SUBJ: Modified QKLOOK Program

ENCL: (1) Change 1 to JTCG/AS-79-V-008
(2) SUBROUTINE ASPTONIND

REF: (a) JTCG/AS-79-V-008

1. Recently, the four (4) QKLOOK programs, in reference (a), have been extensively modified. The modifications were made to increase the usefulness and ease of use of the QKLOOK model. The changes made (1) increase the user's control of the $P_{K/H}$ functions used in QKLOOK, (2) allow the user to select true or incremental vulnerable areas, and (3) brought the programs in line with the FORTRAN 77 standard. All the changes are thoroughly documented in enclosure (1).

2. In addition, the program VAMERGE which re-formats the QKLOOK output into a form usable by the ASALT program has now been documented. This documentation is enclosed as enclosure (2).

SECTION I

INTRODUCTION

The QKLOOK programs are a set of four FORTRAN programs which compute component, system, and total target vulnerable areas for Directed High Energy Weapons (DHEW). Vulnerable area is defined to be the product of presented area and probability of kill given a hit ($P(K/H)$) on that area. The target is described by a set of shot lines: parallel rays passed through the target, perpendicular to a specified viewing plane. These shot lines are generated from geometric target models by other computer programs such as FASTGEN or MAGIC. In addition to the shot line data, the user must supply detailed component information such as component code number, material type, density factor, initial operating temperature, and melt analysis type (melt-in-place or melt-removed), to be used in the penetration computations. The degree of component kill is determined by the depth to which the weapon is able to penetrate the component. Depths of penetration and associated $P(K/H)$'s for each critical component are specified by the user. QKLOOK then interpolates linearly between these values to determine actual component $P(K/H)$ values (and hence vulnerable areas) at times specified by the user. The weapon is described simply by its flux density, which may (but need not) vary with time. The entire target is assumed to be flood-loaded with this flux density.

The four QKLOOK programs and their specific functions are:

- CONMAG - Converts shot line encounter data produced from a MAGIC target description to the format required by QKPK. (No conversion is necessary for a FASTGEN target description).
- PRERD - Checks the input data assembled for QKPK for possible errors, and produces several summary tables of that input data.
- QKPK - Simulates penetration along each shot line and computes penetration times for each encounter with a critical component.
- PEAKAY - Computes component, system, and total target vulnerable areas at specified time intervals using the penetration times computed by program QKPK.

The vulnerable areas generated by QKLOOK can be used in vulnerability assessment and reduction studies, or as input to "end-game" computer programs where target probability of kill (P_k rather than $P(K/H)$) is determined.

ANALYST SECTIONS

Sections II, III, and IV are intended for use by the program analyst who must acquire a detailed understanding of the programs. Section II contains a set of conceptual flowcharts which provide a pictorial summary of the execution steps in the QKLOOK programs. The basic mathematical concepts employed in the QKLOOK programs are presented in Section III, the Mathematical Model. The Simulation Model, Section IV, provides a discussion of the individual FORTRAN statements in each of the QKLOOK program units. A dictionary of the FORTRAN variable names is included at the end of Section IV.

USER SECTIONS

Sections V, VI, and VII form the user portion of this manual. The information and data contained in these sections are primarily in tabular form so that they may be used as quick reference sources. Section V is used to present the formats, options, and definitions for all parameters used as input for the QKLOOK programs. The output for all of the programs is presented in Section VI. The binary output files are described in figures which list each output parameter as well as its units and definition. Each page of line printer output is also discussed and an example shown, including warning messages from the QKLOOK programs. Section VII is used to describe a sample problem. The figures for this section include copies of all formatted input and output. The sample problem is one that exercises many of the program features and user options. The user may also find the first part of Section II useful. A flowchart is given there showing the interaction of the various QKLOOK programs.

PROGRAM REQUIREMENTS/CONSTRAINTS

The largest QKLOOK program requires 22,197 (532658) words of memory on a UNIVAC 1110 computer. Peripheral requirements include one card reader, one line printer, and two mass storage devices. The programs in their present configurations have the following constraints:

1. No more than 498 components may be in the target model defined in the QKPK data deck unless array dimensions in the program are increased.
2. There must be no more than 100 encounters along any one shot line unless array dimensions in the program are increased.
3. No more than 10 systems of components may be defined unless array dimensions in the program are increased.
4. Maximum weapon intensity must be less than or equal to 60,000 watts/cm² in order for the penetration rate calculations to be valid.

FIGURE 2-5. QKLOOK: Program PRERD Conceptioal Flowchard (Page 2 of 3)

FIGURE 2-5. QKLOOK: Program PRERD Conceptual Flowchart (Page 3 of 3)

approximated by substituting the vaporization temperature for T^* in Equation 3-11:

$$\alpha F \cong k \frac{(T_v - T_m)}{Z} \quad (3-13)$$

where

T_v = the component vaporization temperature, °C

The total heat absorbed during this type of encounter is approximated by multiplying Equation 3-13 by the component area and time:

$$Q = A t k \frac{(T_v - T_m)}{Z} \quad (3-14)$$

Similarly the heat required can be approximated by replacing T^* with T_v in Equation 3-9

$$Q = A Z \rho \left[C_p (T_m - T_1) + \lambda + C_p \left(\frac{T_v - T_m}{2} \right) \right] \quad (3-15)$$

The penetration rate equation for the melt-in-place analysis when the surface temperature exceeds T_v can be obtained by equating Equations 3-14 and 3-15, and solving for the rate, R where $R = Z/t$.

$$\frac{k}{Z} (T_v - T_m) A t = A Z \rho \left[C_p (T_m - T_1) + \lambda + C_p \left(\frac{T_v - T_m}{2} \right) \right]$$

$$R = \frac{k \frac{(T_v - T_m)}{Z}}{\rho \left[C_p (T_m - T_1) + \lambda + C_p \left(\frac{T_v - T_m}{2} \right) \right]} \quad (3-16)$$

COMPONENT PROBABILITIES OF KILL

For each critical component along each shot line, penetration times are computed using the basic distance/rate equation:

$$t = \frac{d}{R} \quad (3-17)$$

where

t = the penetration time, seconds
 d = the penetration distance, meters
 R = the penetration rate, m/sec

The computed penetration times are:

t_N = the time needed to penetrate from the beginning of the shot line to the depth necessary for a non-zero component P_k equal to P_{k_N} (N is in the range from one to one less than the number of P_k values specified), seconds

t_{N+1} = the time needed to penetrate from the beginning of the shot line to the depth necessary for a component P_k equal to $P_{k_{N+1}}$ ($P_{k_{N+1}}$ is greater than or equal to P_{k_N}), seconds

t_L = the time needed to penetrate from the beginning of the shot line through the line of sight thickness of the component, seconds

The component kill probability for a time, τ , is computed as follows ($N_{\min} = 1$):

If $\tau < t_{N_{\min}}$ or $t_L < t_{N_{\min}}$ then $P_k = 0.0$

If $\tau \leq t_{N_{\min}}$ and $t_L \geq t_{N_{\min}}$ and $t_{N+1} \neq t_N$

then

$$P_k = \frac{(t_M - t_N)}{(t_{N+1} - t_N)} (P_{k_{N+1}} - P_{k_N}) + P_{k_N} \quad (3-18)$$

where

$t_M = \min(\tau, t_{N_{\max}}, t_L)$

If $\tau \geq t_{N_{\max}}$ and $t_L \geq t_{N_{\max}}$, then $P_k = P_{k_{N_{\max}}}$

COMPONENT PRESENTED AND VULNERABLE AREAS

The total presented area for a component can be computed very easily by counting the number of shot lines which intersect the component. If a shot line encounters a component one or more times, the presented area is assumed to fill the corresponding grid cell. Since there is only one shot line per grid cell, a component's presented area for one view can be expressed as:

$$A_p = N_s A_G \quad (3-19)$$

where

A_p = the total component presented area, ft^2

N_s = the number of shot lines encountering the component at least once,
nondimensional

A_G = the grid cell area, ft^2

The vulnerable area of a component is defined as the product of its presented area and its kill probability.

$$A_v = Pk_T A_p \quad (3-20)$$

where

A_v = the total component vulnerable area, ft^2

Pk_T = the total component kill probability for the view, nondimensional

Substituting Equation 3-19 for the presented area, the vulnerable area is expressed as:

$$A_V = Pk_T N_S A_G \quad (3-21)$$

In this problem, a component may be encountered in several grid cells.

Let

Pk_i = the component probability of kill for the i th shot line

Computing Pk_T as the average of the shot line kill probabilities:

$$Pk_T = \frac{\sum_{i=1}^{N_S} Pk_i}{N_S} \quad (3-22)$$

then

$$Pk_T N_S = \sum_{i=1}^{N_S} Pk_i \quad (3-23)$$

Substituting the right hand side of Equation 3-23 into Equation 3-21

$$A_V = A_G \sum_{i=1}^{N_S} Pk_i \quad (3-24)$$

A component may also be encountered more than once along a shot line. The total $P(K/H)$ for the component on the shot line is the sum of the probabilities of the exclusive events, as follows:

LIST OF ABBREVIATIONS AND SYMBOLS
(MATHEMATICAL MODEL)

Abbreviation or symbol	Equivalent in Simulation Model	Definition	Units
N_S	---	Number of shot lines encountering a component	---
N	---	Number of encounters for a component on the j th shot line	---
Pe_i	PK	Probability of kill for the i th encounter and no kill on a previous encounter	---
P_i	PK	Component probability of kill on the i th encounter	---
Pk_j	---	Component probability of kill from one shot line	---
Pk_T	---	Average of the probabili- ties of kill for all shot lines	---
Q	---	Heat absorbed by the component	joules
R	RATE	Penetration rate of a Directed High Energy Weapon against a component	m/sec
t	---	Penetration time (in Com- ponent Probabilities of Kill subsection); time duration of an encounter (in Penetration Rates subsection)	seconds
T^*	TSTAR	Component outer surface temperature	$^{\circ}\text{C}$
T_1	TINIT	Component initial operating temperature	$^{\circ}\text{C}$

LIST OF ABBREVIATIONS AND SYMBOLS
(MATHEMATICAL MODEL)

Abbreviation	Equivalent in Simulation Model	Definition	Units
T_m	TMLT	Component melting temperature	$^{\circ}\text{C}$
T_v	TVAP	Component vaporization temperature	$^{\circ}\text{C}$
t_L	PLS	Time required to penetrate from the beginning of a shot line to the depth necessary to perforate the component	seconds
t_M	PK3	Time needed to achieve the maximum Pk for a component in a time interval	seconds
t_N	PKTIME	Time required to penetrate from the beginning of a shot line to the depth associated with a Pk equal to Pk_N	seconds
Pk_N	PKVAL	Pk associated with penetration to a specified depth	---
Z	DP	Component actual line of sight thickness	meters
α	ALP	Component coupling coefficient, absorption factor	---
ΔE_{T_m}	---	Energy per unit mass needed to raise the temperature from T_1 to T_m	joules/kgm

SUBROUTINE BSRCH

This subroutine is used to find the link between a component number for an encounter and the component information arrays. This is done by executing a binary search of the component number array, ICOMP, which was sorted into ascending order in Subroutine FSORT. If the binary search can find no link, a default link is assigned.

The first set of statements

```
SUBROUTINE BSRCH(ICOMP,NOCOMP,ITC)
COMMON /PROP/ ALP,HHU,CP,TMLT,ALAMBD,RATE,JCOMP,J,UP,XK,TVAP,
$          CPL,ITEN,T
COMMON /LUNITS/ IND,IWR,IIN,IOUT
DIMENSION ICOMP(ITC)
```

is used to pass three arguments, ICOMP, NOCOMP, and ITC to this subroutine. ICOMP is the array being searched; NOCOMP is the number of values in this array; and ITC is the dimension of ICOMP. The statements are also used to specify two named commons which are used to transfer information into and out of this subroutine. In COMMON /PROP/, the variable JCOMP is the component number to be matched and the variable J is the subscript of the matching element in array ICOMP. The DIMENSION statement is used to declare the argument ICOMP to be an array.

The statements

```
IBEG = 0
IEND = NOCOMP + 1
10 CONTINUE
J = (IBEG + IEND) / 2
IF (J .NE. IBEG) THEN
  IF (ICOMP(J) .LT. JCOMP) THEN
    IBEG = J
  ELSE IF (ICOMP(J) .GT. JCOMP) THEN
    IEND = J
  END IF
ELSE
```

are used to perform the binary search. The algorithm begins by setting a pointer, IBEG, at the beginning of the array and another pointer, IEND, at the end of the array. An iterative procedure is used to set a third pointer, J, halfway between IBEG and IEND and to compare the Jth element with the desired value, JCOMP. The first block IF statement is false only if no match for JCOMP exists in the array ICOMP. In this case, the ELSE branch is executed. In all other cases, the block IF in the THEN branch is executed to compare the values JCOMP and ICOMP(J). If JCOMP is larger, the beginning pointer, IBEG, is moved to position J. If JCOMP is smaller, the end pointer, IEND, is moved to J. If the values are equal, the algorithm is finished.

The following statements

```
IF (JCOMP .LT. 1000) THEN
  J = ITC - 1
ELSE IF ((JCOMP .GE. 7000) .AND. (JCOMP .LE. 7999)) THEN
  J = ITC
ELSE
  WRITE (IWR,100) JCOMP
  J = ITC
END IF
RETURN
END IF
```

```

      IF (ICOMP(J) .NE. JCOMP) GO TO 10
      RETURN
100 FORMAT (1X,110,' WAS NOT FOUND IN LIST...DEFAULT TO 7075 AL')
      END

```

are used to allow a component number, JCOMP, to use default characteristics; i.e., the formatted input for the component information arrays does not need to include every component in all shot line encounters. An encounter component JCOMP with a number less than 1,000 and no match in the ICOMP array is assigned default data for a 2024 AL component. These default data for this type of component are stored at location ITC-1 in the component information arrays. Similarly, a component number JCOMP between the numbers 7000 and 7900 with no match in the ICOMP array is assigned default data (stored at location ITC in the component information array) for a 7075 AL component. If a component number, JCOMP, is in neither of the above ranges and has no match in the array ICOMP, the subroutine causes a warning message to be written. At this point, the default link ITC (7075 AL) is assigned. Control is then returned to the calling routine. The two END IF statements close the block IF statement assigning the default characteristics and the block IF checking whether a match for JCOMP may yet exist in the array ICOMP. If the algorithm has not yet completed, the GO TO statement branches to Statement 10 for another iteration.

are used to conclude the binary output file in QKLOOK format by writing a final binary record with the values of XX (= 999.0). The binary file is then rewound and the first record is overwritten. The new initial record is identical to the original one except that it includes the minimum and maximum coordinate values of all shot lines on the viewing plane. The purpose of the new initial record is to facilitate the use of a plotting program which would require the minimum and maximum values for scaling before the data can be plotted. Finally, the binary file on device IOUT is rewound in preparation for a run of Program QKPK.

The last set of statements

```

```

is used to define all formats used for input and output within the program and to indicate the end of this program.

SUBROUTINE FSORT

This subroutine is invoked by two programs in the QKLOOK set, Programs PRERD and QKPK. It is used to sort the component information arrays into ascending order by component number. ICOMP is the array of component numbers and is the basis for the sorting process while NOCOMP is the number of components in the array ICOMP. With the exception of ITC and PKNBR, which are used to dimension the passed arrays, the remaining arguments are other component information arrays. These information arrays correspond to the component number array by subscripts; therefore, a switch in this routine will require switches in each of the 12 corresponding arrays. Subroutine FSORT is used to perform a diminishing increment sort which requires a large number of comparisons but a relatively small number of switches, making this algorithm very efficient for this type of problem.

