment. Thus, if the equipment needed to make the transfer was in use, program testing could not be carried out. However, initially, it was the only method available and therefore had to be employed.

2. Verify MBB-80 Operation

The objective of this section was to verify the proper operation of the CPM.SYS developed by Eicklin and Neufeld. The double density MDS system was configured with a single iSBC 86/12A (#1), the MBB-80 bubble memory, and the i202 Floppy Disk Controller. The system was successfully booted from the 957 Monitor in accordance with the procedures given in Reference 11 by executing the command GFFD4:0. However, the bubble memory could not be accessed using any of the CP/M built-in commands. After inspection of the BIOS, it was evident that the final version of the CP/M-86 BIOS submitted did not support the MBB-80. Therefore, the CPM.SYS had to be reconstructed.

The files DKPRM.DEF and CONFIG.DEF were first checked to ensure that the desired hardware configuration

was accurately reflected in the Disk Definition Tables, the Disk Tables, and the Bubble Tables. Once this was completed, the file MBBIOS.A86 was reassembled and was then concatenated with CPM.H86 using PIP.COM. The resulting hex file was then converted to an executable CMD file and renamed CPM.SYS.

To ensure that all possible errors were avoided prior to system initialization, it was decided to reformat the MBB-80. The program MB80FMT.CMD was executed, inserting 8000h as the MBB-80 controller base address. Once formatted, the CP/M loader program MB80LDR.CMD was placed on tracks 0 and 1 of the MBB-80 utilizing the LDCOPY.CMD utility. The reconstructed system was booted and functioned normally.

3. Modification of the BIOS for Use in the iCS-80

As envisioned in the program development process, new programs would be transferred to the MDS double density system using a laboratory utility program. These programs could then be placed on the MBB-80. The MBB-80 would then have to be physically moved to the iCS-80 chassis. By entering the command GFFD4:4, CP/M-86 could be booted and the programs executed under CP/M or DDT86.CMD. However, since the MBB-80 would be the sole memory storage device in the iCS-80 chassis, a new modified BIOS had to be constructed.

The changes that needed to be made were located in two major areas of the BIOS. First, the file DKPRM.DEF which contained the disk definition statements for each logical CP/M disk drive had to changed. The number of logical devices was changed to 1 and the disk definition statement for the MBB-80 was entered as CP/M logical drive 0 (Drive A:) indicating that the MBB-80 was the only "drive" in the system. The other changes were made to the Disk and Bubble Tables contained in the file CONFIG.DEF. Ecklin and Neufeld had created these tables to identify whether CP/M logical drive numbers where either MBB-80 devices or i202 controllers. These tables would support any hardware configuration of MBB-80's and i202 contollers up a total of 16 disk drives (maximum for CP/M). However, other peripheral devices such as the REMEX Data Warehouse could not be supported as was initially believed.

Once these changes had been made, the BIOS was reassembled and used to create a new CPM.SYS which was placed on the bubble memory. It was subsequently tested and it functioned normally.

4. REMEX Low-Level Routines

Concurrently with the work on the MBB-80, low-level read/write routines were written and executed which accessed the REMEX Data Warehouse memory storage unit. This work was accomplished on the iCS-80 chassis using an iSBC 86/12A single board computer and the REMEX Multibus Interface Card

Assembly. At first only the most primitive operations were performed, since there was no permanent memory in the system. Using the 957 Monitor program, small programs were executed to examine the various values contained in the interface status registers. Once the new MBB-80 CPM.SYS was available, more comprehensive programs were written which could build command packets, transmit command packet addresses to the interface board, and check the packet status word for function completion. The basic logic of the read/write functions was discussed in greater detail in Chapter 3 and the logic diagram is shown in Figure 4.1.

A command packet was built which would write a very simple set of characters to a particular head, track, and sector number of the REMEX hard disk or a track and sector number on the floppy diskette. Using DDT86.CMD, the command packet was then altered to produce a read operation which would retrieve the previous message from the RDW and write it to a selected memory address. DDT86.CMD was also extensively used to monitor packet construction and memory content. With each successful transfer, larger blocks of data were transferred until it was concluded that the operations were being correctly performed. Although some progress was made, the program turn-around time resulting from the lack of an adequate development system definitely impeded further progress.

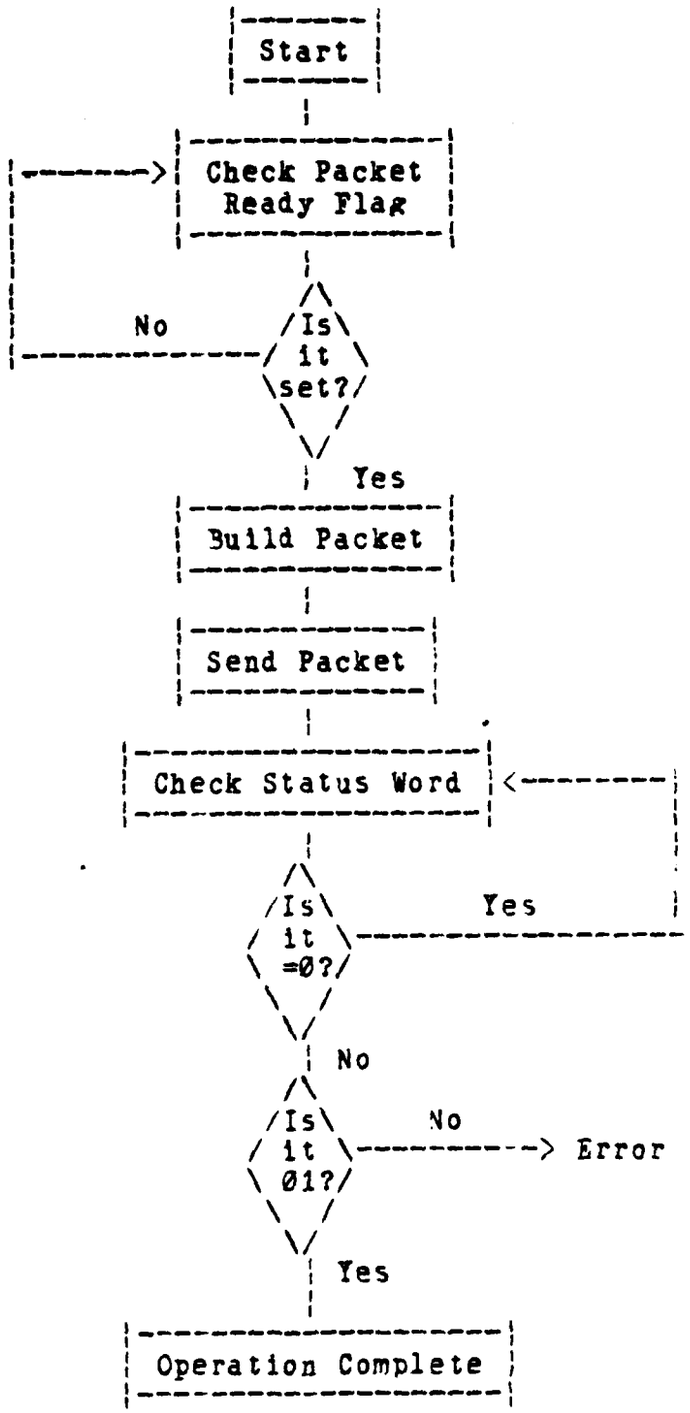

Figure 4.1
RDW Read/Write Logic

## 5. Table-Driven BIOS

The development mechanism that had been used up to this point was tedious and time-comsuming. The time required to repair errors discovered while working on the iCS-80 was too excessive to support cohesive program modification. It also became evident that the concepts used by Hicklin and Neufeld in the development of their BIOS were not sufficient to meet the objectives of this thesis. Although it was presented as a model for a very flexible system, the BIOS actually only supported MBB-80 bubble memories and i202 floppy diskette controllers. Inclusion of additional peripheral devices would have required major modification to the BIOS. Furthermore, even if these modifications were made, each time a device was added or deleted from the system, the code within the BIOS for the individual function calls would have had to be changed. The many inconveniences of the program development procedure coupled with the limitations of the Hicklin and Neufeld approach in a varying hardware environment necessitated a new BIOS design strategy.

Hammond [Ref. 3] had identified that certain device specific code could be extracted from the "core" of the BIOS without affecting function operation. This was accomplished by indirectly vectoring BIOS calls to the proper subroutines via a table of labels. Hammond had extracted the READ, WRITE, and INIT BIOS functions and constructed the

appropriate tables in a separate file named CONFIG.DEF. This file was then assembled with the BIOS by means of an "include" statement.

Next, let us examine the READ function in greater detail to see exactly how this BIOS works. Figure 4.2 contains the code for the READ function in the "core" BIOS for a hardware configuration consisting of an i201 Floppy Disk Controller.

```
read:
        xor  bx,bx
        mov  bl,unit
        add  bx,bx
        call readtbl[bx]
        ret
```

Figure 4.2
Table-Driven BIOS Read Code

This controller supports two floppy disk drives which correspond to CP/M logical drives 0 and 1. This correspondence is set up in the Disk Definition Tables. Also prior to the BDOS call to the BIOS READ function, the desired drive number has been stored in a BIOS variable called "unit". The value of "unit" is first placed in the "bl" register. Next, it is doubled since each label in the read_table represents the 16-bit address of the device-specific read functions. A call is now made to the read_table using the offset contained in the "bx" register. This table entry then indirectly addresses the appropriate subroutine for the desired "unit". For example, if CP/M

logical drive 1 (B:) is selected, the read call is indirectly addressed to the subroutine label located at an offset of two (2) in the read_table. The read_table is shown in Figure 4.3. Notice that since both CP/M logical drives are floppy disk drives, the read call is vectored to the same subroutine.

```
readtbl dw offset i201_read
        dw offset i201_read
```

Figure 4.3
BIOS Read Table

Through the use of a table-driven BIOS, the configuration flexibility needed for this application could be achieved. The use of the indirect call allows all device specific code to be isolated in a single file. Therefore, a separate file can be constructed for each unique peripheral device and can be included in the BIOS by the use of the "include" assembly command. An additional benefit of this type of approach is that it allows for the systematic addition or deletion of hardware devices to or from the system without disturbing the basic BIOS code.

The table-driven concept also provided an improved program develpment scheme and a more logical approach for the implementation of the REMEX Data Warehouse memory unit. Hammond had previously written the code to support the Intel i201 Floppy Disk Controller. A spare i201 controller was

available and was placed in the iCS-80 chassis. With a few minor modifications to the BIOS, it was operational in a very short time. Since both ALTOS and MDS single-density diskettes were fully compatible, programs could now be written, assembled, and converted to executable code and then be taken directly to the iCS-80 for execution. This reduced the amount of time needed to correct errors or modify a program and greatly facilitated code generation.

Because devices could be added to the BIOS independently, it was decided to utilize the 1201 floppy disk drive as a developmental aid and to subsequently implement the REMEX floppy disk first followed by the hard disk. The MBB-80 would be substituted for the 1201 once the REMEX interface was completed. This implementation scheme is explained in more detail in the following sections.

## B. INTERFACING THE REMEX DATA WAREHOUSE

### 1. Floppy Disk Drive

During the testing of the initial REMEX READ/WRITE low-level routines, it was observed that the REMEX would only intermittently complete a packet operation. When it did not complete successfully, the program looped infinitely checking the packet status word (see Figure 4.1) for a value other than a zero, indicating that the REMEX had either completed the operation or that an error had occurred. When multiple packets were sent out on the Multibus, completion

codes were occasionally returned in the command packet status word. When DDT86 was used to trace through the Read routine step by step, the same results were obtained. However, this procedure did verify that command packets were being constructed properly and that the packet address was being transmitted to the Multibus correctly.

Next, a Multibus Monitor Board was used to observe the action on the Multibus and confirmed that all data was correct. This led to speculation that either the interface board was not transmitting the correct information to the REMEX or the REMEX was not processing packets correctly once it received the information from the interface board. However, further hardware testing revealed that both the REMEX and the Interface were functioning normally.

The source of the problem was found more by accident than by design. Documentation [Ref. 8 : p. 2-4] indicated that the Interface Assembly would wait from 0 to 15 host CPU cycles between consecutive DMA operations. The exact number of cycles can be jumper selectable by the DMA Throttle. Therefore, polling the packet status word for a completion code was thought to provide sufficient CPU cycles to allow the process to continue. However, when the wiring diagram of the Interface Card Assembly was examined, it was discovered that the DMA Throttle was controlled by the number of Multibus cycles and not by the number of CPU cycles. Since the Throttle was set to the factory default

position, one additional Multibus cycle was required before the interface board could execute its next DMA operation. Because there was only a single host computer in the system, no additional Multibus accesses were made. This explains why marginal success was obtained by sending multiple packets since this provided the additional Multibus accesses. The DMA Throttle jumper was removed which allowed the Interface Card Assembly to respond immediately with a DMA operation once it acquired control of the Multibus. Subsequent packet operations were successfully completed.

Once the READ/WRITE driver routines had been debugged, the next step in the floppy disk implementation was to incorporate these routines into the table-driven BIOS. A separate "include" file called RXFLOP1.A86 was established to contain the necessary device-specific subroutines. Of the seven BIOS functions that had to be addressed, only the READ and WRITE functions required code in addition to that contained in the basic BIOS routines. Each of the other functions were returned directly to the main BIOS.

The command packet was allocated memory space in the data section of RXFLOP1.A86. However, the packet parameters had to be supplied from the BIOS variables in order to access the file requested by the CP/M file manager. Figure 4.4 depicts the READ packet for the REMEX floppy disk drives used in this implementation.

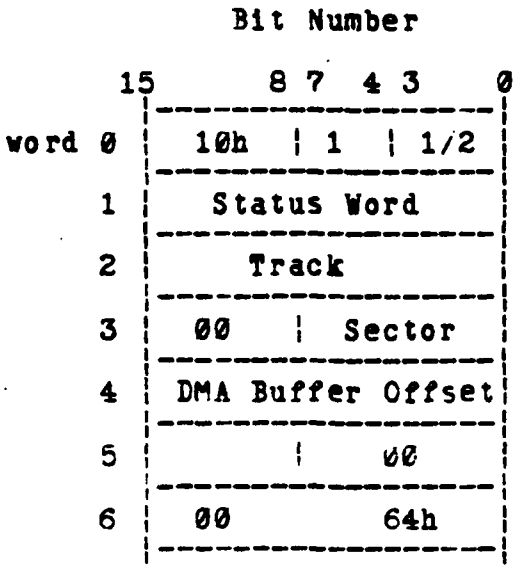

Figure 4.4
REMEX Floppy Disk Read Packet

From Chapter 3, recall that word 0 of the command packet is composed of a modifiers section, function code block, and unit id number. The value of 10h in the modifiers section merely indicates that a single packet is being sent and that all automatic error routines are in effect. The function code block (1) specifies a READ operation. Since the REMEX floppy disk drives were chosen to be equivalent to CP/M logical disk drives 1 and 2 (B: and C:) for this implementation, the CP/M drive number and the REMEX unit id for the two floppy disk drives were equivalent. Therefore, the desired CP/M disk number is directly inserted into the packet. The 16 -bit BIOS variable "track" which contains the requested track number is placed into word 2 of the command packet. Word 3 which contains the head and selected sector

number is formed by inserting a zero in the upper byte indicating that the floppy diskette will only be addressable on a single side and placing the BIOS variable "sector" in the lower byte. The 20-bit address of the CP/M DMA buffer which will receive the requested data is computed from the DMA base and offset. The extended address bits (bits 16-19) are entered in the lower byte of word 5. For example, if the local memory of an iSBC 86/12A is configured to respond to Multibus memory segment zero, the extended address bits will be equal to 00h. However, if the local memory were configured to respond to Multibus memory segment 1000, then the extended bits would be 01h. The remaining 16-bit address is placed into word 4 of the command packet.