The first set of statements

```

SUBROUTINE FSORT(ICOMP, NOCOMP, MAT, IFG, ITAB, IANA, TINIT, NOPNTS,
$              DEPTH, PKVAL, ITC, PKNBR, THINFL, RHOF, IY, IU)
$  INTEGER IANA (ITC),
$  ICOMP (ITC),
$  IFG (ITC),
$  ITAB (ITC),
$  IU (ITC),
$  IY (ITC),
$  MAT (ITC),
$  NOPNTS (ITC),
$  PKNBR
$  REAL BUFFN1(50),
$  BUFFN2(50),
$  DEPTH (PKNBR, ITC),
$  PKVAL (PKNBR, ITC),
$  RHOF (ITC),
$  THINFL (ITC),
$  TINIT (ITC)

```

is used to transfer 16 arguments to and from the calling programs, and to declare 13 of these arguments to be arrays.

The statements

```

      M = NOCOMP
10  CONTINUE
      M = M / 2
      IF (M .LT. 1) GO TO 50

```

are used to compute and test the increment size M. Initially, M is half of the array length. After each of the M sublists is sorted, the routine returns to Statement 10. The increment size M is halved again and the sublist is sorted. The final sort is executed when M equals 1; then, the above IF statement causes a branch to Statement 50, the end of the subroutine.

The next statements

```

      K = NOCOMP - M
      DO 40 J = 1, K

```

are used to compute K, the number of steps required to sort the M sublists, and to initiate the execution of a DO loop for every step.

The statements

```

      I = J
20    CONTINUE
      IM = I + M
      IF (ICOMP(I) .LE. ICOMP(IM)) GO TO 40

```

are used to perform a comparison between two elements in a sublist. The computation for IM is used to indicate that each sublist consists of all array elements at intervals equal to the increment size M. If the comparison shows that these two elements are already in ascending order, the routine branches to Statement 40, the end of the DO loop; otherwise, the two array elements and all corresponding array elements must be interchanged.

These statements

```

      NO = ICOMP(I)
      N1 = MAT(I)
      N2 = IFG(I)
      N3 = ITAB(I)
      N4 = IANA(I)
      N5 = IY(I)
      N6 = IU(I)
      N7 = NOPNTS(I)
      S1 = TINIT(I)
      DO 30 MM = 1, PKNBK
        BUFFER1(MM) = DEPTH(MM, I)
        BUFFER2(MM) = PKVAL(MM, I)
30    CONTINUE
      S4 = THINFL(I)
      S5 = RHOF(I)
      ICOMP(I) = ICOMP(IM)
      MAT(I) = MAT(IM)
      IFG(I) = IFG(IM)
      ITAB(I) = ITAB(IM)
      IANA(I) = IANA(IM)
      IY(I) = IY(IM)
      IU(I) = IU(IM)

      NOPNTS(I) = NOPNTS(IM)
      TINIT(I) = TINIT(IM)
      DO 34 MM = 1, PKNBK
        DEPTH(MM, I) = DEPTH(MM, IM)
        PKVAL(MM, I) = PKVAL(MM, IM)
34    CONTINUE
      THINFL(I) = THINFL(IM)
      RHOF(I) = RHOF(IM)
      ICOMP(IM) = NO
      MAT(IM) = N1
      IFG(IM) = N2
      ITAB(IM) = N3
      IANA(IM) = N4
      IY(IM) = N5
      IU(IM) = N6
      NOPNTS(IM) = N7
      TINIT(IM) = S1
      DO 38 MM = 1, PKNBK
        DEPTH(MM, IM) = BUFFER1(MM)
        PKVAL(MM, IM) = BUFFER2(MM)
38    CONTINUE
      THINFL(IM) = S4
      RHOF(IM) = S5

```

are used to switch the two compared elements along with all elements from the 12 other arrays corresponding to them.

The statements

```

      I = I - M
      IF (I .GE. 1) GO TO 20

```

are used to finish the sort of the sublist. After the switch of two sublist elements in the previous step, I is decremented to the next element lower in the sublist. The IF statent is used to branch back to Statement 20 where the two lower elements of the sublist are sorted. The IF statement does not branch back when I is already at the bottom of the sublist.

The statements

```

40  CONTINUE
    GO TO 10

```

are used to end the DO loop and cause a branch to Statement 10. The DO loop is completed when all of the M sublists are sorted. The branch to Statement 10 is used to halve the increment size and repeat the above steps.

The statements

```

50  CONTINUE
    RETURN
    END

```

are executed only after the increment size M is less than one, which means that the array ICOMP has been sorted into one sublist. These statements are used to return control to the calling subroutine and to end this program unit.

PROGRAM PEAKAY

This program is the fourth in the series of QKLOOK programs. It is used to compute component, system, and total target kill probabilities and vulnerable areas. The encounter penetration times, which are read from the binary file generated by Program QKPK, are used to compute the kill probabilities in Subroutine PENT, the only subroutine in this program. After the component and system Pk's are known, the vulnerable area computations are done in Program PEAKAY with the assumption that the presented area for each encounter equals the grid size. The printed output includes presented areas and vulnerable areas for individual components, systems of components, and total target. These data can be computed for up to 10 time intervals specified by the user in the formatted input. A greater number of time intervals may be obtained by using multiple runs with the same binary input file. A copy of all input, the shot line Pk's, and the formatted output are also produced on four binary output files.

The first group of statements

```

INTEGER  AVFLAG
COMMON  NI(10,200),NS(200),II(200),PRTIME(10,100),

```

represent DATA statements, which are used to initialize several variables. The variables in the first DATA statement are the input and output device numbers. The last three DATA statements are used to initialize the dimension

of the component arrays, ITC, the percent of vulnerable area, PCV, and a factor for conversion from square feet to square meters, SQFSQM. The rest of the variables in the DATA statements are initialized equal to 0.00

The statements

```
OPEN (IRD,FILE='PKDATA',RECFM='DS',MAXRECL=80,PAD='YES')
OPEN (IINR,FILE='PKPRINT',RECFM='DS',CARRIAGE CONTROL='FORTRAN')
OPEN (IIN,FILE='QKPKTAPEOUT',FORM='UNFORMATTED',RECFM='VARIABLE')
OPEN (IOUT1,FILE='PKTAPEOUT1',FORM='UNFORMATTED',RECFM='VARIABLE')
OPEN (IOUT2,FILE='PKTAPEOUT2',FORM='UNFORMATTED',RECFM='VARIABLE')
OPEN (IOUT3,FILE='PKTAPEOUT3',FORM='UNFORMATTED',RECFM='VARIABLE')
OPEN (IOUT4,FILE='PKTAPEOUT4',FORM='UNFORMATTED',RECFM='VARIABLE')
```

are used to connect logical units to the input and output files and to establish the connection properties between each unit/file pair.

The statements

```
REWIND IIN
READ (IRD,1003) NTIME,AVFLAG
READ (IRD,1001) (TIMES(J),J=1,NTIME)
READ (IIN) AZ,EL,GRID,DOVEH,YMAX,YMIN,ZMAX,ZMIN,NUCOMP
READ (IIN) (ICOMP(I),IFG(I),IY(I),IU(I),NOPNTS(I),
$ (PKVAL(J,I),J=1,NUPNTS(I)),I=1,NUCOMP),IRVRS,IFMAX,
$ (FTIM(I),FXCM(I),I=1,IFMAX)
```

are used to read the formatted input file and the first two records of the binary file from Program QKPK. The REWIND statement is used insure that the first binary read will start at the file origin. The two formatted READ statements are used to read the number of time intervals, the flag determining whether component vulnerabilities are to be calculated as true or as incremental, and the times for each interval. This is the only formatted input required for this program. The two binary READ statements are used to read the first two records of the binary input file. These data include the viewing grid description, the component information arrays, and the flux distribution table.

The next statements

```
IF (ITC .GE. NUCOMP*2) THEN
  WRITE (IINR,4) NTIME,(TIMES(J),J=1,NTIME)
  RVRS = IRVRS
  WRITE (IINR,8) RVRS
  WRITE (IINR,800) IFMAX
  TE = 0.
  DO 820 I = 1,IFMAX
    Tb = TE
    TE = FTIM(I)
    WRITE (IINR,810) Tb,TE,FXCM(I)
820 CONTINUE
  Id = TE
  Te = 1.E30
  WRITE (IINR,810) Id,Te,FXCM(IFMAX)
```

are used to test the number of components and print the first page of formatted output. The block IF statement is used to insure that the number of components does not exceed array dimensions. If this fatal error occurs, the program will execute the ELSE branch of the block IF. Note that Program QKPK also tests and aborts on the same error. The first WRITE statement is used to print the number of time intervals and the time values for which Pk's and vulnerable areas will be computed. This is followed by two WRITE statements that are used to print the reverse flag and the number of points in the flux distribution. The

rest of the statements are used to print the flux distribution table. The DO loop is used to print flux array values with corresponding begin times and end times. The final WRITE statement is used to print the final line of the flux table indicating that the last flux level applies to all times greater than the last end time.

The statements

```

WRITE (IOUT1) AZ,EL,GRID,IUVEH,YMAX,YMIN,ZMAX,ZMIN,NOCOMP
WRITE (IOUT1) (ICOMP(I),IFG(I),IY(I),IU(I),I=1,NOCOMP),IRVRS,
5 IFMAX,(FTIM(I),FXCH(I),I=1,IFMAX)
10 CONTINUE
   READ (IIN) ((R1(I,J),I=1,10),R3(J),I1(J),J=1,200)
   WRITE (IOUT1) ((R1(I,J),I=1,10),R3(J),I1(J),J=1,200)
   IF (I1(200) .NE. 9999) GO TO 10

```

are used to save a copy of the binary input data from Program QKPK on the first binary output file. The first two binary WRITE statements are used to write the data from the first two records of binary input. The statements following Statement 10 are used to iteratively read and then write the binary records. The IF statement is used to test for the end of view flag and to continue to loop until the last binary record has been echoed. Note that data written on device IOUT1 are in the identical order as data on device IIN.

The statements

```

END FILE IOUT1
REWIND IIN
GRID = GRID * GRID / 144.

```

are used to place an end of file mark on the first binary output file, to rewind the binary input file, and to convert the variable GRID from a length to an area expressed in square feet.

The statements

```

HEAD (IIN)
HEAD (IIN)
MAXTIM = NTIME + 2

```

are used to skip the first two records of the binary input file and compute the variable MAXTIM, which is a dimension size for the SHW array. By using the two binary READ statements to pass two records, the binary input file is now at the start of the shot line penetration times computed by Program QKPK.

The statements

```

100 CONTINUE
   READ (IIN) ((R1(I,J),I=1,10),R3(J),I1(J),J=1,200)
   DO 110 J = 1,200
     IF (I1(J) .EQ. 9999) GO TO 5000

```

are the starting point for the time file processing loop. The binary READ is used to read and store one binary record which fills three arrays. The DO statement is used to initiate a DO loop which iterates 200 times to process each set of array elements. The IF statement is used to branch out of the time file processing loop when an end of view flag is detected. Since the

end of the DO loop is followed by the statement GO TO 100, Statement 100 is used as a return point so that another record of binary input may be read and processed.

The statements

```

IF (IST .LE. 0) THEN
  ITOTL = ITOTL + 1
  NENC = I1(J)
  NSHT = NSHT + 1
  SHW(1,NSHT) = R1(1,J)
  SHW(2,NSHT) = R1(2,J)
  IF (NENC .NE. 0) THEN
    IST = NSHT
    NUM = 0

```

are used to store the initial data for each new shot line on the viewing plane. The block IF statement is used to test the shot line index, IST. The index IST equals 0 when a new shot line is being defined. When the IF statement detects a new shot line, the preceding statements are used. The variable ITOTL, which counts the number of shot lines in the view, is incremented by using the first assignment statement. The number of encounters on the shot line is assigned to NENC and the subscript NSHT is incremented by using the next two assignment statements. The first two rows of the array SHW are used to store shot line coordinates on the viewing plane. The second block IF statement checks if there is at least one critical encounter on the shot line. If so, the next two statements are executed to assign the shot line numbers to IST and to initialize the subscript NUM.

The statements

```

ELSE
  DO 112 MM = 3, MAXTIM
    SHW(MM,NSHT) = -9.
112  CONTINUE
END IF

```

are executed only when a shot line has no critical encounters. The DO loop is used to fill the rest of the SHW array with the value -9.0, designated as a flag to indicate no critical encounters. The END IF statement closes the block IF.

The statements

```

ELSE
  NUM = NUM + 1
  DO 114 K = 1,10
    PKTIME(K,NUM) = R1(K,J)
114  CONTINUE
    PLS(NUM) = R3(J)
    NAME(NUM) = I1(J)

```

can be executed only when processing a set of binary input data that contains penetration times for an encounter (i.e., not the start of a new shot line). The first assignment statement is used to increment the variable NUM and the remaining assignment statements are used to store the eleven penetration times as well as the component number location in the PKTIME, PLS, and NAME arrays, indexed by the encounter number NUM.

The next statements

```

      IF (NUM .GE. NENC) THEN
      DO 115 I = 1,10
        ISET(I) = 0
115      CONTINUE
      DO 116 I = 1,NENC
        II = NAME(I)
        LL = IY(II)
        IF (LL .NE. 0) ISET(LL) = 1
        IF (I .NE. NENC) THEN
          DO 116 13 = 1+1,NENC
            IF (II .EQ. NAME(13)) GO TO 118
116          CONTINUE
        END IF
        PAREA(II) = PAREA(II) + 1.
118      CONTINUE

```

are executed only after the data for every encounter on a shot line have been stored. The first DO loop is used to assign zeros to the system encounter array ISET. This is followed by a DO loop which is used to increment the presented area array PAREA for each component on this shot line and to assign a one to the ISET array for every system represented on this shot line. The first two assignment statements in the loop are used to assign the component location to II and the system number to LL. The logical IF statement is used to allocate a one to the ISET array if the encountered component is in a system. The last assignment statement in the loop is used to increment the PAREA array for the encountered component. The block IF with its DO loop is used to insure that the presented area for a component is incremented only once even if the component is in more than one encounter on a shot line.

The statements

```

      DO 119 I = 1,10
        SAREA(I) = SAREA(I) + ISET(I)
119      CONTINUE

```

are used to accumulate the number of shot lines that encounter each system into the SAREA array. When all shot lines for a view have been processed, the SAREA array contains the number of shot lines that have an encounter with a component in each system.

The next statements

```

      CALL PENT
      IST = 0

```

are used to invoke Subroutine PENT and reset the shot line index IST. Subroutine PENT is used to perform the shot line penetration computations for component, system, and total shot line kill probabilities at the time intervals specified by the user's formatted input. These data are transferred using the common storage areas.

The statements

```

      DO 107 II = 1,NTIME
        TVA(II) = TVA(II) + SHW(II+2,NSHT)
107      CONTINUE

```

are used to store the cumulative kill probabilities for all time intervals. After all shot lines have been processed, the array TVA contains the cumulative kill probabilities for a shot line at each time interval from the first to the NTIME intervals. These data are used later to compute the total target vulnerable area at each time interval by multiplying the kill probability by the presented area.

The next statements

```

        END IF
      END IF
      IF (NSMT .EQ. 200) THEN
        WRITE (IOUT2) ((SHW(I1,MM),I1=1,12),MM=1,200)
        NSMT=0
      END IF
110    CONTINUE
      GO TO 100

```

are used to end the time file processing loop. The first END IF statement closes the IF block used when all encounters on a shot line have been processed. The second END IF closes the IF block that tests whether a new shot line is being defined. The block IF statement is used to execute the binary WRITE statement when the SHW array has data from 200 shot lines. The execution of the binary WRITE statement is followed by an assignment statement which is used to reset NSMT, the number of shot lines in array SHW, to zero. If the array is not full, the block IF is bypassed and execution continues at Statement 110. This statement is used to end the time file processing DO loop. After the DO loop has been executed for each of the 200 elements in the binary input arrays, the GO TO statement is used to return to Statement 100 to read and process a new set of binary input.

The statements

```

5000  CONTINUE
      NSMT = NSMT + 1
      DO 5010 K = 3,MAXTIM
        SHW(K,NSMT) = -9999.
      5010 CONTINUE
      WRITE (IOUT2) ((SHW(I1,MM),I1=1,12),MM=1,200)
      END FILE IOUT2

```

are executed only after the time file processing loop has detected the end of view flag. The assignment statement and DO loop are used to assign an end of view flag equal to -9999.0 in the next row of the SHW array. The binary WRITE statement is used to send the last set of shot line Pk data to the binary file on device IOUT2. The ENDFILE statement is used to put an end of file mark on the binary output file.

The statements

```

      WRITE (IHW,7001) PCV
      JQW = 0
      PKV = PCV * 0.01

```

are used to begin the next page of PEAKAY printed output. Execution of the WRITE statement prints the heading for the page of output containing the time intervals during which the vulnerable areas reach 90 percent of the presented area. The two assignment statements are used to initialize the counter JQW and to convert the required percent of vulnerable area PCV to decimal form. (The

value of 90 percent for the variable PCV is assigned in a DATA statement. If another percentage is desired, a change of value in the DATA statement is the only action required).

The next statements

```
DO 8000 MU = 1, NOCOMP
  IF (IFG(MQ) .NE. 0) THEN
    IF (PRNT(3, MQ) .LE. 0.) THEN
      JQQ = JQQ + 1
      PKNK(JQQ) = ICUMP(MQ)
    END IF
```

are used to begin a loop which determines the time interval during which each component's vulnerable area reaches 90 percent of its presented area. The DO statement is used to initiate the loop which iterates for every component. The first block IF statement is used to exclude noncritical components from this summary by passing control to the end of the loop if the component's criticality flag is not set. The second block IF statement is used to determine the components which have a zero probability of kill by testing the third row of the PRNT array. The statements in the IF block are used to count and save the component numbers for components which have a zero probability of kill. The variable JQQ is used to count these components, and their component numbers are saved in array PKNK.

The statements

```
IF (PAEA(MQ) .GT. 0.) THEN
  DO 6010 K = 1, NTIME
    IF (COMPAV(MQ, K) / PAEA(MQ) .GE. FHV) THEN
      IF (K .GT. 1) THEN
        TB = TIMES(K-1)
      ELSE
        TB = 0
      END IF
      WRITE (IWM, 7002) ICUMP(MQ), (PRNT(JJ, MU), JJ=1, 4), TB,
        TIMES(K)
      GO TO 8000
    END IF
  CONTINUE
6010  END IF
      WRITE (IWM, 7002) ICUMP(MQ), (PRNT(JJ, MU), JJ=1, 4)
    END IF
8000  CONTINUE
```

are used to select the time interval for which each component's vulnerable area reaches 90 percent of its presented area and to print that information. The first IF block is used to bypass components with no presented area; i.e., no shot line has an encounter with the component. For components with a presented area, the DO loop is used to test the component vulnerable area at each time interval. The next IF block is used only for components whose vulnerable area reaches 90 percent. The block contains another IF block to determine the time interval during which the vulnerable area reached 90 percent of the presented area. The WRITE statement prints component encounter information contained in the PRNT array as well as the time interval previously determined. The GO TO statement then branches to the end of the component loop. The END IF statement following Statement 6010 closes the IF block for components having a presented area. The following WRITE statement is executed for components whose vulnerable area does not reach 90 percent of the presented area as well as for those which have no presented area. Statement 8000 is used

to end the DO loop executed for every component.

The next statements

```

      DO 305 J = 1, NOCOMP
        PAREA(J) = PAREA(J) * GRID
        DO 300 K = 1, NTIME
          COMPAV(J,K) = CUMPAV(J,K) * GRID
300    CONTINUE
305  CONTINUE

```

use two nested DO loops to compute component presented and vulnerable areas. The presented area, A_p , is computed using the expression:

$$A_p = N_S A_G \quad (3-19)$$

The vulnerable area is computed using the expression:

$$A_v = A_G \sum_{i=1}^{N_S} Pk_i \quad (3-20)$$

The sum of shot line Pk's was computed in Subroutine PENT and stored in the COMPAV array. The outer DO loop is used to iterate for every component and the inner loop is used to iterate for every time interval.

The statements

```

      DO 315 K = 1, NTIME
        TVA(K) = TVA(K) * GRID
        TVAM(K) = TVA(K) * SDFSUM
        DO 310 J = 1, 10
          PMULT(J,K) = PMULT(J,K) * GRID
310    CONTINUE
315  CONTINUE

```

are used to convert the total target and system kill probabilities to vulnerable areas. The outer DO loop is used to iterate for each time interval. The first assignment statement is used to compute the total vulnerable area as the product of the total Pk and the specified grid area. The second assignment statement is used to compute the total vulnerable area in square meters and store it in the TVAM array. The inner DO loop is used to iterate for each of 10 possible systems. The last assignment statement is used to compute the system vulnerable area by multiplying the system Pk and the grid area expressed in square feet.

The statements

```

      IF (AVFLAG .EQ. 1) THEN
        WRITE (IWR,1004) (TIMES(K),K=1,NTIME)
      ELSE
        WRITE (IWR,1007) (TIMES(K),K=1,NTIME)
      END IF
      WRITE (IOUT3) AZ,EL,IFMAX,(FTIM(I),FXCM(I),I=1,IFMAX),NVRS,
      NOCOMP,NTIME,(TIMES(I),I=1,NTIME)

```

```

DO 320 J = 1, NOCOMP
  IF (IFG(J) .NE. 0) THEN
    WRITE (IAH,1005) ICOMP(J), PAREA(J), (COMPAV(J,K), K=1, NTIME)
    WRITE (IOUT3) ICOMP(J), PAREA(J), (COMPAV(J,K), K=1, NTIME)
  END IF
320 CONTINUE
END FILE IOUT3
TOTL = ITOTL*GRID
WRITE (IAH,7005) TOTL, ITOTL
WRITE (IAH,7006) (TVA(K), K=1, NTIME)

```

are used to write the third page of PEAKAY printed output and the third binary file. The first IF block is used to print the page heading and time increments, depending on whether true component vulnerabilities (AVFLAG = 1) or incremental component vulnerabilities (AVFLAG = 0) are calculated. The first binary WRITE statement is used to write the attack angles, the flux table, the reverse flag, the number of components, and the time intervals on the binary output file. The DO loop is used to print the component number, the presented area, and the vulnerable area at each time increment for every critical component. Two WRITE statements are used to write these data on both output devices. The IF block is used to bypass the WRITE statements for noncritical components. The ENDFILE statement is used to write an end of file after the third binary file. The assignment statement is used to compute the total target presented area as the product of the total number of shot lines and the grid size. The last two formatted WRITE statements are used to print the total presented area, the total number of shot lines, and the total target vulnerable area at each time increment.

The next statements

```

WRITE (IAH,1008) (TIMES(K), K=1, NTIME)
DO 325 K = 1, 10
  SAREA(K) = SAHEA(K) * GRID
  WRITE (IOUT4) SAREA(K), K, (PMULT(K,J), J=1, NTIME)
  WRITE (IAH,1005) K, SAHEA(K), (PMULT(K,J), J=1, NTIME)
325 CONTINUE

```

are used to start the fourth binary output file and to print the fourth page of PEAKAY formatted output. The first WRITE statement is used to print the heading and time increments for the new page of formatted output. The DO loop is executed for each of ten possible systems. The assignment statement is used to compute the system presented area by multiplying the number of shot lines by the grid area. This is followed by two WRITE statements which write the system number, system presented area, and the system vulnerable area for each time increment on both output devices. If a system number is not used in the target model, the system number is printed with 0.0 values for the presented and vulnerable areas. It should be noted that a multiply vulnerable component does not contribute to any system vulnerable area.

Execution of the binary WRITE statement

```

WRITE (IOUT4) J00, (PKNK(NCN), NCN=1, J00)

```

records the component number of any component with a kill probability equal to zero on the fourth binary output file.

The next group of statements

```

      DO 360 J = 1, NUCOMP
        PAREA(J) = PAREA(J) * SQFSQM
        DO 350 K = 1, NTIME
          CUMPAV(J,K) = CUMPAV(J,K) * SQFSQM
350      CONTINUE
360      CONTINUE
      IF (AVFLAG .EQ. 1) THEN
        WRITE (IWR,1006) (TIMES(K),K=1,NTIME)
      ELSE
        WRITE (IWR,1011) (TIMES(K),K=1,NTIME)
      END IF
      DO 370 J = 1, NUCOMP
        IF (IFG(J) .NE. 0)
          WRITE (IWR,1005) ICUMP(J), PAREA(J), (CUMPAV(J,K), K=1, NTIME)
370      CONTINUE
      TOTL = TOTL * SQFSQM
      WRITE (IWR,7007) TOTL, ITOTL
      WRITE (IWR,7008) (TVAM(K), K=1, NTIME)

```

is used to print component presented area and vulnerable area table values expressed in square meters. The first two nested DO loops are used to convert the presented areas and the vulnerable areas from square feet to square meters for every component and every time increment. The IF block prints the page heading and time increments, depending on whether true component vulnerabilities (AVFLAG = 1) or incremental component vulnerabilities (AVFLAG = 0) are calculated. The second DO loop is used to print the presented area and vulnerable area tables for all critical components. Noncritical components are excluded from the table by using the IF statement inside the loop. The last three statements are used to convert the total presented area to square meters and to print the total target vulnerable areas.

Then the statements

```

      WRITE (IWR,1009) (TIMES(K),K=1,NTIME)
      DO 400 K = 1, 10
        SAREA(K) = SAREA(K) * SQFSQM
        DO 380 J = 1, NTIME
          PMULT(K,J) = PMULT(K,J) * SQFSQM
380      CONTINUE
        WRITE (IOUT4) SAREA(K), K, (PMULT(K,J), J=1, NTIME)
        WRITE (IWR,1005) K, SAREA(K), (PMULT(K,J), J=1, NTIME)
400      CONTINUE

```

are used to form two nested DO loops used to print the system presented area and vulnerable area tables after converting all values to square meters. The outer DO loop is used to iterate for each of the ten possible systems. After the system presented area is converted, the inner loop is used to convert the system vulnerable areas at each time increment. The last two WRITE statements each contain an implied DO loop, and are used to write the system number, presented area, and vulnerable area at each time increment. Statement 400 is used to end the system DO loop. These statements are used to write a record on each output device for the 10 system numbers. If a system number is not used in the target model, a record is printed with zeros for the presented and vulnerable areas.

The statements

```

      WRITE (IWR,7011)
      DO 330 J = 1, NUCOMP
        IF ((IFG(J) .NE. 0) .AND. (PAREA(J) .LE. 0.))
          WRITE (IWR,7012) ICUMP(J)
330      CONTINUE

```

330 CONTINUE

are used to print the seventh page of PEAKAY formatted output which consists of a list of critical components whose presented areas equal zero. The first WRITE statement is used to print the page heading. The DO loop is used to iterate for every component. The IF statement is used to print the component number for critical components with zero presented area. Other components are bypassed.

The next set of statements

```

WRITE (IWR,7013)
DO 340 J = 1,NOCOMP
  IF ((IFG(J) .NE. 0) .AND. (PRNT(3,J) .LE. 0.)) THEN
    ASQF = PAKEA(J)/SWFSUM
    WRITE (IWR,1010) ICUMP(J),ASQF,PAKEA(J)
  END IF
340 CONTINUE

```

is used to print the last page of formatted output, a list of critical components with zero vulnerable area. The first WRITE statement is used to print the page heading. The DO statement is used to initiate a loop to check every component. The IF block checks for critical components whose vulnerable area is zero. For those components, the presented area is converted back to square feet by executing the assignment statement. The last WRITE statement is used to print the component number, and the presented area expressed in both square feet and square meters for any component with zero vulnerable area.

The statement

```

WRITE (IOUT4) (TVA(I),TVAM(I),I=1,NTIME)

```

is used to write the total target vulnerable areas in square feet and square meters at each time increment on the last binary output record.

The statements

```

ELSE
  WRITE (IWR,7014)
END IF
STOP

```

are the final executable statements in the program. The ELSE branch of the block IF is executed only if the number of components is too large for the array dimensions. The write statement is used to print a fatal error message on the formatted output file, and the STOP statement is used to halt program execution. Program QKPK tests and aborts on this same error.

```

is used to define the input/output formats needed for program execution.
This group of statements concludes Program PEAKAY.

SUBROUTINE PENT

This subroutine is called by Program PEAKAY for every shot line on the viewing plane and is used to compute the shot line penetration. Two nested DO loops are used to proceed along the shot line encounters at the time intervals specified by the user in the formatted PEAKAY input. The penetration times from the PEAKAY binary input file are used to compute component kill probabilities at each time interval. The component Pk's are used to compute system Pk's, total shot line Pk's, and cumulative Pk's for each component.

The statements

```

SUMM TIME PENT
INTEGER AVFLAG
DIMENSION PKC(100),PKS(10)
COMMON  N1(10,200),N3(200),I1(200),PKTIME(10,100),
$        PKVAL(10,100),NOMPLS(500),PLS(100),
$        LUC(100),IST,NSMT,NENC,ICOMP(500),SHW(12,200),
$        NUCOMP,COMPAV(500,10),GRID,TIMES(10),NTIME,IY(500),
$        PMULT(10,10),IU(500),MAREA(500)
COMMON  /UNE/ IFG(500),PMNT(4,500),AVFLAG
LOGICAL SNGSYS,MULSYS,IXSET

```

are used to declare array dimensions, provide for transfer of data into and out of this subroutine via common storage areas, and to declare the variable AVFLAG to be integer and the variables SNGSYS, MULSYS, and IXSET to be logical.

The statements

```

PMX = 0.
TBEG = 0.
NEND = 1
DO 10 II=1,10
    PKS(II) = 0.
10 CONTINUE

```

are used to initialize the variables PMX, TBEG, NEND, and the PKS array.

The next statements

```

DO 6000 NTIM=1,NTIME
    TEND = TIMES(NTIM)
    NBEG = NEND

```

are used to begin the time penetration loop. This DO loop is executed for every time interval specified in the user card input. Execution of the first assignment statement results in the assignation of the end time for this interval to the variable TEND. Execution of the other assignment statement results in the value of NBEG being set equal to the last encounter number that was not breached during a previous time interval.

The statements

```

DO 1000 II=NBEG,NENC
    NEND = II
    PK = 0.
    PKC(II) = 0.
    SPK = 0.
    I = LOC(II)
    L = IY(I)

```

are used to start a DO loop which iterates for each encounter remaining on the shot line. The first assignment statement is used to transfer the encounter number for the iteration to the variable NEND. The next three assignment statements are used to assign initial values of 0.0 to the variables PK, PKC(II), and SPK. The last two assignment statements are used to assign the component number location to I and the system number to L.

The next two statements

```
SNGSYS = (L .NE. 0) .AND. (IU(I) .EQ. 0)
MULSYS = (L .NE. 0) .AND. (IU(I) .EQ. 1)
```

are used to assign values to two logical variables. The singly vulnerable system flag, SNGSYS, is assigned a value of TRUE only if the encountered component is in a system and its multiply vulnerable flag, IU, is 0. The multiply vulnerable system flag, MULSYS, is assigned a value of TRUE only if the encountered component is in a system and its multiply vulnerable flag is set to a value of 1.

The statements