Word 6 which contains the transfer word count caused the most problems with the floppy disk interface. The major difficulty encountered was the direct result of poor and misleading documentation. The REMEX technical manual for the interface board indicates [Ref. 8 : p. 2-4] that the REMEX can selectively transfer data to the host computer in either 8-bit or 16-bit words by setting a single switch. Since CP/M works with 8-bit words, the switch was set accordingly and a transfer word count of 128 8-bit words was placed in the packet and sent to the REMEX. At first, this seemed to work correctly because a directory of the diskette was read without difficulty and files could be transferred to and from the diskette without error. However, problems

were encountered when attempting to execute a file that was on the diskette. An error message of "FILE NOT FOUND" was displayed intermittently. If a file was found, the program would not execute correctly. In both cases, the system partially crashed and no other operations could be accomplished, despite the fact that the prompt character continued to function normally along with an occasional error message.

The source of the problem was not readily apparent. The operating system worked correctly until the directory of the REMEX floppy diskette was obtained or a file was executed. However, no error code was being generated by the REMEX. In fact, the success code that was being generated indicated that the operation and data transfer was being correctly accomplished. Executing the routines using DDT86 also indicated that the REMEX was functioning correctly and showed that the data was being placed in CP/M DMA buffer.

Numerous changes and experiments were made attempting to locate the cause of this problem. Printouts of the diskette's directory were obtained without error. Hardware was tested and retested with negative results. Finally, a memory map of the operating system was printed after obtaining the directory from a diskette in the MDS single density disk drive system. This was compared to a memory map of the operating system after the directory of

the same diskette was taken from the REMEX floppy drive. It was here that the error was uncovered. The REMEX was transferring 256 8-bit words into the DMA buffer space, not the 128 8-bit words as believed. Thus, the extra data was overwriting portions of the CP/M-86 BIOS causing the system to partially crash. The problem stems from the fact that the REMEX wants to know how many 16-bit words it should transfer. This is completely independent of how the REMEX will transmit the data. Therefore, since a CP/M sector of 128 bytes is equivalent to 64 or 40h 16-bit words, 40h was placed in word 6 of the command packet and no further problems were encountered.

2. Hard Disk

Although the implementation of the hard disk was very similar to the floppy disk drives, there were some notable exceptions. First, the REMEX had a sector size that was a multiple of the standard CP/M sector size of 128 bytes. This necessitated the use of a sector blocking/deblocking routine to resolve this disparity. Second, since the REMEX hard disk has four (4) separate heads, the question of how to divide up the disk had to be resolved. The most logical and straightfoward method was to let each head represent a separate CP/M logical disk drive. Each drive would then be able to address up to 4.5 megabytes of data. With these ideas in mind, the hard disk interface was begun.

Changes had to be made to the Disk Definition and Configuration Tables. In the file CPMMAST.DEF, CP/M logical drive numbers 3, 4, 5, and 6 were added to the table. Each drive number had a disk definition statement that described the physical storage capabilities of a single head of the hard disk. The disk definition variables were determined as presented in Chapter 3. Now, the BIOS would support a total of seven (7) peripheral I/O devices: an i201 floppy disk drive, two REMEX floppy disk drives, and four REMEX hard disk drives. Later, the MBB-80 bubble memory would be substituted for the i201 disk drive. Also, additional labels had to be added to the tables in the file CPMMAST.CFG to vector the BIOS function calls to the appropriate subroutines located in the "include" file RXHARD1.A86.

The most difficult obstacle to overcome in this portion of the implementation was to determine the REMEX hard disk sector size. The sector size can be either 128, 256, 512, or 1024 bytes. Initially, attempts were made to reformat the hard disk in accordance with Reference 7. Switches S1 and S2 located on the Formatter II Card Assembly were set to configure the hard disk with a 512 byte sector size. A program was then written which built a command packet to execute the REMEX built-in formatting routine [Ref. 7 : p 3-20]. However, repeated attempts failed to produce a successful format operation. The REMEX also supports a built-in maintenance program that tests the Hard

Disk Format operation. When this program was run, multiple error messages were returned indicating that the format program was inoperative.

Since data had been written to and retrieved from the hard disk during low-level driver testing, it was obvious that the REMEX had been previously formatted. The next step was to determine exactly what format was used. This was not as easy as might be expected. During the power up sequence, the REMEX will check the sector size switches and configure its internal circuitry to process sectors of that size even if the switch postions do not represent the actual format of the hard disk. That is precisely why these switches must match the actual physical sector size in order for read/write operations to work correctly. This fact caused considerable confusion in the interpretation of the error messages obtained by attempting to access the border sectors (104, 67, 39, and 21 for sector sizes of 128, 256, 512, and 1024 bytes respectively). However, it was finally determined that the sector size was 512 bytes.

Since the REMEX sector size was a multiple of the 128-byte CP/M sector size, a sector blocking/deblocking routine was needed to coordinate the access of CP/M sectors with the physical sectors of the hard disk. In this case, there were four (4) CP/M sectors contained on each hard disk sector. On each BIOS call, the CP/M-86 BDOS includes information that can be used to provide effective sector

blocking and deblocking. The sector blocking/deblocking routine used in this implementation is distributed by Digital Research in skeletal form [Ref. 6 : p. 70].

The blocking/deblocking algorithms map all CP/M sector read and write operations through an intermediate buffer called "hstbuf". The size of this buffer is equivalent to the REMEX sector size (512). During a read operation, a 512-byte sector of data is read into the "hstbuf" or host buffer from the REMEX hard disk. Since the host buffer now contains four CP/M sectors, the desired 128-byte sector is obtained by correctly offsetting into the host buffer. This data is then transferred to the CP/M DMA buffer defined by the DMA base and DMA offset variables. Similarly, during a write operation, four CP/M sectors are written to the host buffer. The data is then transferred to the REMEX hard disk and stored on a single 512-byte sector.

Within the blocking/deblocking routine itself, the values and variables which relate to CP/M sectors are prefixed by "sek", while those related to the REMEX hard disk are prefixed by "hst". The SELDSK, SETTRK, SETSEC, SECTRAN, and SETDMA entry point routines were transposed into the REMEX hard disk "include" file. These subroutines store values for later use and SECTRAN translates CP/M sector values into the corresponding physical sector. The READ and WRITE entry point labels were placed in the read_table and write_table respectively, while the actual

REMEX hard disk read and write low-level drivers were incorporated at the READHST and WRITEHST entry points.

The command packet was constructed from the following variables: "hstdsk" which represents the host disk number, "hsttrk" which is the host track number, and "hstsec" which cooresponds to the host sector. The host disk number is transformed into the appropriate head number and is entered into the upper byte of word 3 of the command packet. The memory segment and offset of the host buffer (hstbuf) is translated into a 20-bit address. The extended bits (16-19) are entered into the lower byte of word 5, while the remaining 16-bit address is placed in word 4 of the command packet. For the REMEX hard disk, we want to transfer 512 bytes or 256 16-bit words. Therefore, the

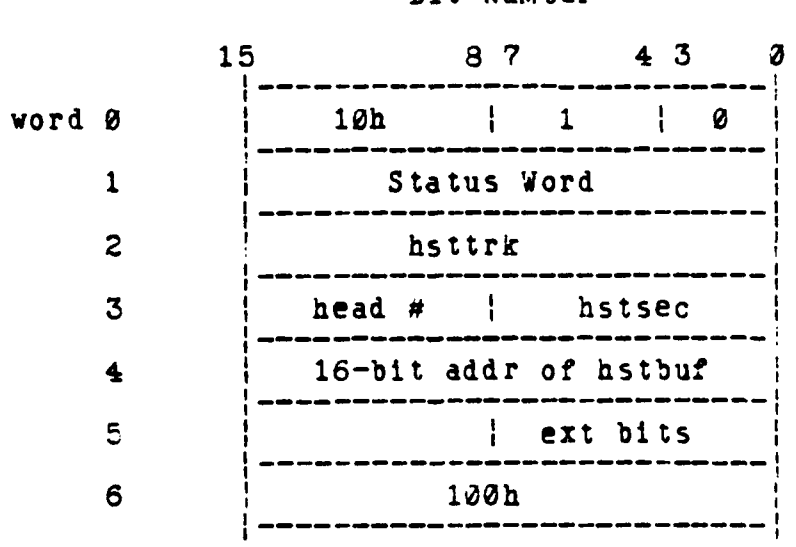

Figure 4.5
REMEX Hard Disk Read Packet

transfer word count (word 6) was set to 100h. The REMEX hard disk Read packet is shown in Figure 4.5.