```
IF (TEND .LT. PKTIME(1,II)) GO TO 1900
IF (PLS(II) .GE. PKTIME(1,II)) THEN
  IF (PKVAL(NOPNTS(1),I) .EQ. 1.0) THEN
    PK1 = AMIN1(PKTIME(NUPNTS(1),II),PLS(II))
  ELSE
    PK1 = PLS(II)
  END IF
  IF (TBEG .LT. PK1) THEN
    IX = 1
    IXSET = .FALSE.
    CONTINUE
    IF ((IX .LT. NOPNTS(1)) .AND.
      (PKTIME(IX,II) .LT. TEND)) THEN
      IX = IX + 1
    ELSE
      IXSET = .TRUE.
    END IF
    IF (.NOT. IXSET) GO TO 20
    PK2 = PKTIME(IX-1,II)
    PK3 = AMIN1(TEND,PK1)
    IF ((PK3 .LE. PKTIME(NOPNTS(1),II)) .AND.
      (PK2 .NE. PKTIME(IX,II))) THEN
      PK = (PK3 - PK2) / (PKTIME(IX,II) - PK2) *
      (PKVAL(IX,I) - PKVAL(IX-1,I)) + PKVAL(IX-1,I)
    ELSE
      PK = PKVAL(IX,I)
    END IF
```

are used to compute the component probability of kill for one encounter. The first IF statement is used to branch out of the encounter loop to Statement 1900 if the end time for this interval is less than the minimum time required for a nonzero Pk. The first block IF ascertains whether the time for complete penetration is less than the minimum time for a nonzero Pk. If so, execution falls through to the end of the encounter loop. This event indicates that the component is completely perforated with a zero Pk, so the computation proceeds with the next encounter. The next block IF determines whether it is possible for the current component to be killed with a single shot line. If so, the maximum possible penetration time for this encounter, PK1, is the lesser of the times required to achieve a Pk of 1.0 and the time to achieve perforation of the component. If not, the maximum penetration time is the perforation

time. The third block IF statement checks whether the maximum penetration time occurred during a previous time interval. If so, execution falls through to the end of the encounter loop. If not, the program initializes an index IX and a stopping condition flag IXSET for a "DO WHILE" type loop. The loop, beginning with Statement 20 and ending with the conditional GO TO, determines the minimum time associated with any of the entered Pk values that is greater than or equal to the current time interval. The contained block IF statement is used to increment the Pk time index until this value is achieved or until the last Pk time value is exceeded. The variable PK2, the minimum penetration time for this time interval, is set to the time associated with the last Pk value before the end of the time interval. PK3, the maximum penetration time for this time interval, is the lesser of the end of the time interval and the maximum possible penetration time. The final block IF statement is used to compute PK, the probability of kill for the encounter. If the maximum penetration time for the interval is less than or equal to the penetration time that causes the highest Pk and if the minimum penetration time is not equal to the time for the next Pk value. PK is interpolated linearly between the nearest input Pk values. Mathematically this is expressed as:

$$Pk = \frac{(t_M - t_N)}{(t_{N+1} - t_N)} (Pk_{N+1} - Pk_N) + Pk_N \quad (3-18)$$

If the conditions of the block IF are not met, the ELSE branch is executed, implying that either the component has been penetrated beyond the depth that causes its greatest Pk or that upon penetration to a certain depth, the Pk is discontinuous. In both cases, the Pk associated with the time found in the "DO WHILE" loop is the desired Pk, so PK is set to this value.

The statements

```

SPK = PK
IF (AVFLAG .EQ. 0) PK = PK * (1.0 - PMX)
PKC(II) = PK
IF (II .NE. 1) THEN
  DO 172 LM = II-1, 1, -1
    IF (LOC(LM) .EQ. 1) THEN
      PK = PK * (1.0 - PKC(LM))
      PKC(II) = PKC(LM) + PK
    GO TO 175
  END IF
CONTINUE
172 ENO IF
175 ENO IF
CONTINUE

```

are used to compute the total shot line kill probability for the components by including the PK from any previous encounters. The first assignment statement is used to store the encounter PK value in the variable SPK, which is used for a system Pk computation. The IF statement is used to adjust the value of PK to obtain component incremental values if the area of vulnerability flag AVFLAG is reset; otherwise true values for component areas of vulnerability are obtained. The next statement is used to store the encounter Pk value in the PKC array. The succeeding block IF statement tests if this is the first shot line encounter. If so, program execution falls through to Statement 175. If this is not the first shot line encounter, the DO loop is used to search

for the most recent shot line encounter for the same component. If no previous encounter involved the same component, the block IF statement falls through to the end of the DO loop on every iteration and the value of PKC(II) remains unchanged. If a previous encounter has the same component, the assignment statements are used to compute the probability of kill on the IIth encounter using:

$$Pe_i = P_i \left(1 - \sum_{j=1}^{i-1} Pe_j \right) \quad (3-25)$$

The probability of this exclusive event is then added to the previous shot line Pk and is stored in PKC(II). The GO TO statement is then used to branch out of the loop.

The next statement

```
IF (SNGSYS) SPK = SPK * (1.0 - PKS(L))
```

is a logical IF statement used to adjust the system Pk value if the component is singly vulnerable. In this case, the system kill probability is the product of the encounter kill probability SPK, and the probability of system survival for all previous encounters (1-PKS(L)).

The statements

```

      IF (PKC(II) .GT. PRNT(3,I)) THEN
        PRNT(1,I) = SHW(1,IST)
        PRNT(2,I) = SHW(2,IST)
        PRNT(3,I) = PKC(II)
        PRNT(4,I) = PK3
      ELSE IF ((PKC(II) .EQ. PRNT(3,I)) .AND.
        (PRNT(4,I) .GT. PK3)) THEN
        PRNT(1,I) = SHW(1,IST)
        PRNT(2,I) = SHW(2,IST)
        PRNT(4,I) = PK3
      END IF

```

are used to store the maximum Pk encounter data for a component in the PRNT array. The block IF statement is used to compare the encounter Pk with the value already stored in the print array for the component. If the encounter Pk is greater than the value in the PRNT array, assignment statements store the shot line coordinates, the component kill probability, and the penetration time in the PRNT array. If the encounter Pk is not greater than the value in the PRNT array, the ELSE IF statement checks whether the encounter Pk is equal to the value in the PRNT array and whether the current penetration time is less than that stored in the PRNT array. If these conditions are met, the shot line coordinates and the penetration time are saved in the PRNT array. The END IF statement closes the block IF.

This statement

```
IF (TEND .LT. PK1) GO TO 1900
```

is used to branch out of the encounter loop if the maximum Pk encounter time, PK1, exceeds the interval end time. If there is time remaining in the time interval after this encounter, the program continues with the next statements.

These statements

```

IF (SNGSYS) PKS(L) = PKS(L) + SPK
TBEG = PK3
DO 500 NTI = NTIM,NTIME
  IF (SNGSYS) PMULT(L,NTI) = PMULT(L,NTI) + SPK
  COMPAV(I,NTI) = COMPAV(I,NTI) + PK
500 CONTINUE

```

are used to accumulate the system and component Pk's from this encounter, and to specify the start time. The first logical IF statement is used to sum the system Pk into the PKS array for singly vulnerable components only. The assignment statement is used to reassign the start time to equal the encounter end time. The DO loop is used to add the system Pk to the PMULT array, and the steps are inside of the encounter loop, the component Pk accumulation is expressed mathematically as:

$$Pk_j = \sum_{i=1}^N Pe_i \quad (3-26)$$

The logical IF statement inside the loop is used to allow only singly vulnerable system kill probabilities to be added to the PMULT array.

The statements

```

IF ((.NOT. MULSYS) .AND. (AVFLAG .EQ. 1)) THEN
  PMX = PMX + PK * (1.0 - PMX)
ELSE IF ((.NOT. MULSYS) .AND. (AVFLAG .EQ. 0)) THEN
  PMX = PMX + PK
END IF
END IF
END IF
1000 CONTINUE

```

are used to compute the shot line Pk and to end the encounter DO loop. The block IF is used to compute the shot line kill probability, excluding encounters with multiply vulnerable components. The shot line kill probability consists of the sum of the probabilities of exclusive events. If AVFLAG is set, the probability that the current encounter causes a kill is calculated using PK. If AVFLAG is reset, PK already equals the probability of kill for this encounter only. The three END IF statements end this block IF, the block IF where the beginning interval time is less than the maximum penetration time, and the block IF where the perforation time is at least equal to the time required for a nonzero Pk. Statement 1000 is used to end the encounter DO loop. This loop iterates until the time interval is completed or all components on the shot line are penetrated. Two IF statements inside the loop are used to branch to Statement 1900 when the time interval is completed. If all remaining components are penetrated during the time interval, the subroutine continues with the next statements.

The statements

```

      DO 1500 NTI = NTIM,NTIME
        SHW(NTI+2,IST) = PMX
1500  CONTINUE
      RETURN

```

are used to store the shot line Pk for the remaining time intervals and to return control to Program PEAKAY. This is the end point of Subroutine PENT for a shot line which is able to penetrate all of the encountered components within the specified time intervals. The DO loop is used to store the shot line Pk values in array SHW beginning with the element for the current time interval NTIM and continuing through all remaining time intervals.

The next statements

```

1900  CONTINUE
      IF (.NOT. MULSYS) THEN
        IF (AVFLAG.EQ. 1) THEN
          SHW(NTIM+2,IST) = PMX + PK * (1.0 - PMX)
        ELSE
          SHW(NTIM+2,IST) = PMX + PK
        END IF
      ELSE
        SHW(NTIM+2,IST) = PMX
      END IF
      IF (SNGSYS) PMULT(L,NTIM) = PMULT(L,NTIM) + SPK
      COMPAV(1,NTIM) = COMPAV(1,NTIM) + PK
6000  CONTINUE
      RETURN
      END

```

are executed only after an encounter or series of encounters has used an entire time interval. This condition is detected by using two IF statements which invoke a branch to Statement 1900 from inside the encounter loop. The outer block IF is used to store the shot line Pk values after the NTIM time interval in the SHW array. The first block IF statement determines if the component is multiply vulnerable. If not, the inner block IF calculates the shot line kill probability, taking into account whether the probability of kill for one encounter PK is a true value or an incremental value (probability of kill on one encounter and survival on all others). If the component is multiply vulnerable, the ELSE branch of the outer block IF is executed and the shot line kill probability is unaffected by the current encounter. The branch to Statement 1900 is executed before updating the shot line kill probability PMX to include the last encounter. Hence, this step requires an assignment statement and an IF statement to store the Pk values from the last encounter. The logical IF statement is used to add the system Pk value to the PMULT array if the encountered component is singly vulnerable. The last assignment statement is used to accumulate the component Pk values in the COMPAV array. Statement 6000 is used to end the time penetration loop. If all time intervals are processed without complete shot line penetration, the RETURN statement is used to return control to Program PEAKAY.

Intentionally Left Blank

PROGRAM PRERD

This program should be used before Program QKPK. It is used to check for possible errors in the input cards. The output from this program includes a table of the component information arrays with flags marking possible errors and several summaries of the data arranged by various parameters. All output is on Logical Unit 6, the line printer. Table 4-2 lists the data checks which are made in this program, and Table 4-3 lists the summaries that are printed. Any flagged error should be checked and corrected by the user since this program does not correct errors for the user.

The first set of statements

```

      INTEGER      PKNBR
      COMMON       ICOMP(500),MAT(500),IFG(500),ITAB(500),IANA(500),
&                TINIT(500),NOPNTS(500),DEPTH(10,500),PKVAL(10,500),
&                RMDF(500),IU(500),IY(500)

      DATA        IPLNK,ICMK,IASFR /' ','IHC','*'/
      DATA        IRD,INR /5,6/
      DATA        ITC,IFX,PKNBR /500,25,10/

```

is used to declare PKNBR as an integer, declare array dimensions, allocate common storage areas, and initialize the flag characters, input/output device numbers, and values of array dimensions. The initialization is done by using DATA statements.

The statements

```

      OPEN (IRD,FILE='QKPKDATA',WFCCF='DS',MAXRFL=80,PAD='YES')
      OPEN (INR,FILE='PRERDOUT',WFCCF='DS',CAHRAGE CONTRL='FORTRAN')

```

are used to connect logical units to the input and output files and to establish the connection properties between each unit/file pair.

The next two statements

```

      CALL READIN
      CALL FSORT(ICOMP,NOCOMP,MAT,IFG,ITAB,IANA,TINIT,NOPNTS,DEPTH,
&                PKVAL,ITC,PKNBR,THINFL,RMDF,IY,IU)

```

are used to execute two subroutines. Subroutine READIN is used to read the same input cards that Program QKPK will read and to make six of the tests listed in Table 4-2. Subroutine FSORT is used to sort the component information arrays into ascending order by component number.

The statements

```

      WRITE (INR,100)
      WRITE (INR,101)

```

are formatted WRITE statements which are used to print the heading for the component information table with flagged errors.

The next statements

TABLE 4-2. Data Tests Made by Program PRERD

Tested in Subroutine READIN:

1. Number of components exceeds component array dimensions (fatal error).
2. Number of points in the flux distribution exceeds array dimensions.
3. Flux level not within bounds (0.00 to 60000.0).
4. Number of points for which Pk values are to be entered exceeds array dimensions (fatal error).
5. Component information not in the expected format (fatal error).
6. Number of shot line time intervals for shot line breakdown not within array dimensions (fatal error).

Tested in Program PRERD:

1. Duplicate component identification numbers
2. Component identification number outside of the allowable range (1 to 9999)
3. Component criticality flag not equal to 0, 1, 2, or 3
4. Material identification code outside of the allowable range (1 to 11)
5. Table look-up code outside of the allowable range (1 to 9)
6. Material identification code and table look-up code both zero or both nonzero
7. Analysis type code not equal to 0, 1, or 2
8. Component initial operating temperature less than or equal to 0.0
9. Negative influence mode thickness, THINFL
10. Density factor RHOF outside of the allowable range (0.0 to 1.0)
11. Density factor and influence mode thickness both equal to 0.0 or both greater than 0.0
12. System number outside of the allowable range (0 to 10)
13. Singly vulnerable flag not equal to 0 or 1
14. System number equal to 0 and singly vulnerable flag not equal to 0
15. For depths of penetration and their associated probabilities P(K/H)
 - a. Number of elements in DEPTH and PKVAL arrays outside of allowable range (2 to 10)
 - b. Values of depth elements less than 0.0 or any two successive values decreasing in magnitude
 - c. Values of probabilities of kill outside of the allowable range (0.0 to 1.0) and any two successive values decreasing

TABLE 4-3. Component Information Summaries From Program PRERD.

1. Component data with any of the possible errors from Table 4-2 indicated
2. Critical component summary and count
3. Component listing and count by material code
4. Component listing and count by table look-up code
5. Component listing and count by analysis type
6. Component listing and count by system number

```

DO 110 J = 2, NOCOMP
  IF (ICOMP(J) .EQ. ICOMP(J-1)) THEN
    ICOMP(J) = -IABS(ICOMP(J))
    ICOMP(J-1) = -IABS(ICOMP(J-1))
  END IF
110 CONTINUE

```

are used to test for duplicate component identification numbers. After executing Subroutine FSORT, the component numbers in array ICOMP are in increasing order, so this test can be done by looping through the array and comparing only the adjacent elements. This is done by using a DO loop and an IF statement. If duplicate component numbers are found, they are temporarily flagged by setting them to negative values.

The statements

```

DO 199 J = 1, NOCOMP
  DO 120 I = 1, 34
    IE(I) = IRLNK
  120 CONTINUE

```

are used to initiate a loop which will flag errors and print the component information arrays for every component. The inner DO loop in the above statements is used to assign blank characters to the IE array. If errors are found, this array is assigned a flag character in a position corresponding to the error type and printed with the component information arrays.

The statements

```

IF (ICOMP(J) .LE. 0) IE(1) = ICHK
ICOMP(J) = IABS(ICOMP(J))
IF (ICOMP(J) .GT. 9999) IE(1) = ICHK

```

are used to finish the component identification number tests and set the first flag if an error is detected. The first IF statement is used to set the flag when the component number is negative or 0. The second IF statement is used to set the flag when the component number is greater than 9999. Any negative component numbers are made positive by using the IABS function. Since a negative number is also an indication of a duplicate component number, the first flag may indicate a duplicate component identification number or an identification number outside of the 1 to 9999 range.

The IF statement

```

IF ((IFG(J) .LT. 0) .OR. (IFG(J) .GT. 3)) IE(2) = ICHK

```

is used to set the second flag when the criticality flag is not equal to 0, 1, 2, or 3.

The next statements

```

IF ((ITAB(J) .EQ. 0) .AND. (MAT(J) .LT. 1) .OR.
  (MAT(J) .GT. 11)) IE(3) = ICHK
IF ((MAT(J) .EQ. 0) .AND. (ITAB(J) .LT. 1) .OR.
  (ITAB(J) .GT. 9)) IE(4) = ICHK
IF ((ITAB(J) .NE. 0) .AND. (MAT(J) .NE. 0)) THEN
  IE(3) = ICHK
  IE(4) = ICHK
END IF

```

are used to test the table look-up code and the material code for the Jth component. The third flag is set if the table look-up code is 0 and the material identification code is less than 1 or greater than 11. The fourth flag is set if the material identification code is equal to 0 and the table look-up code is less than 1 or greater than 9. Both flags are set if both ITAB(J) and MAT(J) are non-zero.

The next IF statement