### 3. Initial Multi-iSBC 86/12A System

The above implementation produced a CP/M-86 BIOS that supported the MBB-80 bubble memory and the REMEX Data Warehouse floppy and hard disk drives. The original master iSBC 86/12A (#1) was booted from the MBB-80 and had its onboard memory switch-and-jumper selected to be accessible from the Mulitibus beginning at memory segment zero. Data transferred from the REMEX would be put directly into the CP/M DMA or Host Buffers via DMA operations. The next step was to introduce a second iSBC 86/12A into the system which would also utilize the CP/M-86 operating system.

It was decided to use the 32K common memory to hold a bootloader program that could be used by the slave iSBC 86/12A computers to boot the CP/M-86 system. A utility program, LDCPM.A86, was written to place a copy of CP/M-86 into common memory which was especially configured for the slave computers. A second utility, LDBOOT.A86, was used to transfer a copy of the bootloader program (BOOT.A86) into common memory. The resulting common memory map is shown in Figure 4.6. CPMSLAVE.CMD was identical to the CP/M-86 system used for the master iSBC 86/12A except that it supported an iSBC 86/12A whose local memory was accessible from the Multibus beginning at memory segment 1000h. When initiated from the iSBC 86/12A monitor, the bootloader program would

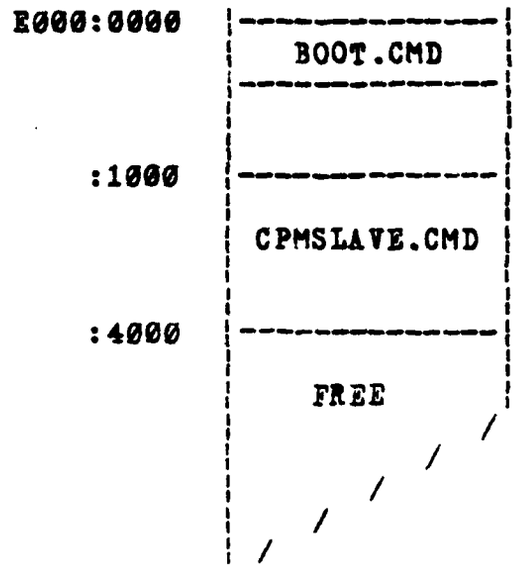

Figure 4.6
Common Memory Map

transfer the CP/M-86 slave system from common memory into local memory beginning at 40:0000h. Once the transfer was complete, control would be passed to the BIOS to initialize the system. It must noted that all these programs must reside on CP/M logical drive D:.

This scheme, although utilizing the DMA capability of the REMEX to the maximum extent possible, would require a different CPMSLAVE.CMD file for each iSBC 86/12A added to the system. Each computer's local memory would have to be placed in a separate 64K block within the one-megabyte address space available to the Multibus and these page numbers would be have to be entered in the lower byte of word 5 in the command packet. This organization is somewhat awkward and exhausts a large portion of common memory if

several computers are used. Therefore, a more acceptable alternative was needed.

## C. SYNCHRONIZATION AND PROTECTION

### 1. Synchronization of Read/Write Operations

With two active iSBC 86/12A computers in the system, the synchronization of read/write operations had to be addressed. Since the REMEX could queue up to eight (8) command packets internally, it was initially felt that this feature would provide adequate synchronization of the I/O requests from the independently operating computers. However, when simultaneous multiple transfers were attempted between the CP/M hard disk logical drives, sporadic errors occurred. Inspection of the READ and WRITE routines in the hard disk "include" file (RXHARD1.A86) revealed that there was nothing to prevent a clash of both iSBC 86/12A computers if they simultaneously attempted to send a command packet address to the REMEX Interface Card Assembly. Since the packet addresses were sent in three (3) single-byte Multibus transfers, it was indeed possible for the values sent to the interface board to become intermixed. Also, once the most significant byte of the packet address is sent, the interface immediately signals the REMEX that the packet address is complete and ready to be transferred. However, this may not be the case. Consider the case where computer #1 has transferred the extended address and the least significant bytes of the packet address to the Packet/DMA

Register. Computer #2 then sends the extended bits of its packet address. Since each computer's memory begins on a different page, the extended bits will be different for each iSBC 86/12A. Computer #1 now regains control of the Multibus and sends its most significant address byte. The Remex will now read the packet located in computer #2's address space rather than the packet in computer #1's address space. This will certainly cause severe problems.

Initially, the section of code used to send out the packet address was identified as a critical section. A semaphore was then defined to control the access to the critical section. In order that all active iSBC 86/12A computers could have access to the semaphore, it was placed in common memory and could take on a value of either 0 or 1 indicating that the resource was either busy or free respectively. If it was a 1, the requesting computer would set it to 0, send the three bytes of the packet address, and then reset it to 1. If the requestor found that the semaphore was equal to 0, it would delay and then recheck. This checking process was implemented using the LOCK XCHG instruction to provide exclusive use of the Multibus.

When simultaneous multiple file transfers were again attempted, errors still occurred indicating that there was still some interference on the Multibus. This probably occured when the registers of the interface were set up for a DMA data transfer and a packet address was then written

into the Packet/DMA register before the data could be transfered. At any rate, a more inclusive synchronization scheme was required to ensure that a single iSBC 86/12A read/write operation could be completed without encountering contention from the other computers in the system.

Since it was desirable to have all iSBC 86/12A computers configured alike, it was decided to adopt a software approach to the synchronization problem rather than the conventional monitor approach. The method chosen was based on sequencers and eventcounts [Ref. 12]. This method is modeled after the "ticket/server" system used in many stores where services are performed. When the customer arrives, he takes a numbered ticket and then waits for his number to come up before being served. The server works in ticket number order. The implementation of this scheme is very straightfoward and had been previously used by Hammond [Ref. 3]. Two 16-bit counter variables, "ticket" and "server", were placed in common memory. The value 0 was reserved for the ticket number indicating that another computer was presently modifying the ticket number. Exclusive access to the ticket number was provided by the LOCK XCHG instruction. An algorithmic language representation of the sequencer routine is given in Figure 4.7. The delay used in the Await Subroutines was used to prevent Multibus contention. "Request" is called prior to each read or write operation to gain exclusive access to the

```

**********************************************************************

        request:                ;get resource

                        call ticket
                        call await
                        ret

----------------------------------------------------------------------

        release:                ;release resource

                        call advance
                        ret
```

Figure 4.7
Sequencer Algorithm

shared resource. Once the operation is complete, "release" is called to free the resource by incrementing the server number which allows the next I/O function to be executed. When the sequencer code was implemented into the read/write routines for each of the peripheral I/O devices, no further errors were noted.

2. Common Memory Read/Write Routines

As alluded to earlier, the CP/M-86 BIOS which uses DMA operations to transfer data between the iSBC 86/12A computers and the Remex Data Warehouse requires a unique BIOS for each computer in the system. This places a severe limitation on further system expansion and complicates the system configuration control requirements. Futhermore, this type of implementation requires that at least a portion of the iSBC 86/12A's local memory be accessible to the Multibus. One of the principal goals of this thesis was to provide a system in which all computers were isolated from one another. Obviously, this implementation does not support this goal. It also results in an awkward bootloader arrangement in common memory and requires that all versions of CP/M-86 needed for system operation be accurately updated should any changes or modifications occur. Therefore, a more acceptable BIOS implementation had to be found.

The resulting implementation routed all data transfers through a common memory buffer. The size of this buffer was set to correspond to the largest physical sector

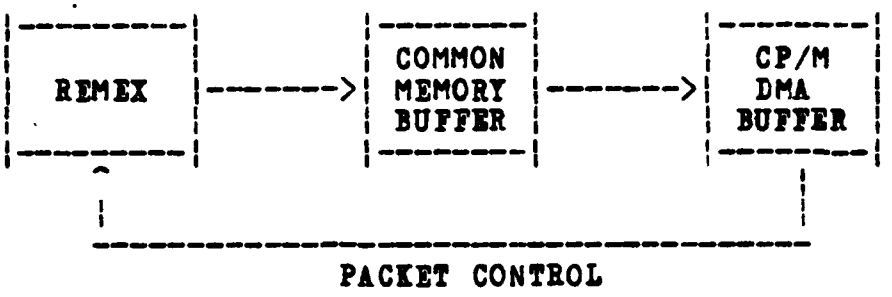

Figure 4.8
Common Memory Read Operation

within the system which was the 512-byte sector of the REMEX hard disk. The additional code required for each read/write routine was minimal since its only function was to transfer a given amount of data between local and common memory. A data flow diagram depicting a typical read operation from the REMEX is shown in Figure 4.8. For illustration, consider a CP/M initiated read operation from the REMEX hard disk. The command packet will be constructed as before except that the 20-bit common memory buffer address will replace the host buffer address in word 4 and the lower byte of word 5 of the packet. This will result in the desired data being read into the common memory buffer. When this operation is complete, the requesting iSBC 86/12A will then transfer the data in the common memory buffer to the host buffer located in the data section of the CP/M BIOS. This procedure is entirely transparent to the CP/M BDOS. A write operation is similarly completed. First, the data in the host buffer is written to the common memory buffer. Next, a packet is sent

to the interface which transfers the data from common memory to a specified head, track, and sector of the hard disk. The required changes were made to the "include" files for the MBB-80 bubble memory, the REMEX floppy disk drives, and the REMEX hard disk drives and the files were renamed MB80DSK.A86, RXFLOP.A86, and RXHARD.A86 respectively. These files appear in Appendices C, D, and E.

The common memory routines produced several improvements to the overall system design. First, all iSBC 86/12A computers could be completely isolated. Each of the four computers used in the system was jumper configured so that all onboard memory was reserved totally for local CPU use and could not be accessed from the Multibus. This provided the required protection for each computer's local

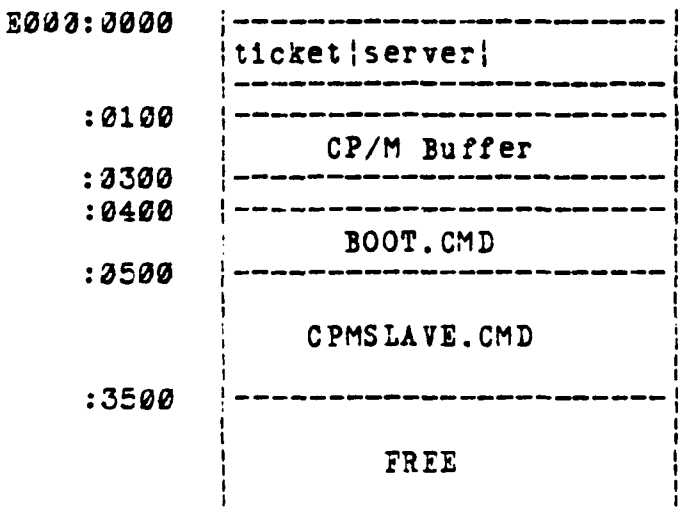

Figure 4.9
Common Memory Allocation

memory. Second, only a single copy of the CP/M-86 operating system was required for all of the slave computers since data transfers were locally initiated. In fact, the only difference between the slave and master versions involved the initialization of the synchronization variables and the log-table. A memory map showing the configuration of common memory is presented in Figure 4.9.

3. Disk Write Protection

The ticket/server synchronization routine ensures that single iSBC 86/12A read/write operations can be completed without interference. However, this is not sufficient to provide the necessary write protection to the shared devices in a system of multiple computers each running CP/M-86. Consider the case of two processors trying to write to the same CP/M logical disk. CP/M reads the disk directory and constructs an allocation vector in the BIOS that indicates the logical blocks on the disk that have not been written to previously. Each iSBC 86/12A then proceeds to write its data file to the unallocated blocks in sequential order. Although the individual write operations were synchronized, the result is still overwritten and garbled data. Therefore, this implementation institutes a read/write strategy that allows all computers to read data from all the shared devices but only write to a single device to prevent files from being overwritten. Moreover, it was also desirable to be able to select any of the shared

devices for write operations from each of the four system console positions.

A logon and logout procedure was developed to control the write access to the various peripheral devices through the use of a table located in common memory. This table has a entry for each device in the system (Figures 4.10 and 4.11). Before the user is permitted to boot the CP/M he is asked for his console number and the CP/M drive that he wishes to log onto (write to). The CP/M drive

| | A: | B: | C: | D: | E: | F: | G: |
|---|---|---|---|---|---|---|---|
| logtbl | MBB-80 | FLOP1 | FLOP2 | HARD1 | HARD2 | HARD3 | HARD4 |

Figure 4.10
Login Table

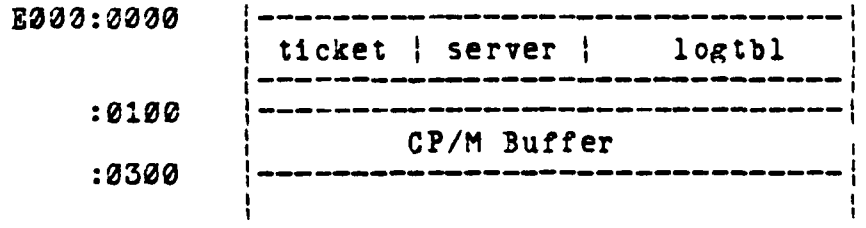

Figure 4.11
Final Common Memory Configuration

number is stored in a local variable called "user" which is used as an offset into the log table. The log table is then checked to determine if the desired disk has already been logged onto. If not, the console number is entered into the

log table at an offset corresponding to the given device. Otherwise, the user is asked to select another disk. To log out, the user types the command "logout" which places a zero (free) in the log table at an offset equal to the user number. Each CP/M logical disk drive requires its own copy of the log out routine (LOGOUT.CMD) so that it can be executed from every disk drive.

Within the BIOS, when a write operation is requested, the variable "user" is compared to the CP/M logical disk number. If they are equal, the write operation is permitted to continue. If not, the user is informed that write operations are not permitted to that disk drive. This guarantees that no two iSBC 86/12A computers can write to the same shared disk.

## D. SUMMARY OF SYSTEM GENERATION

The following descriptions provide step-by-step procedures on how to create the BIOS for this implementation of the CP/M-86 operating system, how to step up the MBB-20 bubble memory board in the MDS double density system, and how to start up the multi-user CP/M-86 system.