```
IF ((IANA(J) .LT. 0) .OR. (IANA(J) .GT. 2)) IE(5) = ICHK
```

is used to set the first flag if the analysis type code is not equal to 0, 1, or 2.

The statement

```
IF (TINIT(J) .LE. 0.) IE(6) = ICHK
```

is used to test the component's initial operating temperature and to set the sixth flag if it is less than or equal to 0.00.

The statements

```
IF (THINFL(J) .LT. 0.) IE(9) = ICHK
IF ((RHOF(J) .LT. 0.) .OR. (RHOF(J) .GT. 1.)) IE(10) = ICHK
IF (((THINFL(J) .GT. 0.) .AND. (RHOF(J) .GT. 0.)) .OR.
  & ((THINFL(J) .LE. 0.) .AND. (RHOF(J) .LE. 0.))) THEN
  IE(9) = ICHK
  IE(10) = ICHK
END IF
```

are used to test and possibly set the 9th and 10 flags. The first IF statement is used to set the 9th flag if the influence mode thickness, THINFL, is less than 0.00. The second IF statement is used to set the 10th flag when the density factor, RHOF, is less than 0.0 or greater than 1.00. Both of these flags are set if the influence thickness and the density factors are greater than 0.0, or if they are both less than or equal to 0.00.

The statements

```
IF ((IY(J) .LT. 0) .OR. (IY(J) .GT. 10)) IE(11) = ICHK
IF ((IU(J) .LT. 0) .OR. (IU(J) .GT. 1)) IF(12) = ICHK
IF ((IY(J) .EQ. 0) .AND. (IU(J) .NE. 0)) THEN
  IF(11) = ICHK
  IF(12) = ICHK
END IF
```

are used to set the 11th and 12th flags if an error is detected in the system number array IY, or in the singly vulnerable flag array IU. The first IF statement is used to set the 11th flag when the system number is less than 0 or greater than 10. The next IF statement is used to set the 12th flag if the singly vulnerable flag is not equal to 0 or 1. Both flags are set if the system number is 0 and the singly vulnerable flag is not equal to 0.

The statements

```

      IF ((NOPNTS(J) .LT. 2) .AND. (NOPNTS(J) .GT. 10)) IF(13) = ICHK
      IF (DEPTH(1,J) .LT. 0.0) IE(14) = ICHK
      IF ((PKVAL(1,J) .LT. 0.0) .OR. (PKVAL(1,J) .GT. 1.0))
    $   IE(15) = ICHK
      IX = 2
165  CONTINUE
      IF ((DEPTH(IX,J) .LT. 0) .OR. (DEPTH(IX,J) .LT. DEPTH(IX-1,J)))
    $   IF(12+2*IX) = ICHK
      IF ((PKVAL(1,J) .LT. 0.0) .OR. (PKVAL(1,J) .GT. 1.0) .OR.
    $   (PKVAL(IX,J) .LT. PKVAL(IX-1,J))) IE(13+2*IX) = ICHK
      IX = IX + 1
      IF ((IX .LE. 10) .AND. (IX .LE. NOPNTS(J))) GO TO 165

```

are used to set the 13th through 33rd flags if an error is detected in the establishing of the laser penetration depths and the Pk's associated with them. The first IF statement is used to set the 13th flag when the number of points for penetration is less than 2 or greater than 10. The next IF statement is used to set the 14th flag when the minimum penetration for a non-zero Pk is negative. The third IF statement is used to set the 15th flag if the Pk associated with the first penetration depth is outside of the range 0.0 to 1.0. An index for the number of points entered is initialized at 2. A loop is then entered to check that each penetration depth is non-negative and that each successive depth is no less than the previous. If an error is detected, the next even flag is set. Likewise, the probability associated with each depth is checked to insure that it is within the range 0.0 to 1.0 and that it is no less than the previous Pk. If an error is detected, the next odd numbered flag is set. The index is incremented and the program branches to Statement 165 if NOPNTS penetration depths and Pk's have not been examined.

The next statements

```

      DO 170 I = 1,33
      IF (IE(I) .NE. IRLNK) THEN
        IE(34) = IASTER
        GO TO 180
      END IF
170  CONTINUE

```

are used to test the flag array, IE, and to mark the line with an asterisk if it contains a possible error. If any of the flags from the previous tests have been set, the assignment statement is used to place an asterisk character in the 34th array position and the next GO TO statement is used to branch out of the DO loop to Statement 180. If none of the flags have been set, the DO loop executes for 33 iterations, always bypassing the assignment statement in the block IF.

The statements

```

180  WRITE (IWR,190,10STAT=10S) IE(13),ICOMP(J),IE(1),IFG(J),IE(2),
    $   MAT(J),IE(3),ITAH(J),IE(4),IANA(J),IE(5),TIMIT(J),IE(6),
    $   THINFL(J),IF(9),RMOR(J),IF(10),IV(J),IE(11),IIR(J),IF(12),
    $   NOPNTS(J),IE(13),J,(DEPTH(K,J),IE(12+2*K),PKVAL(K,J),
    $   IE(13+2*K),K = 1,NOPNTS(J))
190  CONTINUE

```

are the last statements in the test loop, which is executed for every element in the component information arrays. The WRITE statement is used to print the component data for the Jth component with any flags that may have been set. After reaching Statement 199, the program returns to the beginning of the DO

loop where the flag array, IE, is reinitialized and the tests will be executed again for the next component. This is repeated until all components have been tested.

The statements

```

DO 235 I = 1,3
  NTYPE = 0
  DO 220 J = 1,NOCOMP
    IF (IFG(J) .EQ. I) THEN
      NTYPE = NTYPE + 1
      WRITE (IWR,190,IOSTAT=IOS) IE(13),ICOMP(J),IE(1),IFG(J),
        IE(2),MAT(J),IE(3),ITAB(J),IE(4),IANA(J),IE(5),TINIT(J),
        IE(6),THINFL(J),IE(9),RHOF(J),IE(10),IY(J),IE(11),IU(J),
        IE(12),NOPNTS(J),IE(13),J,(DEPTH(K,J),IE(12+2*K),
        PRVAL(K,J),IE(13+2*K),K = 1,NOPNTS(J))
    END IF
  220 CONTINUE
  WRITE (IWR,230) NTYPE,I
235 CONTINUE

```

are used to assemble and print the critical component summary. The criticality flag may have values of 0, 1, 2, or 3, but a 0 indicates a noncritical component, which will be excluded from this summary. The outer DO loop is used to test for the three remaining values. The variable NTYPE is used to count the number of each type of critical component, and is initialized to 0 at the start of this loop. The inner DO loop is used to cycle through the criticality flag array, IFG, for every component. Whenever the criticality flag matches I, the outer DO loop index, NTYPE, is incremented and the component information arrays are printed for the component. When the inner loop is completed, the last WRITE statement will be used to print the total number of components with the criticality flag I.

The statements

```

WRITE (IWR,300)
WRITE (IWR,101)
DO 330 I = 1,11
  NTYPE = 0
  DO 310 J = 1,NOCOMP
    IF (MAT(J) .EQ. I) THEN
      NTYPE = NTYPE + 1
      WRITE (IWR,190,IOSTAT=IOS) IE(13),ICOMP(J),IE(1),IFG(J),
        IE(2),MAT(J),IE(3),ITAB(J),IE(4),IANA(J),IE(5),TINIT(J),
        IE(6),THINFL(J),IE(9),RHOF(J),IE(10),IY(J),IE(11),IU(J),
        IE(12),NOPNTS(J),IE(13),J,(DEPTH(K,J),IE(12+2*K),
        PRVAL(K,J),IE(13+2*K),K = 1,NOPNTS(J))
    END IF
  310 CONTINUE
  WRITE (IWR,320) NTYPE,I
330 CONTINUE

```

are used to assemble and write the component listing according to material types. The first two WRITE statements are used to print the heading for this summary. This is followed by two nested DO loops. The outer loop is used to initialize the type counter, NTYPE, and loop through the 11 possible material codes. The inner loop is used to test the material code for each component and if it is type I, the component information arrays are printed for the component. The final WRITE statement is used to print the total number of components, NTYPE, with a material type code I. Note that a component with a material code equal to 0 is excluded from this table.

The statements

```

WRITE (IWR,400)
WRITE (IWR,101)
DO 430 I = 1,9
  NTYPE = 0
  DO 410 J = 1,NOCOMP
    IF (ITAR(J).EQ. I) THEN
      NTYPE = NTYPE + 1
      WRITE (IWR,190,IOSTAT=IOS) IE(13),ICOMP(J),IE(1),IFG(J),
        IE(2),MAT(J),IE(3),ITAH(J),IE(4),IANA(J),IE(5),TINIT(J),
        IE(6),THINFL(J),IE(9),WHOF(J),IF(10),IY(J),IE(11),IU(J),
        IE(12),NOPNTS(J),IE(13),J,(DEPTH(K,J),IE(12+2*K),
        PRVAL(K,J),IE(13+2*K),K = 1,NOPNTS(J))
    END IF
  410 CONTINUE
  WRITE (IWR,420) NTYPE,I
430 CONTINUE

```

are used to assemble and print a component summary by table look-up index. The first two WRITE statements are used to print the heading for this summary. This is followed by two nested DO loops which are used to test each component's table look-up index for each possible value and to print the component information for each component with a matching index. This method was also used in assembling the two previous summaries.

The statements

```

WRITE (IWR,500)
WRITE (IWR,101)
DO 530 I = 0,2
  NTYPE = 0
  DO 510 J = 1,NOCOMP
    IF (IANA(J).EQ. I) THEN
      NTYPE = NTYPE + 1
      WRITE (IWR,190,IOSTAT=IOS) IE(13),ICOMP(J),IF(1),IFG(J),
        IF(2),MAT(J),IE(3),ITAH(J),IE(4),IANA(J),IE(5),TINIT(J),
        IE(6),THINFL(J),IF(9),WHOF(J),IF(10),IY(J),IE(11),IU(J),
        IF(12),NOPNTS(J),IE(13),J,(DEPTH(K,J),IE(12+2*K),
        PRVAL(K,J),IE(13+2*K),K = 1,NOPNTS(J))
    END IF
  510 CONTINUE
  WRITE (IWR,520) NTYPE,I
530 CONTINUE

```

are used to assemble and print the component listing by analysis type. This procedure is the same as that used for the three preceding summaries. The analysis type summary groups the component information by analysis types 0, 1, and 2, by comparing analysis type values with I.

The following statements

```

WRITE (IWR,400)
WRITE (IWR,101)

```

```

      DO 630 I = 0,10
      NTYPE = 0
      DO 610 J = 1,NCOMP
      IF (IY(J) .EQ. I) THEN
      NTYPE = NTYPE + 1
      WRITE (IAR,190,IOSTAT=IOS) IE(13),ICOMP(J),IF(1),IFG(J),
      IF(2),MAT(J),IF(3),ITAR(J),IE(4),IANA(J),IE(5),TINIT(J),
      IF(6),THINFL(J),IF(9),RHOF(J),IF(10),IY(J),IF(11),IU(J),
      IF(12),NUPNTS(J),IF(13),J,(DEPTH(K,J),IF(12+2*K),
      PKVAL(K,J),IE(13+2*K),K = 1,NUPNTS(J))
      END IF
610   CONTINUE
      WRITE (IAR,620) NTYPE,I
630   CONTINUE

```

are used to assemble and write the component listing by system number. The statements are used to execute the identical procedure used for the four previous summaries. These steps group and print the component information for system numbers 0 through 10.

The final group of statements

```

      STOP
100  FORMAT ('* THE FOLLOWING DATA HAS BEEN READ AND CHECKED FOR ',
      $ 'ERRORS.'/' AN ASTERISK IN THE LEFTMOST COLUMN INDICATES A',

      END

```

are used to stop this program. The FORMAT statements are used to specify all output formats used by WRITE statements in this program.

SUBROUTINE PROPY

This subroutine is called by Subroutine RAT and is used to compute several properties for encountered metallic components. A large number of DATA statements are used to form a set of material property data from which the values are computed. The following properties are material dependent and are only computed once for each encounter: the coupling coefficient, component density, vapor temperature, melting temperature, and heat of fusion. The coupling coefficient is computed as the product of an intensity dependent factor and a thickness dependent factor. The interpolation scheme used to compute these two factors employs function values stored in arrays, but the argument values are generated in the coding. Two temperature dependent properties, thermal conductivity and specific heat, are computed every time this subroutine is executed. These two values are interpolated from arrays which contain both arguments and function values. All computed property values are transferred from this subroutine by using COMMON /PROP/.

The statements

```

SUBROUTINE PROPY

```

are DATA statements used to assign values to the material property data. Each of the 11 material types is identified in the comment statements preceding its group of DDATA statements. The contents of each array will be described along with the coding that uses the array.

The statements

```

MATL = MAT(N)
IF (ITER .EQ. 0) THEN
  T = TINIT(N)
  TVAP = TMELT(MATL,2)
  TMLT = TMELT(MATL,1)
  XLAMBD = HEATFU(MATL)

```

are used to obtain the material dependent characteristics from the materials property data. The first assignment statement is used to assign the material type for the component to the variable MATL. The last four assignment statements are used to determine the initial operating temperature T, the vapor temperature TVAP, the melting temperature TMLT, and the heat of fusion XLAMBD for the component in this encounter. The block IF statement is used to cause the execution of the statements in the THEN branch only when this is the first call to Subroutine PROPY for this encounter. The material characteristic variables are all in COMMON /PROP/ and, because of their global properties, retain their value on subsequent calls to this subroutine.

The statements

```

IF (MATL .GE. 11) THEN
  ALP = ALPHA(MATL,1)

```

are used to assign the coupling coefficient to the variable ALP if the encounter is with a bare metal. If the material code indicates a coated material, the ELSE branch of the block IF is executed.

The statements

```

ELSE
  IF (PEAKF .GE. 1.0E+04) THEN
    XVAL = 1.0E+04
    K = 11
    CONTINUE
    K = K + 1
    AVAL = K - 10
    IF (PEAKF .GT. XVAL*AVAL) GO TO 260
  ELSE
    XVAL = 1.0E+03
    K = 1
    CONTINUE
    K = K + 1
    AVAL = K - 1
    IF (PEAKF .GE. XVAL*AVAL) GO TO 310
  END IF
  YVAL = ALPHA(MATL,K-1) - ALPHA(MATL,K)
  EM = -YVAL / XVAL
  ALPF = ALPHA(MATL,K) + EM * (PEAKF - XVAL * (AVAL))

```

are used to interpolate a value for the intensity dependent factor of the coupling coefficient for a coated material from the ALPHA array, using flux level arguments of 0, 1000, 2000, 3000, 4000, 5000, 6000, 7000, 8000, 9000, 10000, 20000, 30000, 40000, 50000, and 60000 watts/cm². The block IF statement determines whether the flux is at least 10000 watts/cm². The statements in this branch are used to find the interval number K that contains the flux level PEAKF. The arguments 10000, 20000, 30000, 40000, 50000, and 60000 are the product XVAL*AVAL in the IF statement and correspond to interval numbers 11, 12, 13, 14, 15, and 16. The ELSE branch of the block IF is

executed only when the flux level PEAKF is less than 10000 watts/cm². The statements in this branch are used to find the interval K that contains the flux level PEAKF using flux arguments of 1000, 2000, 3000, . . . 10000, which correspond to interval numbers 2, 3, 4, . . . 11. The three assignment statements following the block IF are used to linearly interpolate a value for ALPF from the array ALPHA. This interpolation is written mathematically as:

$$\alpha_f = \alpha_K - \left(\frac{\alpha_{K-1} - \alpha_K}{\Delta X} \right) (f - X_K)$$

where

α_f = the interpolated result ALPF
 α_K = the Kth function value from the ALPHA array
 ΔX = the argument step size, XVAL
 f = the flux level, PEAKF
 X_K = the Kth argument value, (XVAL*AVAL)

The ALPHA array is doubly subscripted by the material type, MATL, and the interval number, K. Table 4-4 gives a tabular representation of the table being used for this interpolation scheme.

The next statements

```
DP = DPM / 0.0254
IF (DP .GE. 2.0E-01) THEN
  ALPT = ALPHAT(MATL,4)
```

are used to start the computation of the thickness dependent factor of the coupling coefficient. First, the component thickness is converted from meters to inches for use within Subroutine PROPY. The block IF statement is used to determine if the thickness DP is greater than or equal to the largest argument for the APMAT array. If it is, the THEN branch of the block IF is used to allocate the last element from array ALPHAT for the specific material type to the variable ALPT. If not, the ELSE branch is used to perform the interpolation.

The statements

```
ELSE
  IF (DP .GE. 5.0E-02) THEN
    XVAL = 5.0E-02
    K = 6
    CONTINUE
    K = K + 1
    XVAL = XVAL + 5
    IF (DP .GE. XVAL*AVAL) GO TO 360
```

are used to determine the interval number, K, which contains the component thickness DP, if the thickness is between 0.05 and 0.20 inch. The block IF statement is used to determine if the thickness is at least 0.05 inch. If it is, the THEN branch is used to compare the arguments 0.10, 0.15, and

TABLE 4-4. ALPHA.

0.20, corresponding to interval numbers 7, 8, and 9 with the thickness DP. The argument values are the product XVAL*AVAL in the IF statement. The IF statement is used to loop back to Statement 360 until the interval K, which contains the thickness DP, is found.

The statements

```

ELSE
  XVAL = 1.0E-02
  K = 1
  410 CONTINUE
  K = K + 1
  AVAL = K - 1
  IF (UP .GE. XVAL*AVAL) GO TO 410
END IF

```

are used to determine the interval K, which contains the thickness DP if the thickness is less than 0.05 inch. This search is similar to that executed by the previous group of statements, except that these steps use arguments of 0.01, 0.02, 0.03, 0.04, and 0.05 corresponding to interval numbers 2, 3, 4, 5, and 6, respectively.

The next statements

```

YVAL = ALPHAT(MATL,K-1) - ALPHAT(MATL,K)
EM = -YVAL/XVAL
ALPT = ALPHAT(MATL,K) + EM * (UP - XVAL * (AVAL))
END IF

```

are used to linearly interpolate a value for the thickness dependent factor, ALPT, from the array ALPHAT, using the interval between subscripts K-1 and K, for the specified material code. Table 4-5 is a tabular representation of the function being used for this interpolation scheme. The interpolation scheme is written mathematically as:

$$\alpha_t = \alpha_K - \left(\frac{\alpha_{K-1} - \alpha_K}{\Delta X} \right) (d - X_K)$$

where

α_t = the interpolated result ALPT
 α_K = the Kth function value from the ALPHAT array
 ΔX = the argument step size, XVAL
 d = the thickness DP
 X_K = the Kth argument value, XVAL*AVAL

The statements

```

ALPC = ALPF + ALPT
IF ((ALPC .LT. ALPHA(MATL,1)) .AND. (ALPC .GT.
  3 ALPHA(MATL,10))) THEN
  ALP = ALPC
ELSE IF (ALPC .GE. ALPHA(MATL,1)) THEN
  ALP = ALPHA(MATL,1)

```

```

ELSE
  ALP = ALPHA(MATL,16)
END IF
END IF

```

are used to complete the computation of the coupling coefficient for coated materials. The assignment statement is used to compute this coefficient as the product of two factors: ALPF, which is a function of intensity and ALPT, which is a function of thickness. This is followed by a block IF which is used to compare the computed coupling coefficient with the endpoints on the curve represented by array ALPHA. If the computed coefficient is within the tabular values, it is assigned to the variable ALP. If it is outside the table range, the coupling coefficient ALP is assigned a value equal to the closer endpoint of the curve.

The statements

```

RHO = DENSIT(MATL)
TEMP = (TMELT + T) / 2.
T = TEMP
END IF

```

are used to compute the component density and temperature for the material type. The first assignment statement transfers the density for the component material code to the variable RHO. The last two assignment statements are used to set the variables TEMP and T equal to a temperature halfway between the initial operating temperature and the melt temperature. These are the last of the material dependent properties for this encounter. Since the variables ALP, RHO, and T are all global (in COMMON /PROP/), the next call to Subroutine PROPY for the same encounter can start immediately at the next set of statements.

The statement

```
TEMP = T
```

begins the computation steps for the temperature dependent encounter properties. The temperature TEMP is the value which changes between calls to this subroutine and is the argument for the two interpolation procedures remaining in this subroutine.

The statements

```

MVAL = NINT(CONDUC(MATL,1,1)) + 1
IF (TEMP .LE. CONDUC(MATL,1,2)) THEN
  CVAL = CONDUC(MATL,2,2)
ELSE IF (TEMP .GE. CONDUC(MATL,1,MVAL)) THEN
  CVAL = CONDUC(MATL,2,MVAL)
ELSE
  DO 50 I = 2,MVAL
    IF (TEMP .LE. CONDUC(MATL,1,I)) THEN
      CVAL = CONDUC(MATL,2,I) - (CONDUC(MATL,1,I) - TEMP) *
        (CONDUC(MATL,2,I) - CONDUC(MATL,2,I-1)) /
        (CONDUC(MATL,1,I) - CONDUC(MATL,1,I-1))
      GO TO 100
    END IF
  50 CONTINUE
END IF

```

are used to interpolate a value for CVAL, the thermal conductivity, corresponding to the temperature TEMP from the array CONDUC. The CONDUC array

are used to interpolate a value for CVAL, the thermal conductivity, corresponding to the temperature TEMP from the array CONDOC. The CONDOC array has three subscripts: the first one identifies the material code, the second subscript equals 1 for the function arguments and equals 2 for the function values, and the third one corresponds to the points in the function table, beginning with the subscript equal to 2. The array element CONDOC(MATL,1,1) has the number of points in the function table, and CONDOC(MATL,2,1) is not used. The first assignment statement is used to store the number of data points in the integer variable NVAL. The second assignment statement is used to compute MVAL, the subscript of the last data point. The next three IF statements are used to determine if the temperature is within the function arguments. If the temperature is not within the function arguments, CVAL is assigned the function value corresponding to the argument closer to the temperature and the routine branches to Statement 100, bypassing the interpolation steps. The DO loop is used to find the argument interval containing the temperature TEMP. The IF statement in the loop is used to branch to the end of the loop until the correct interval is found. The assignment statement in the loop is used to perform a linear interpolation on the CONDOC array. The linear interpolation for CVAL is written mathematically as:

$$C_{val} = y_i - \left[\left(x_i - t \right) \left(\frac{y_i - y_{i-1}}{x_i - x_{i-1}} \right) \right]$$

where

y_i = the i th function value from the CONDOC array
 x_i = the i th argument value from the CONDOC array
 t = the temperature TEMP

The GO TO statement is used to branch out of the loop after a value for CVAL has been interpolated.

are used to interpolate a value for SVAL, the specific heat, from the array SPECIF. This array contains both arguments and function values in the same arrangement as the CONDOC array. The linear interpolation routine is identical to the one used in the preceding group of statements. Interpolation for SVAL is written mathematically as:

$$S_{val} = y_i - \left[\left(x_i - t \right) \left(\frac{y_i - y_{i-1}}{x_i - x_{i-1}} \right) \right]$$

where

y_i = the i th function value from the SPECIF array
 x_i = the i th argument value from the SPECIF array
 t = the temperature TEMP

The RETURN and END statements are used to return control to Subroutine RAT and end this program unit.

PROGRAM QKPK

This program requires two input files: a formatted file read by Subroutine RDATA and a binary LOS file for one view, which is the output of either Program CONMAG, FASTGEN, or SHOTGEN. These data are used to compute from three to eleven penetration times for each critical encounter along each shot line: the minimum time needed to achieve a nonzero kill probability, the minimum times needed to achieve from zero to eight intermediate kill probabilities, the minimum time needed to achieve a maximum kill probability (less than or equal to 1.0), and the time needed to completely perforate the component. This information is written on a binary output file which is used by Program PEAKAY to compute component kill probabilities and vulnerable areas. Program QKPK is also used to compute and print a breakdown of critical shot lines by times needed to reach maximum Pk. A critical shot line has at least one encounter with a critical component. A shot line reverse flag is provided so that a user may obtain data for the opposite view without generating a new LOS tape.

The first set of statements

```

DATA      RMHF(499),RMHF(500)/1.,1./
DATA      IECHO /1/

```

are DATA statements which are used to initialize the variables whose names appear in the DATA statement lists. The first DATA statement is used to initialize variables with values of current array dimensions. The second DATA statement is used to initialize the input and output device numbers. The next DATA statement is used to zero the MAXT array. The DATA statements for the 499th and 500th positions in the component information arrays are used to assign default component characteristics. These data will be used if the shot line data (binary file) describe an encounter with a component which has no component information input (formatted file). The final DATA statement is used to set the echo flag so that all binary output will also be written at the line printer.

The statements

```

OPEN (IRI,FILE='QKPKDATA',RECFM='DS',MAYRECL=80,PAD='YES')
OPEN (IWR,FILE='QKPKPRINT',RECFM='DS',CARRIAGE CONTROL='FORTRAN')
OPEN (IIN,FILE='QKPKTAPEIN',FORM='UNFORMATTED',RECFM='VARIABLE')
OPEN (IOUT,FILE='QKPKTAPEOUT',FORM='UNFORMATTED',RECFM='VARIABLE')

```

are used to connect logical units to the input and output files and to establish the connection properties between each unit/file pair.

The statements

```

CALL RDATA
IF (NTMAX .LE. 0) THEN
  NTMAX = IFMAX
  DO 3 I = 1,NTMAX
    TIMAX(I) = FTIM(I)
3  CONTINUE
END IF

```

are used to call Subroutine RDATA to read all formatted input for this program, and to fill the TIMAX array. The time intervals for shot line breakdown, TIMAX, is an optional input. The IF statement is used to determine if this input was included. If the values are not included, the DO loop and assignment statements are executed. The result is that array TIMAX contains values equal to the time intervals from the flux distribution and NTMAX equals the number of time intervals.

The statements

```

READ (IIN) AZ,EL,GHIN,IDVEH,YMAX,YMIN,ZMAX,ZMIN,RADEXP
IF (CINCH .LE. 0.) CINCH = 1.0
CMETER = CINCH*.0254
GRID = GRID * CINCH
YMAX = YMAX * CINCH
YMIN = YMIN * CINCH
ZMAX = ZMAX * CINCH
ZMIN = ZMIN * CINCH

```

are used to read the first record from the binary file and to convert the minimum and maximum viewing plane coordinates and grid sizes to inches. The conversion factor CINCH is assigned a default value of 1.0 by using the first IF statement whenever it has been read with a value less than or equal to 0.0. The factor for conversion from input units to meters, CMETER, is also computed.

The next statements

```

IF (IRVRS .EQ. 1) THEN
  Y1 = -YMAX
  YMAX = -YMIN
  YMIN = Y1
  EL = -EL
  AZ = AZ - 180.
  IF (AZ .LT. 0.) AZ = AZ + 360.
END IF

```

are used to reverse the viewing plane data whenever the shot line reverse flag is set. The first IF statement is used to test IRVRS, the shot line reverse flag. If it is equal to 1, the flag is set and the assignment statements are used to interchange and negate the minimum and maximum y-coordinates and to

compute the reversed view attack angles. The last IF statement is used to maintain a positive value for the azimuth attack angle.

The statement

```
CALL FSORT(ICOMP,NOCOMP,MAT,IFG,ITAR,IANA,TIN1,NOPNTS,DEPTH,
$ PKVAL,ITC,PKNRW,THINFL,MHOF,IY,IU)
```

is a CALL statement used to invoke Subroutine FSORT which sorts the component information arrays into ascending order by component number. The component numbers are the values in array ICOMP. The sort subroutine maintains correspondence among all the array arguments by subscript.

The statements

```
WRITE (IWR,1003)
DO 50 J = 1,NOCOMP
  WRITE (IWR,1004) ICOMP(J),IFG(J),MAT(J),ITAR(J),IANA(J),
$   TIN1(J),THINFL(J),MHOF(J),IY(J),IU(J),J,(DEPTH(I,J),
$   PKVAL(I,J),I=1,NOPNTS(J))
  DO 40 I = 1,NOPNTS(J)
    DEPTH(I,J) = DEPTH(I,J) * CMETER
  40 CONTINUE
  THINFL(J) = THINFL(J) * CMETER
50 CONTINUE
```

are used to print the component information arrays on the line printer and to convert DEPTH and THINFL values to meters. The first write statement is used to print the heading. The outer DO loop is used to print the component information and to convert the influence mode wall thickness THINFL to meters. The inner DO loop is used to convert each laser penetration depth DEPTH to meters.

The next statements

```
NENC = 0
IFILL = 0
IFM = IFMAX - 1
IFXM = IFX - 1
WRITE (IOUT) AZ,EL,GRID,IOVEH,YMAX,YMIN,ZMAX,ZMIN,NOCOMP
WRITE (IOUT) (ICOMP(I),IFG(I),IY(I),IU(I),NOPNTS(I),(PKVAL(J,I),
$ J=1,NOPNTS(I)),I=1,NOCOMP),IRVRS,IFMAX,(FTIM(I),FXCM(I),I=1,
$ IFMAX)
IF (IECHO.EQ. 1) THEN
  WRITE (IWR,1000) IOUT
  WRITE (IWR,1014) AZ,EL,GRID,IOVEH,YMAX,YMIN,ZMAX,ZMIN,NOCOMP
  WRITE (IWR,1015)
  DO 60 I = 1,NOCOMP
    WRITE (IWR,1016) ICOMP(I),IFG(I),IY(I),IU(I),
$   NOPNTS(I),(PKVAL(J,I),J=1,NOPNTS(I))
  60 CONTINUE
  WRITE (IWR,1017) IRVRS,IFMAX,(FTIM(I),FXCM(I),I = 1,IFMAX)
END IF
```

are used to initialize four variables, to write the first two records of the binary output file, and if the echo flag is set, to print the binary output values on the line printer. The variable NENC is used to count the number of encounters for each shot line and the variable IFILL to count the number of elements in the binary output arrays. The first two assignment statements are used to set these two counters equal to 0. The variable IFM is used to reference the next to last element in the flux arrays and variable IFXM is used to reference the next to last element in the array MAXT, which counts the critical shot line breakdown. The first binary WRITE statement is used to write the viewing plane description on the first record of the binary

output file. The second WRITE statement to device IOUT is used to write the component number array, criticality flag array, system number array, multiple vulnerability flag array, reverse flag, number of points in the flux distribution, and flux distribution with time intervals. The block IF is used to print the binary output values on the line printer when the echo flag is set.

The statements

```
100 CONTINUE
  READ (IIN) (DUM,(SH(I,J),I=1,2),(JH(I,J),I=1,5),J=1,170)
  DO 110 J = 1,170
```

are used to read the next record of LOS data and to initiate a DO loop to process these data. The LOS data on the binary input file are arranged in groups of 170, and are stored in 170 consecutive array locations by using an implied DO loop. Consequently, a DO loop must be executed 170 times to process each set of LOS data. When the DO loop execution has been completed, a GO TO statement is used to return to Statement 100 so that the next set of LOS data may be read and processed.

The statements

```
IF (JH(2,J) .EQ. 0) GO TO 5000
ICODE = MOD(JH(1,J),10)
NENC = NENC + 1
IF (NENC .GT. 100) GO TO 530
```

are used to test for the end of view indicator, unpack the end of shot line indicator, increment the number of encounters, and test for a bounds violation. The first IF statement is used to test for an end of view, $JH(2,J) = 0$, and if true, causes a branch to Statement 5000. This is the normal exit from the LOS data processing loop. The assignment statement for the variable ICODE uses the FORTRAN MOD function to unpack the right-most digit of $JH(1,J)$. The last two executable statements increment NENC, the number of encounters per shot line, and branch to Statement 530, where a fatal error message is printed if NENC is greater than 100. If NENC is small enough, the program continues with the next set of statements.

These statements