### 1. System Bios Creation

a. Develop separate files for each I/O device being sure to address the seven device specific functions in each. In this code, before any Multibus access include the command "call request" and upon completion of a Multibus access include the command "call release".

b. Ensure that all I/O is accomplished via the common memory I/O buffer which extends from E000:100 to E000:300. Develop a transfer routine for moving data to and from the common memory buffer and the host computer.

c. Decide upon the logical hardware configuration as will be seen by CP/M-86. Based on this configuration, develop the Disk Parameter Table which will be used as the source file for GENDEF.CMD to produce a ".LIB" file. Also, using this same hardware configuration and the I/O device files, develop the label tables in CPMMAST.CFG for the seven device specific functions.

d. In the BIOS use the "include" command for all I/O device files, the label table (CPMMAST.CFG), and the Disk Parameter Table (CPMMAST.LIB). The files SYNC.A86 and LOGIN.A86 must also be included, but require no modifications.

e. Assemble the BIOS using ASM86.COM. Using ASM86.CMD may generate forward reference errors and require the rearrangement of some included files in the BIOS. Two assemblies must be made. The first must be assembled with the master conditional assembly switch set to true in order to create the master BIOS. The second must be made with the switch set to false in order to create the slave BIOS.

f. Concatenate the resulting hex files with CPM.H86 to form CPMMAST.H86 and CPMSLAVE.H86. Use the CP/M utility

command GENCMD.CMD (GENCMD CPMMAST 8080 code[a40]) to generate the executable command files.

g. Transfer CPMMAST.CMD to the MBB-80 bubble memory board as CPM.SYS. Transfer CPMSLAVE.CMD to drive D: of the REMEX.

2. Setting up the MBB-80 in the MDS System

a. Remove the Intel 8080 microcomputer and the associated memory boards from the MDS double density system.

b. On the iSBC 86/12A #1, place the switches 1-16 and 8-9 on DIP switch S1 in the closed position. Install a jumper between pins 127 and 128. If there are jumpers in place for the clock, pins 103 and 105, remove them.

c. Insert the iSBC 86/12A #1 and the MBB-80 board with the backplane into the MDS chassis.

d. Turn the power to the MDS chassis and the disk drives on. Once these devices are running, apply power to the MBB-80 board by setting the memory protect switch on the backplane to the "run" position. Now, the CP/M-86 operating system can be booted from a double density diskette by entering the command GFFD4:0. The system booted should be one that is capable of addressing the bubble memory as a diskette.

e. To format the MBB-80 bubble memory execute the program MB80FMT.CMD and use 8000H as the base address for the controller. Execute LDCOPY.CMD using LDRMB80.CMD as the source file. This will place the loader on tracks 0 and 1

of the MBB-80 bubble board. Finally transfer CPMMAST.CMD to the bubble as CPM.SYS.

3. System Initialization

a. Insert four iSBC 86/12A computers into the iCS-80 chassis. One computer must have a jumper on pins 103/104 and 105/106. These connections supply the clock for the Multibus. All computers should have pins 112 and 114 connected by a jumper wire. This ensures that the computer's local memory is inaccessable to the Multibus. Also on all computers, only position 8-9 on DIP switch S1 should be closed. All other positions should be open. Finally, insert the MBB-80 bubble memory board, the 32K common memory board and the REMEX interface board into the iCS-80 chassis.

b. Turn the iCS-80 power switch on.

c. Power up the REMEX in accordance with Ref. 7 and turn the MBB-80 memory protect switch to "on". This switch is located in the rear of the iCS-80 chassis.

d. When the REMEX hard disk has timed out and the ready light is on, enter the command GFFD4:4 from the console attached to iSBC 86/12A #1 to boot CP/M-86 from the MBB-80. The synchronization variables and the log table entries will be initialized in common memory.

e. Select drive D:

f. Execute LDCPM located on drive D:. This will load the file CPMSLAVE.CMD into common memory starting at E000:500.

g. Execute LDBOOT located on drive D:. This will place the file BOOT.CMD into common memory starting at E000:400.

h. Now, CP/M-86 can be booted on any iSBC 86/12A computer by entering the command GE000:0400 from the monitor.

i. When a session is completed, enter the command LOGOUT to logoff the system.

# V. RESULTS AND CONCLUSIONS

## A. GENERAL RESULTS

The ultimate goal of this thesis was to develop a multi-computer "protected" CP/M-86-based system that shared memory storage devices. This goal was accomplished and the resulting code is located in the Appendices. The major product produced by this thesis is a completely operational multi-user development station. The CP/M BIOS is completely table-driven and can be reconfigured for different hardware configurations in under twenty minutes. This feature alone is a significant improvement over the standard BIOS marketed by Digital Research. In addition, it should be quite easy to expand the current system to permit more users or add additional I/O devices.

The system provides user protection in several forms. No user, once logged onto the system can destroy, either by design or by accident, anothers user's files or local CPU memory. However, any single computer can destroy common memory, but it is a simple matter to restore it. Furthermore, the logon and logout procedures prevent two users from simultaneously logging onto and writing to the same CP/M logical disk drive.

## B. EVALUATION OF THE IMPLEMENTATION

To evaluate system performance, two tests were conducted. The first test involved assembling a 3K and then a 24K file with a single computer logged onto the system. The assembly time was recorded using a conventional stopwatch. Next, two computers were used to simultaneously assemble the same file, followed by three and then four computers. The results of the test are shown in Table 5.1.

Table 5.1
REMEX Assembly Times In Seconds

| FILE SIZE | ONE COMPUTER | TWO COMPUTERS | THREE COMPUTERS | FOUR COMPUTERS |
|---|---|---|---|---|
| 3K | 12.9 | 22.1 | 25.1 | 28.8 |
| 24K | 211.1 | 246.7 | 257.3 | 275.5 |

Table 5.2
MP/M Assembly Times In Seconds

| FILE SIZE | ONE USER | TWO USERS | THREE USERS | FOUR USERS |
|---|---|---|---|---|
| 3K | 22.3 | X | X | X |
| 24K | 323.2 | X | X | X |

One might expect that two computers would take twice as long to assemble the same program and three computers three times as long. However, except for the initial contention for the I/O devices, all computers could assemble the files in parallel. This accounts for the fact that there is not a

linear relationship between the number of computers operating in the system and the assembly times.

To provide a means of comparison, an attempt was made to run the same test under the MP/M operating system. However, MP/M would not permit more than one file to be assembled at the same time. In fact, on several attempts, the entire system crashed. The results of this test are shown in Table 5.2.

The second test involved a file transfer utilizing the CP/M-86 utility PIP.CMD. Since all operations were I/O intensive, this test represented a worse case scenario. The first run consisted of transferring a 16K file with only one computer operating in the system and recording the time it took to complete the operation. Then two and finally three computers were used to execute the identical PIP command at the same instant. The time it took for all computers to complete the task was recorded. The results of these tests are shown in Table 5.3. The "Xs" indicate that it was not possible to make the transfer because there was an insufficient number of destination type devices. (i.e. Two computers cannot transfer files to a single bubble device at at the same time.)

To provide a comparison for the above results, the same test was run on the MP/M system. Although the two system configurations are different, they do offer some basis for comparison. However, in the MP/M system, only operations

between the hard disk and floppy disk were possible. The results of this test are shown in Table 5.4.

From these results, it can be seen that the multi-user CP/M-86 system has a slight performance advantage for single user disk operations. When more than one user is operating in the system, this performance advantage becomes very

Table 5.4
MP/M Transfer Times In Seconds

| FROM \ TO | HARD DISK | FLOPPY DISK |
|---|---|---|
| ONE USER EXECUTING PIP UNDER MP/M | | |
| HARD DISK | 7.3 | 12.0 |
| FLOPPY DISK | 11.2 | 14.8 |
| TWO USERS EXECUTING PIP UNDER MP/M | | |
| HARD DISK | 17.4 | 26.2 |

| THREE USERS EXECUTING PIP UNDER MP/M | | |
| HARD DISK | 23.7 | X |
| FLOPPY DISK | 36.9 | X |

significant for transfers made between areas on the hard disk. However, the REMEX floppy disk drives are slower.