```
XLOS(NENC) = FLOAT(JH(3,J)) * 0.01 * C-METER
JHT(NENC) = JH(2,J)
```

are used to compute the line of sight thickness in meters from $JH(3,J)$ and store it in array XLOS. The last assignment statement is used to store the component number for encounter NENC in array JHT.

The statements

```
IF (IRVRS .EQ. 0) THEN
  OBU(NENC) = FLOAT(JH(4,J)) * 0.001
ELSE
  OBU(NENC) = FLOAT(JH(5,J)) * 0.001
END IF
```

are used to store the secant of the entrance obliquity angle in array OBU. The IF statement is used to test the shot line reverse flag. If the shot

line is not reversed, (IRVSR = 0), the program uses JH(4,J) for the secant of the obliquity angle; otherwise the program uses JH(5,J). Since the binary LOS file actually stores 1000 times the secant value, the JH array element value is multiplied by 0.001 to obtain the true secant value.

The statement

```
IF (ICODE .EQ. 9) THEN
```

is used to test for the end of shot line flag. If ICODE does not equal 9, the end of the shot line has not been reached and the program bypasses the block IF and continues execution at Statement 110, the last statement in the shot line data processing loop. Then, the program will branch to process more shot line data. When the end of the shot line is reached, the next statements will be executed.

These statements

```
IF (IRVRS .EQ. 1) CALL REVRSE(J)
DO 170 IR = 1,IFMAX
  PEAKF = FXCM(IR)
  FLX = FXM(IR)
  CALL RAT (RATES(1,IR),IR,MAXENC)
  IF (JFLAG .EQ. 0) GO TO 180
170 CONTINUE
```

are used to reverse the shot line, if required, and to compute the penetration rate for each flux level. The IF statement is used to test the shot line reverse flag, and if it is set, to call Subroutine REVRSE, which is used to interchange the order of the components along the shot line. The DO loop is used to compute the penetration rate at each level of flux. Assignment statements for variables PEAKF and FLX are used to store the flux level in COMMON /ONE/. These values are accessed by either of the subroutines PROPY or TABLE, depending upon which is called by the Subroutine RAT. The CALL statement is used to invoke Subroutine RAT which computes the rate of penetration at the IRth flux level for each component along the shot line. The argument array, RATES, is used to store the penetration rates. The first subscript for RATES is the encounter number and the second subscript is the flux index. The variable IFLAG is computed in Subroutine RAT and equals the number of the last critical encounter. If IFLAG equals 0, there are no critical components on the shot line and the IF statement is used to branch out of the loop.

The statements

```
180 JFILL = JFILL + 1
  PKTIRF(1,JFILL) = SH(1,1) * CINCH
  PKTIRF(2,JFILL) = SH(2,J) * CINCH
  DO 190 K = 3,PKNHR
    PKTIRF(K,JFILL) = 0.0
190 CONTINUE
  PLS(JFILL) = 0.
  II(JFILL) = NCWII
```

are used to store the next group of data in the binary output arrays. The

first assignment statement is used to increment IFILL, the subscript for the binary output arrays. The shot line y- and z-coordinates are converted to inches and stored in the first two elements of each row of the PKTIME array. The remaining elements in each row are set to 0.0 in the DO loop. A 0.0 is assigned to array PLS and the number of critical encounters on the shot line is stored in array I1 by executing the last two assignment statements.

The statements

```

      IF (NCRIT .EQ. 0) MAXT(IFXX) = MAXT(IFXX) + 1
      IF (IFILL .EQ. 200) THEN
        WRITE (IOUT) ((PKTIME(IX,JX),IX=1,10),PLS(JX),I1(JX),
          &
          JX=1,200)
        IF (IECHO .EQ. 1)
          &
          WRITE (IHW,1002) ((PKTIME(IX,JX),IX=1,10),PLS(JX),
          &
          I1(JX),JX=1,200)
        IFILL = 0
      END IF
      IF (TFLAG .NE. 0) THEN

```

are used to count the number of noncritical shot lines, write the binary output arrays (if they are full), and fall through to the end of the LOS data processing loop (if the shot line has no critical encounters). The first IF statement is used to add 1 to the last element in array MAXT, the number of noncritical shot lines if NCRIT, the number of critical encounters, equals 0. The next IF statement is used to determine if the binary output arrays are full. When IFILL equals 200, the arrays are written to device IOUT, using the binary WRITE statement and echoed to the line printer if the echo flag is set. The subscript IFILL is reset to 0 after the WRITE statements are executed. The binary output steps are skipped if IFILL is less than 200. The last IF statement is used to determine if there are no critical encounters and to bypass the block IF and continue execution at Statement 110.

The next statements

```

      TUSED = 0.
      TMAX = 0.
      TMAX1 = 1.E30
      IRUSED = 1
401  CONTINUE
      DO 499 II = 1,NENC

```

are only executed if the shot line has at least one critical encounter. They are used to initialize four variables and to initiate a DO loop which iterates for every encounter on the shot line.

The statements

```

      RBAR = 0.
      IRNOW = IRUSED
      TNOW = TUSED
      DISLFT = XLDS(II)

```

are used to initialize four variables and are the first steps in the encounter loop. The variable RBAR is the penetration rate and IRNOW is a subscript for the flux distribution array. TNOW represents the time used up to the present step. DISLFT is the distance remaining to be penetrated in encounter II.

The statements

```

410      CONTINUE
        RATE = RATES(II,IRNOW)
        IF (RATE .LE. 0.) GO TO 430
        IF (DISLFT .LE. (FTIM(IRNOW) - TNOW) * RATE) GO TO 420
        DISLFT = DISLFT - (FTIM(IRNOW) - TNOW)*RATE
        INOW = FTIM(IRNOW)
        IRNOW = IRNOW + 1
        IF (IRNOW .LE. IFMAX) GO TO 410
        IRNOW = IRNOW - 1

```

are used to compute the time step during which penetration ends for the IIth encounter on the shot line. The first assignment statement is used to set the variable RATE equal to the penetration rate for the IIth encounter and the IRNOWth time step in the flux distribution. The first IF statement is used to branch to Statement 430 when the rate is 0.00. The second IF statement is used to branch to Statement 420 if the penetration is completed during time step IRNOW. If both tests fail, two assignment statements are used to compute DISLFT, the distance left to penetrate after time step IRNOW, and TNOW, the time after this time step. Next, IRNOW is incremented and the IF statement is used to branch back to Statement 410 to compute penetration for the next step in the flux distribution. If these steps iterate through the entire flux distribution without complete penetration, the last IF statement fails, and IRNOW is decremented so that it points to the last step in the distribution.

The statements

```

420      CONTINUE
        TNOW = TNOW + DISLFT / RATE
        TLOS = TNOW - TUSED
        RBAR = XLUS(II) / TLOS

```

are used to compute TNOW, the time of complete component penetration, and RBAR, the average penetration rate for the encounter. These steps are bypassed if the penetration rate becomes 0.0 before complete penetration.

The statements

```

430      CONTINUE
        J = JMT(II)
        IF (IFG(II) .NE. 0) THEN
            IFILL = IFILL + 1
            PLS(IFILL) = TNOW
            II(IFILL) = JMT(II)
            THRAT1(I) = AMAX1(THRAT1(I),DEPTH(I,I) * ORQ(II) /
3              XLUS(II))
            THRAT2(I) = AMAX1(THRAT2(I),DEPTH(NOPNTS(I),I) *
3              ORQ(II) / XLUS(II))

```

are used to store the data for complete penetration in the binary output arrays. If the encountered component is a critical one, the statements in the block IF are executed; otherwise the program continues execution at Statement 110, the last statement in the shot line data processing loop. Three assignment statements are used to increment IFILL, to store the time for complete penetration in the PLS array, and to store the component number location in array II. The values for insertion in the THRAT1 and THRAT2 arrays are computed using the AMAX1 function and are used to store the ratios DEPTH(I)*OBQ/XLOS and DEPTH(NOPNTS)*OBQ/XLOS for the encounter with the

smallest non-zero line of sight thickness for the Ith component.

The statements

```

      ON 440 K = 1,10
      PKTIME(K,IFILL) = 0.0
440    CONTINUE
      IF (RRAR .GT. 0.) THEN
      ON 450 K = 1,NOPNTS(I)
      PKTIME(K,IFILL) = DEPTH(K,I) * ORQ(II) / RRAR +
      TUSED
450    CONTINUE

```

are used to compute and store the time required to penetrate to the specified depth to obtain the associated Pk. The first DO loop is used to initialize the PKTIME array to zero. The IF block is executed if the average penetration rate for the component is greater than zero. The DO loop in the block IF is used to compute the total time required to penetrate the component to obtain the Pk values entered in the array PKVAL.

The statement

```

      IF ((PKTIME(NOPNTS(I),IFILL) .LE. PLS(IFILL))
      .AND. (PKVAL(NOPNTS(I),I) .EQ. 1.0))
      TMAX1 = AMINI(TMAX1,PKTIME(NOPNTS(I),IFILL))

```

is used to compute TMAX1, the earliest time that a component Pk equal to 1.0 occurs on this shot line. The IF statement is used to exclude encounters which complete penetration before attaining Pk = 1.00.

The next statements

```

      IF (PKVAL(NOPNTS(I),I) .EQ. 1.0) THEN
      TMAX = AMAX1(TMAX,AMINI(TNOW,PKTIME(NOPNTS(I),
      IFILL)))
      ELSE
      TMAX = AMAX1(TMAX,AMINI(TNOW,PLS(IFILL)))
      END IF

```

are used to compute TMAX, the minimum time needed to process all components on this shot line. The block IF statement determines whether it is possible to guarantee a kill of a component with a single shot line. If so, the assignment statement in the THEN branch is executed; otherwise, the ELSE branch is used. The AMINI function is used to select the minimum time to complete the current encounter. The AMAX1 function is used to select the greatest time for all encounters by comparing the value of TMAX from all previous encounters with the time for the current encounter. A completed encounter requires complete penetration of the component or a Pk equal to 1.0, whichever occurs first.

The statements

```

      IF (IFILL .EQ. 200) THEN
      WRITE (IOUT) ((PKTIME(IJ,JX),IJ=1,10),PLS(JX),
      11(JX),JX=1,200)
      IF (IFCHO .EQ. 1)
      WRITE (IWR,1002) ((PKTIME(IJ,JX),IJ=1,10),
      PLS(JX),11(JX),JX=1,200)
      IFILL=0
      END IF

```

```

      END IF
      END IF
      TUSED = INOW
      IRUSED = IRNOW
499   CONTINUE

```

are used to write another record of the binary output file, if the binary output arrays are full, and to end the encounter DO loop. The block IF statement is used to determine when the binary output arrays are full. When they are full, the binary WRITE statement is executed and if the echo flag is set, the formatted WRITE statement is executed. The output array index, IFILL, is reset equal to 0 following the WRITE statement execution. The block IF statements determining whether the binary output arrays are full, whether the average penetration rate is greater than zero, and whether the encountered component is a critical one are closed with the three END IF's. The next assignment statement is used to set TUSED equal to the time for complete penetration of this encounter and the last assignment statement is used to set IRUSED equal to the flux step number during which complete penetration was attained. Statement 499 is used to end the encounter DO loop.

The statements

```

      TMAX1 = AMIN1(TMAX,TMAX1)
      DO 500 I=1,NTMAX
        IF (TMAX1 .LE. TIMAX(I)) THEN
          MAXT(I) = MAXT(I) + 1
          GO TO 510
        END IF
500    CONTINUE
      MAXT(IFXM) = MAXT(IFXM) + 1
510    CONTINUE

```

are executed after each shot line is processed and are used to compute the breakdown of the shot line by the time required to achieve maximum Pk. First, TMAX1 is recomputed to be the minimum of the time needed to completely process the shot line and the time needed to reach a component Pk = 1.00. The DO loop is then used to cycle through the time intervals for shot line breakdown. The IF statement is used to find the time interval I in which TMAX1 falls. After the time bin I is found, the assignment statement is used to increment MAXT(I) and the GO TO statement is executed to branch out of the loop. The assignment statement following Statement 500 is executed only if TMAX1 is greater than all of the time intervals for shot line breakdown. It is used to increment the next to last array location of MAXT.

The statements

```

      HENC=0
      END IF
      END IF
110   CONTINUE
      GO TO 100

```

represent the end of the LOS data processing loop. The assignment statement is used to reset the number of shot line encounters to 0 and is executed after a complete shot line has been processed. The END IF statements close the block IF determining whether the shot line has any critical encounters and whether the end of the shot line has been reached. Statement 110 is used to end the DO loop, which is executed for each of the 170 LOS data array elements

The GO TO statement is used to branch back to read and process a new set of LOS data.

The next statements

```
5000 CONTINUE
    IFILL = IFILL + 1
    DO 120 J = IFILL,200
        I1(J) = 9999
    120 CONTINUE
```

are executed after an end of view has been detected in the binary LOS input data. The first assignment statement is used to increment IFILL, the number of values in the binary output arrays. The DO loop then is used to fill the remainder of the binary output array, I1, with an end of view flag, 9999.

The statements

```
WRITE (IOUT) ((PKTIME(I1,J1),I1=1,10),PLS(J1),I1(J1),J1=1,200)
IF (IFCHO .EQ. 1) THEN
    WRITE (IHW,1002) ((PKTIME(I1,J1),I1=1,10),
    * PLS(J1),I1(J1),J1=1,[FILL-1])
    WRITE (IHW,1001)
END IF
```

are used to write and echo the last binary output record. The end of view is indicated in this set of 200 array elements by the value 9999 in array I1. The block IF is used to test the echo flag; and, if it is set, to print the shot line data before the end of the view occurs and to print an end of echo message using formatted WRITE statements.

The next statements

```
WRITE (IHW,1005) MAXT(FXX)
NSL = MAXT(FXX)
IF = 0.
JF = 1
FE = FXXM(1)
DO 520 I = 1,NTMAX
    TE = FE
    FE = TIMAX(I)
    FA = FE
```

are used to begin assembling the breakdown of critical shot lines by times needed to reach maximum Pk. The first WRITE statement is used to print the number of noncritical shot lines and the heading for shot line breakdown. The next four assignment statements are used to initialize four variables: NSL is used to count the critical shot lines, TE is the end time, JF is the subscript for the flux table, and FE is the end flux level. The DO statement is used to initiate a loop to iterate through each time interval for shot line breakdown, and the next three assignment statements are used to determine begin time, end time, and begin flux level for the Ith time interval.

The statements

```
IF = JF
DO 510 J = JFF,IFM
    JF = J
```

```

        IF (TE .LE. FTIM(J)) GO TO 519
        IF (TE .LE. FTIM(J+1)) THEN
            JF = J + 1
            GO TO 519
        END IF
518    CONTINUE
        JF = IFMAX
519    FF = FXCM(JF)
        WRITE (IWR,1006) TB,TE,FB,FE,MAXT(I)
        NSL = NSL + MAXT(I)
520    CONTINUE

```

are used to find the flux level at the interval end time and to print the shot line breakdown. The DO loop is used to search the FTIM array to obtain the time interval, JF, which includes TE. The assignment statement following Statement 518 is executed only if the end time is greater than all values in the FTIM array. In this case, the last flux level in the distribution is the end flux level. The WRITE statement is used to print the shot line breakdown. The variable NSL is computed in the last assignment statement and is used to count the total number of critical shot lines. Statement 520 is used to end the DO loop which is executed for every shot line time interval.

The statements

```

TB = TE
TF = 1.E30
FB = FE
FE = FXCM(JFMAX)
WRITE (IWR,1006) TB,TF,FB,FE,MAXT(IFXM)
WRITE (IWR,1011) NSL
NSL = NSL + MAXT(IFXX)
WRITE (IWR,1012) NSL

```

are used to print a summation of critical shot line breakdowns. The first four assignment statements are used to compute the begin time, end time, begin flux, and end flux for the last interval. The end time, TE, is assigned a value of 10^{30} to imply that this interval applies to all times greater than the last begin time. Two WRITE statements are used next to print the last line of the breakdown table and the total number of shot lines. The last assignment statement is used to add the number of noncritical shot lines, MAXT(IFXX), to the number of critical shot lines, NSL. The last WRITE statement is then used to print the total number of shot lines.

The statements