Since the REMEX hard disk can be used to emulate the "signal processor" functions of the AEGIS system, a third test was conducted to determine the optimum skew factor for consecutive read operations. A low-level routine was written to continuously read sectors from the hard disk into common memory. After each read operation, a counter was incremented. When five read operations had been completed, a character was printed to the CRT screen. The time it took to print 80 characters to the CRT is recorded and

Table 5.5
REMEX Winchester Disk Skew Times
in Seconds

| SKEW FACTOR | TOTAL TIME | SKEW FACTOR | TOTAL TIME |
|---|---|---|---|
| 0 | 10.00 | 20 | 5.25 |
| 1 | 10.35 | 21 | 5.55 |
| 2 | 10.55 | 22 | 5.80 |
| 3 | 10.95 | 23 | 6.10 |
| 4 | 11.25 | 24 | 6.35 |
| 5 | 11.45 | 25 | 6.60 |
| 6 | 11.70 | 26 | 6.85 |
| 7 | 11.95 | 27 | 7.10 |
| 8 | 12.20 | 28 | 7.35 |
| 9 | 12.55 | 29 | 7.55 |
| 10 | 12.75 | 30 | 7.80 |
| 11 | 13.05 | 31 | 8.05 |
| 12 | 13.40 | 32 | 8.30 |
| 13 | 13.45 | 33 | 8.65 |
| 14 | 13.70 | 34 | 8.85 |
| 15 | 4.20 | 35 | 9.20 |
| 16 | 4.35 | 36 | 9.45 |
| 17 | 4.55 | 37 | 9.65 |
| 18 | 4.85 | 38 | 9.85 |
| 19 | 5.05 | | |

approximates the time it took to conduct 400 separate read operations. During the first run, the skew factor was set to zero. Therefore, no sectors were skipped between read operations. In the subsequent runs, the skew factor was incremented by one for each successive test. The results are shown in Table 5.5 and indicate that a skew factor of 15 is optimal for reading data from the REMEX hard disk.

## C. RECOMMENDATIONS FOR FUTURE WORK

There are several possible opportunities for future projects involving the REMEX hard disk and the multi-user

CP/M-86 system. The first and foremost is the use of the system to emulate the AEGIS system. Several AEGIS system modules have already been developed and could be run on dedicated iSBC 86/12A computers using the REMEX hard disk to supply simulated radar data. In the present hardware configuration, four system modules could be run concurrently.

However, there are other smaller support projects which would increase the capability and utility of the system. There is an urgent need for a more sophisticated text editor or word processor. Without one, the system will not be used to its full capabilities. Translating the 8080 assembly language code of BTED.COM into 8086 assembly language would provide a more usable text editor than the one currently provided by Digital Research - ED.CMD.

Another possible project is to develop a boot loader program for the REMEX Data Warehouse. As the system is currently designed, the CP/M operating system must be initially loaded from either the MBB-80 or from the MDS single density system. This would allow CP/M to be booted from any of the memory storage devices currently in the system.

A more ambitious project would be to design a boot loader which permitted the user to boot not only the master CP/M-86 operating system directly from the REMEX Data Warehouse, but the slave CP/M-86 operating system as well. This would relieve the master system of the task of loading

the CP/M slave system and the boot loader program into common memory prior to booting the other slave computers. Furthermore, it would free a larger portion of common memory for general use and decrease the number of system variables that would have to be reconstructed should common memory be destroyed. The programs LDCPM.A86, LDBOOT.A86 and BOOT.A86 which are already written could be combined to form the nucleus for such a program. Once operating correctly, the program would have to be loaded into an iSBC 86/12A EPROM where it would be accessible to the monitor.

The final project could alter the CP/M-86 BIOS to include the Micropolis Winchester hard disk, the MDS double density disk drive system, and the newly acquired 256K bubble memories. The code for the Micropolis hard disk and the MDS double density disk drive system has already been written and only needs to be put into the table-driven BIOS format. The implementation of the new bubble memories should be very similar to that of the MBB-80.

# APPENDIX A
# PROGRAM DISCRIPTIONS

## I. MBB-80 BUBBLE MEMORY FILES

A. MB80FMT.CMD: This program is used to initially format the MBB-80 bubble storage device as a single density disk drive. When the program is executed it will prompt the user for a segment address. The address of 8000 must be entered. The program will then set the controller base address to 8000h and write the correct byte patterns on the bubble memory system to give it the appearance of a diskette. [Ref. 2 : p. 88 and p. 159]

B. MB80ROM.A86: This file contains the source code necessary for bootstrapping the system from the bubble memory device. It has been loaded into an EPROM and placed on the motherboard of the iSCB 86/12A computer labeled #1. It is executed by entering the command GFFD4:4 into the monitor of the computer. The program will then place the system loader into memory and transfer control to it. [Ref. 2 : p. 187]

C. LDRMB80.CMD: This is the loader program that must be placed on the bubble's tracks 0 and 1. It will locate the file CPM.SYS on the bubble memory device, load it into memory and then transfer control to the operating system. The BIOS for this program is created using MBBIOS.A86 with the loader conditional assembly switch set to true.

D. MBBIOS.A86: This file contains the source code used to create the BIOS for both the CPM.SYS and the LDRMB80.CMD The CP/M.SYS BIOS is created with the loader conditional assembly switch set to false. [Ref. 2 : p. 166]

E. DKPRM.DEF: This file contains the hardware configuration tables for arranging up to 16 MBB-80 bubble memory devices or Intel MDS double density disk drive systems in any combination. It was used by Hicklin and Neufeld in their implementation of a "table driven" BIOS. However, different I/O devices (i.e. REMEX Data Warehouse) may not be added to their table. [Ref. 2 : p.95]

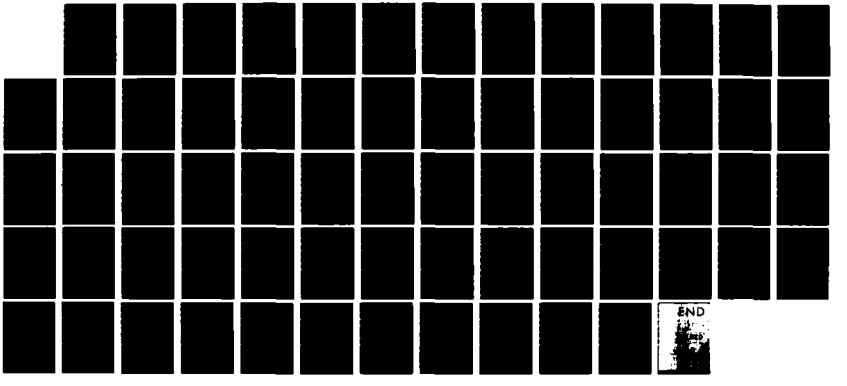
F. CONFIG.DEF: Contained in this file are the disk definition statements used by Hicklin and Neufield to generate the Disk Definition Tables for their BIOS. The file generated is labeled CONFIG.LIB and is included into MBBIOS.A86 when assembled. [Ref. 2 : p. 92] and [Ref. 6 : p. 67]

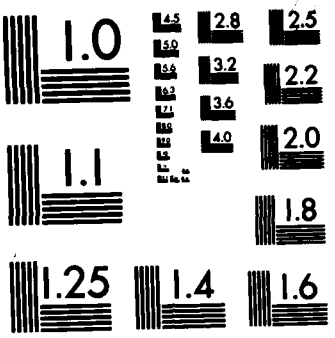
II. REMEX DATA WAREHOUSE FILES

A. CPMBIOS.A86: This file is the basic table driven BIOS used in this thesis. By setting the MASTER/SLAVE conditional assembly switch to either true or false, two different CPM.SYS's can be created. The only difference in the two is that the CPMMAST.CMD system contains code to initialize the synchronization and login variables located in common memory. The resulting MASTER file should be renamed to CPM.SYS and placed on the bubble memory storage

AD-A126 850 ALTERATION AND IMPLEMENTATION OF THE CP/M-86 OPERATING SYSTEM FOR A MULTI-USER ENVIRONMENT(U) NAVAL POSTGRADUATE SCHOOL MONTEREY CA T V ALMQUIST ET AL. 2/2

UNCLASSIFIED DEC 82 F/G 9/2 NL





MICROCOPY RESOLUTION TEST CHART
NATIONAL BUREAU OF STANDARDS-1963-A

device. Entering the comand GFFD4:4 from the iSBC 86/12A computer labeled #1 will boot the system.

When the MASTER/SLAVE conditional assembly switch is set to false, a slave system will be created. This system should be named CPMSLAVE.CMD. It is this file that is eventually loaded into common memory via the command LDCPM.CMD.

After the slave system has been loaded into common memory, the command LDBOOT.CMD must also be executed in order to place the loader program into common memory. Once these two commands have been executed, all other computers can issue the command GE000:400 to the computer monitor and the CP/M operating system will be loaded for each.

B. CPMMAST.CFG: This file contains the label tables for the seven I/O device-specific functions which are extracted out of the BIOS. These functions are INIT, SELDSK, HOME, SELTRK, SELSEC, SETDMA, and SETDMAB. A conditional assembly switch is located in the INIT table. When the master switch is set to true, two extra labels are included which permit the initialization of the synchronization and login variables in common memory.

C. MB80DSK.A86: Located in this file is the code necessary to read and write to the MBB-80 Bubbl-Board. It is assembled into the CPMBIOS.A86 file by an "include" statememt.

D. RXFLOP.A86: This file contains the code for reading and writing to the REMEX Data Warehouse's two floppy disk drives. It is assembled into the CPMBIOS.A86 file by the use of an "include" statement. Command packets for the REMEX are built in common memory and all DMA is accomplished through common memory.

The file labeled RXFLOP1.A86 is almost identical to RXFLOP.A86. The difference is that common memory is not used for DMA or packet building. Instead the REMEX directly accesses the host's on board memory. Thus RXFLOP1.A86 will only work for a computer which has its local memory address space between 00000h and 0FFFFh. To permit additional computers to use this code, the packet addresses built in this BIOS will have to be changed to correspond to the computer's memory address space within the system's addressable memory space of 1 Megabyte.

E. RXHARD.A86: This file contains the code necessary to access the Remex Data Warehouse's Winchester hard disk. It also contains the blocking and deblocking code required for mapping the REMEX's 512 byte sectors to CP/M's 128 byte logical sectors. It is assembled into the CPMBIOS.A86 file by an "include" statement. Command packets for the REMEX are built in common memory and all DMA is accomplished through common memory.

The file RXHARD1.A86 is almost identical to RXHARD.A86. The difference being that common memory is not used for DMA

or packet building. See RXFLOP.A86 for more detail, as changing RXHARD1.A86 to accomodate more than one user requires the same changes as RXFLOP1.A86.

F. CPMMAST.DEF: This file contains the CP/M-86 disk definition statments used in this thesis. It is the source file for GENDEF.CMD which produces the file CPMMAST.LIB.

G. CPMMAST.LIB: This file is assembled into the CPMBIOS.A86 via an "include" statement. It contains the Disk Parameter Tables created by the CP/M utility program GENDEF.CMD, using the file CPMMAST.DEF as the input file.

H. INTELDSK.A86: While this file is not included in the final hardware implementation of this thesis, it contains the code necessary for accessing the Intel MDS single density disk drive system. It was used extensively in the early developmental phases of this thesis because it provided an easy method of booting a new CPM.SYS. If this file is included into the CPMBIOS, the CP/M-86 operating system can be booted by issuing the command GFFD4:0 to the monitor.

I. LDCPM.A86: This program must be executed in order to load CPMSLAVE.CMD into common memory beginning at E000:500.

J. LDBOOT.A86: This program must be run before the slave CP/M system can be loaded by the other computers. When executed, the program BOOT.CMD will be placed in common memory beginning at E000:400.

K. BOOT.CMD: This is the loader program used by all but the initial computer to boot the CPMSLAVE operating system from common memory. It is executed by entering the command GE000:400 from the monitor after the programs LDCPM.CMD and LDBOOT.CMD have been run.

L. RXFORMAT.A86: When an I/O device is first initialized for use under the CP/M operating system, the hex code E5's must be written on the tracks which will contain the directory, otherwise the error "NO DIRECTORY SPACE" will occur. This program will write E5's on the necessary tracks for each head of the Winchester hard disk. Since executing this program will erase all files accessible to the different heads, it will prompt the user for permission to procede in order to insure that the files are not erased by mistake. Normally this program will not be of any use unless a new hard disk is installed or a directory track is inadvertently destroyed.

M. RXMAINT.A86: The REMEX Data Warehouse contains numerous built-in error checking and maintenance programs which can be implemented by building and then sending maintenance packets to the REMEX. This program prompts the user to choose one of these built-in maintenance programs and then runs the test. If an error is encountered, the error code is printed. The meanings of the error codes can be found in the REMEX technical manual. [Ref. 9 : p. 3-19]

N. LCGIN.A86: This file contains the code necessary to

provide protection from more than one user logging on to the same area of the hard disk or the MBB-80 board at the same time.

O. SYNC.A86: This file must be included in the BIOS when more than one computer is going to operate on the Multibus. It contains the code which prevents more than one computer from accessing shared resources while another is conducting a read or write operation through common memory.

## APPENDIX B
## PROGRAM LISTING OF CPMBIOS.A86

```
;Prog Name  : CPMBIOS.A86 (Master/Slave CPM Bios)
;Modified   : Inclusion of Synchronization Routine
;Date       : 7 October 1982
;Written by : Tom V. Almquist and David S. Stevens
;For        : Thesis (AEGIS Modeling Group)
;Advisor    : Professor Kodres
;Purpose    : This BIOS is for use with the iSB86/12A.
;           : It requires a separate include file for
;           : each different I/O device.

## PROGRAM LISTING OF RXFLOP.A86

```
;Prog Name   : RXFLOP.A86 (REMEX FLOPPY DISK
;                          ACCESS CODE)
;Date        : 9 October 1982
;Written by  : Tom V. Almquist and David S. Stevens
;For         : Thesis (AEGIS Modeling Group)
;Advisor     : Professor Kodres
;Purpose     : This code is an include file w/in CPMBIOS.A86.
;              It contains the code necessary to access the
;              Remex floppy disk drives. I/O done through
;              common memory. This configuration is set for
;              CP/M logical drives 1 (B:) and 2 (C:). To
;              alter, change code in READ and WRITE routines.

## APPENDIX G
## PROGRAM LISTING OF CPMMAST.DEF

The following disk definition statements were used in this thesis. The command "GENDEF CPMMAST.DEF" is executed to produce CPMMAST.LIB which must be assembled into the BIOS using an "include" command.

```
disks 7
diskdef 0,1,26,0,1024,71,32,0,2
diskdef 1,1,26,6,1024,243,64,64,2
diskdef 2,1
diskdef 3,1,156,0,16384,275,128,0,1
diskdef 4,3
diskdef 5,3
diskdef 6,3
endef
```

## APPENDIX H
## PROGRAM LISTING OF CPMMAST.LIB

When GENDEF is executed using CPMMAST.DEF as the source file, CPMMAST.LIB is created. The listing which follow is the code generated by GENDEF and must be assembled into the BIOS with an "include" command.

```
;
;               DISKS 7

# APPENDIX I
## PROGRAM LISTING OF INTELDSK.A86

```
;Prog Name   : INTELDSK.A86 (MDS S. Density Floppy Routines)
;Date        : 9 Aug 1982
;Written by  : Jim John, SMC 1277, 649-0592
;Modified by: Tom V. Almquist and David Stevens
;For         : Thesis (AEGIS Modeling Group)
;Advisor     : Professor M.L. Cotton
;Purpose     : This code is an include file w/in CPMBIOS.A86.
;              It contains the routines for using the MDS
;              Single Density Floppy Disk.  It is configured
;              for a single iSCB 86/12A and  does not use
;              common memory for I/O.

# APPENDIX N
# PROGRAM LISTING OF SYNC.A86

```
;Prog Name     :Synch.A86
;Date          :7 October 1982
;Written by    :Nick Hammond
;Modified by   :T. Almquist and D. Stevens
;For           :Thesis
;Advisor       :Professor Kodres
;Purpose       :Provide synchronizations of CPM/86 read
;               and write operations to the MBB-80 bubble
;               memory board and the REMEX Data Warehouse.
;
;