```

WRITE (IWR,1009)
DO 600 J = 1,NCOMP
    IF (THRAT1(J) .GT. 1.0) THEN
        WRITE (IWR,1010) ICOMP(J),THRAT1(J),THRAT2(J)
    ELSE IF (THRAT2(J) .GT. 1.0) THEN
        WRITE (IWR,1013) ICOMP(J),THRAT2(J)
    END IF
600 CONTINUE

```

are used to print the last page of QKPK output, which consists of a list of all components having at least one encounter where the LOS thickness is less than that necessary to achieve a non-zero Pk or that necessary to achieve the maximum Pk for a single encounter of the component. In these cases, the component is completely perforated before a non-zero or a maximum Pk value is obtained. The first WRITE statement is used to test the arrays THRAT1 and THRAT2 for each component. The first condition of the block IF statement is used to detect components with a LOS thickness less than that necessary to

achieve a non-zero Pk. When such a component is found, the WRITE statement is executed and execution then falls through to the end of the loop. The second condition of the block IF is used to test for a component with a LOS thickness less than that necessary to achieve the maximum Pk for a single encounter of the component. When such a component is found, the last WRITE statement is executed. Execution then continues with Statement 600, the end of the loop. Entries in this table of output indicate possible errors in the selection of DEPTH values to achieve the non-zero Pk and the maximum Pk.

The statements

```

      STOP
530 CONTINUE
      WRITE (IWR,1008) NENC
      STOP

```

are used to stop the execution of this program. The first STOP statement is used to halt program execution and is the normal end point for this program after completely processing the shot line data for one view. The statements after Statement 530 are executed only if the number of encounters for one shot line exceeds 100. The WRITE statement is used to print an error message. The last STOP statement is used to halt program execution after the fatal error.

The last group of statements

```

```

is used to define all input and output formats and to end Program QKPK.

SUBROUTINE RAT

This subroutine is used to compute the penetration rate for each encounter along a shot line. Program QKPK calls Subroutine RAT once for every level of flux in the flux distribution. The computed rates are stored in the array RATES, subscripted by encounter number. The penetration rate for a component may be computed by using one of three methods: melt-in-place analysis, melt-removed analysis, or table look-up. The first two methods are used for metallic components and use Subroutine PROPY. The third method uses Subroutine TABLE.

The first set of statements

```

SUBROUTINE RAT (RATES,IR,MAXENC)
DIMENSION LOC(100),RATES(MAXENC)
COMMON ICOMP(500),MAT(500),IFG(500),ITAB(500),IANA(500),
$ TINIT(500),NOWNTS(500),DEPTH(10,500),PKVAL(10,500),
$ NMOF(500),INVS,10(500),IY(500)
COMMON THINFL(500),SM(2,170),JM(5,170),CINCH
COMMON /ONE/ NUCOMP,FLX,IFLAG,PEAKF,NCHIT
COMMON /TWO/ XLOS(100),JHT(100),NENC,UHQ(100)
COMMON /THOP/ ALP,KHX,CF,TMLT,XLAMBU,WATE,JCOMP,J,DP,XK,TVAP,
$ CPL,ITER,I
COMMON /SIZES/ ITC,IFX,IFXA

```

is used to facilitate transferring data among subroutines and to declare array dimensions. The SUBROUTINE statement is used to accept three arguments: the rates array, the subscript for the flux distribution, and the dimension of the rates array. The DIMENSION statement is used to establish a local integer array LOC and to declare the argument RATES to be a one dimensional array. Note that RATES is a two dimensional array in the calling program, but subroutine RAT can only be used to place values in array positions for a constant flux index IR, the second subscript. Five COMMON statements are used to transfer data and to declare array dimensions.

The statements

```

IF (IR .EQ. 1) THEN
  IFLAG = 0
  NCHIT = 0
  DO 100 I = 1,NENC
    JCOMP = JHT(I)
    CALL BSRCH(ICOMP,NUCOMP,ITC)
    LOC(I) = J
    IF (IFG(J) .NE. 0) THEN
      NCHIT = NCHIT + 1
      IFLAG = 1
    END IF
  100 CONTINUE
  NENC = IFLAG
  IF (IFLAG .EQ. 0) RETURN
END IF

```

are executed once for each shot line. They are used to build the component number link array LOC and to count the number of critical encounters on the shot line. The first block IF statement is used to test the argument IR, which equals 1 the first time Subroutine RAT is called for a shot line. When IR is greater than 1, the block IF is bypassed; otherwise, the DO loop is executed for each encounter on the shot line. The encounter component number is assigned to JCOMP. Subroutine BSRCH is invoked to search the component

number array, ICOMP, to find the subscript J for the component number matching JCOMP. The assignment statement following the CALL statement is used to store the subscript J in the LOC array. The next block IF statement determines if the encounter is with a critical component. If not, execution continues at the end of the loop; otherwise, the two assignment statements in the THEN branch are used to count the number of critical components on the shot line, NCRIT, and to save the encounter number of the last critical encounter in IFLAG. After the DO loop is completed, the next assignment statement is used to reassign the number of components, NENC, so that any noncritical encounters at the end of the shot line are excluded. The IF statement is used to return to Program QKPK if there are no critical encounters on the shot line. In this case, the variable IFLAG is also tested in Program QKPK so that this subroutine will not be invoked again for the same shot line.

The statements

```
DO 300 I = 1, NENC
  J = LOC(I)
  DP = XLOS(I)
```

are used to initiate a DO loop which will iterate for every encounter. The first assignment statement is used to get the subscript, J, for the component information arrays from the LOC array. The next assignment statement is used to set DP equal to the component LOS thickness.

The next statements

```
IF (IR .EQ. 1) THEN
  IF (THINFL(J) .GT. 0.) THEN
    DP = THINFL(J) * OSW(I)
  ELSE
    DP = XLOS(I) * RMOF(J)
  END IF
  XLOS(I) = DP
END IF
NATE = 0.
```

are used to compute the actual component thickness for the encounter. The first block IF statement is used to bypass these steps if the XLOS values have already been computed for this shot line. The next block IF statement is used to determine which method to use in computing the actual thickness. If the influence mode thickness is greater than 0.0, the THEN branch of the block IF will be used to compute the actual thickness as the product of the wall thickness and the secant of the obliquity angle. This value (in meters) is assigned to DP (the variable THINFL was converted to meters in Program QKPK). If the other method is used, the ELSE branch of the block IF will be used to compute the product of the LOS thickness (converted to meters in Program QKPK) and the input density factor of that component. The actual thickness for the Ith encounter is stored in the XLOS array, using the assignment statement following the end of the second block IF. The last assignment is used to initialize the variable to be zero.

The statements

```
IF (DP .GT. 0.) THEN
  IF (ITAN(J) .EQ. 0) THEN
```

are used to determine the appropriate method for computation of the penetration rate. If the component thickness is less than or equal to 0.0, the THEN branch of the first block IF is not executed, thereby bypassing all rate computations and resulting in a rate equal to 0.00. The second block IF statement determines whether a table look-up code has been specified. If not, the THEN branch is executed; otherwise, the ELSE branch is used.

The next statements

```
- ITER = 0
CALL PROPY
CPS = CP
RHO = RMX
```

are used to begin a rate computation, using one of the analysis types. The first two statements are used to call Subroutine PROPY with the iteration flag equal to 0. Subroutine PROPY is used to compute the material dependent properties--melting temperature, vapor temperature, heat of fusion, coupling coefficient, and density--and the temperature dependent properties--thermal conductivity and specific heat. The last two assignment statements are used to transfer the specific heat value to variable CPS and the density value to variable RHO.

The statements

```
IF (IANA(J) .EQ. 1) THEN
  ITER = 1
  T = TMLT
335 CONTINUE
  CALL PROPY
  TSTAR = TMLT + FLX * ALP * DP / XK
  IF (ABS(T-TSTAR) .GE. 100.) THEN
    T = TSTAR
    GO TO 335
  END IF
```

are used to compute the component's temperature rise for the melt in place analysis mode. The first block IF statement determines whether the melt in place analysis type is specified. If so, the statements in the THEN branch are executed; otherwise, the ELSE branch is executed. The next two assignment statements are used to set the iteration flag, ITER, equal to 1 and the temperature, T, equal to the melting temperature. The rest of the statements form a loop which is used iteratively to compute the limit of the temperature rise. Since the iteration flag ITER equals 1, Subroutine PROPY recomputes the temperature dependent properties--thermal conductivity, XK, and specific heat, CP. The assignment statement following the CALL statement is used to compute the new temperature TSTAR. The mathematical expression for computing TSTAR is:

$$T^* = T_m + \frac{\alpha FZ}{k}$$

(3-12)

The second block IF is used to branch out of the loop when the temperature rise, i.e. the change in temperature, is less than 100 from the previous loop.

The next statements

```

      IF ((TSTAK .GT. TVAP) .AND. (TVAP .GT. 0.)) THEN
        STAR = XK * (TVAP - TMLT) / UP
        RATE = STAR / (RHO * (CPS * (TMLT - TINIT(J)) +
          XLAMB0 + CP * .5 * (TVAP - TMLT)))
      ELSE
        RATE = FLX * ALP / (RHO * (CPS * (TMLT - TINIT(J)) +
          XLAMB0 + CP * (.5 * (TSTAK + TMLT) - TMLT)))
      END IF

```

are used to compute the penetration rate for the melt in place analysis type. The block IF statement is used to determine which of two melt in place rate equations should be used. If the peak temperature is greater than the vapor temperature and the vapor temperature is positive, the rate equation in the THEN branch will be used. This equation in mathematical form is:

$$R = \frac{k \frac{(T_v - T_m)}{Z}}{\rho \left[Cps (T_m - T_1) + \lambda + Cp \ell \left(\frac{T_v - T_m}{2} \right) \right]} \quad (3-16)$$

If the peak temperature does not exceed the vapor temperature or the material type has a vapor temperature of 0, the second melt in place rate equation in the ELSE branch will be used. The mathematical form of the second rate equation is:

$$R = \frac{\alpha F}{\rho \left[Cps (T_m - T_1) + \lambda + Cp \ell \left(\frac{T^* + T_m}{2} - T_m \right) \right]} \quad (3-10)$$

The statements

```

      ELSE
        RATE = FLX * ALP / (RHO * (CP * (TMLT - TINIT(J)) +
          XLAMB0))
      END IF

```

are used to compute the penetration rate for the melt removed analysis type. This rate equation is written mathematically as:

$$R = \frac{\alpha F}{\rho [Cps (T_m - T_1) + \lambda]} \quad (3-7)$$

The statements

```

      ELSE
      CALL TABLE
    END IF
  END IF

```

invoke Subroutine TABLE when a look-up code has been specified to compute a penetration rate for nonmetallic components.

The statements

```

      RATES(I) = RATE
      JHT(I) = J

```

are used to store the penetration rate and to reassign the component link. The first assignment statement is used to store the computed penetration rate in the array, RATES, indexed by the encounter number. The second assignment statement is used to store the component information array's subscript J in the JHT array. This array previously contained the component identification numbers.

The final group of statements

```

300 CONTINUE
    RETURN
    END

```

contains Statement 300, the last statement in the encounter loop. After a penetration rate has been computed and stored for every encounter on the shot line, the RETURN statement will be used to relinquish control to Program QKPK. The END statement is used to conclude this program unit.

SUBROUTINE RDATA

This subroutine is used by Program QKPK to read the formatted input deck. The data in this deck include: number of components, shot line reverse flag, units conversion factor for the input, flux distribution table, and, optionally, time intervals for shot line breakdown. Subroutine RDATA is also used to print the flux distribution table, the first page of output from Program QKPK, and to test the flux values and the number of components. An error detected by these tests will halt program execution. The same tests are made by Program PRERD and any error should be corrected before proceeding to Program QKPK.

The statements

```

SUBROUTINE RDATA
COMMON ICOMP(500),MAT(500),IFG(500),ITAB(500),IAMA(500),
$      IT(500),NPOINTS(500),DEPTH(10,500),PKVAL(10,500),
$      QMVF(500),IRVRS,IU(500),IY(500)
COMMON IWINFL(500),SM(2,170),JM(5,170),CINCH
COMMON /ONE/ NOCOMP,FLX,IFLAG,PEAKE,NCRTT
COMMON /TWO/ XLQS(100),JMT(100),NENC,DMQ(100)
COMMON /THREE/ MATFS(100,25),FTIM(25),FXCM(25),FXM(25),IFMAX,
$      ITMAX(25),MAXT(27),NTMAX
COMMON /LUNITS/ IRD,IWM,IH,IOUT
COMMON /SIZES/ ITC,IFX,IFXX

```

are used to establish array dimensions and common storage allocations. Data for variables are transferred to and from other program units by using the common storage areas.

The next statements

```

READ (IRD,1000) NOCOMP
IF (ITC .GE. NOCOMP+2) THEN
  READ (IRD,1000) IRVRS,CINCH
  READ (IRD,1000) IFMAX
  READ (IRD,1002) (FXCM(I),I=1,IFMAX)
  READ (IRD,1002) (FTIM(I),I=1,IFMAX)

```

are used to read the number of components, NOCOMP, and, if the value read is not too large, to read the shot line reverse flag, the input unit conversion factor, and the flux table. If NOCOMP is too large, the ELSE branch of the block IF is executed.

The statements

```

WRITE (IWR,2000) NOCOMP,IRVRS,CINCH
WRITE (IWR,2001) IFMAX
TE = 0.
DO 110 I = 1,IFMAX
  TR = TE
  TE = FTIM(I)
  WRITE (IWR,2002) TR,TE,FXCM(I)
110 CONTINUE
TR = TE
TE = 1.E30
WRITE (IWR,2002) TR,TE,FXCM(IFMAX)

```

are used to print the first page of QKPK output. The first two WRITE statements are used to print the number of components, the shot line reverse flag, the input unit conversion factor, and the number of points in the flux distribution. The DO loop is used to print the flux distribution table in a format that shows a flux level, FXCM(I), lasting for a time interval, TB to

TE. Since the last flux level applies to all times greater than the last time in array FTIM, an extra line is printed in the flux table with an end time value of 10^{30} . This value requires more digits than the format for the last WRITE statement will allow, so the end time for this flux level is printed as a row of asterisks, symbolizing an infinite end time.

The statements

```

DO 160 I = 1, IFMAX
  IF ((FXCM(I) .GT. 0.) .AND. (FXCM(I) .LE. 6.0E+04)) THEN
    FXM(I) = FXCM(I) * 10000.
  ELSE
    WRITE (IWR,100) FXCM(I)
    STOP
  END IF
160 CONTINUE

```

are used to check if each flux level is within the acceptable range (0.0 to 60000.0 watts/cm²) and to convert the flux values to another unit, watts/m². The DO loop is used to cycle through each of the IFMAX flux levels. The block IF statement is used to test the flux level. If the flux level passes the test, the flux value is converted to watts/m² and is stored in array FXM. If the flux level is too low or too high, the WRITE statement is used to print a warning message and the program stops.

The statements

```

DO 40 I = 1, NOCOMP
  READ (IRD,1001,IOSTAT=IOS) ICOMP(I),MAT(I),IFG(I),ITAB(I),
  S IANA(I),IINIT(I),THINFL(I),RHOF(I),IV(I),IH(I),NOPNTS(I)
  IF (IOS .EQ. 0) THEN
    IF ((NOPNTS(I) .LT. 2) .OR. (NOPNTS(I) .GT. 10)) THEN
      WRITE (IWR,1010) I, NOPNTS(I)
      STOP
    ELSE IF (NOPNTS(I) .GT. 4) THEN
      READ (IRD,1001,IOSTAT=IOS)
    END IF
  END IF
  IF (IOS .GT. 0) THEN
    WRITE (IWR,1015) I
    WRITE (IWR,1001,IOSTAT=IOS) ICOMP(I),MAT(I),IFG(I),ITAB(I),
  S IANA(I),IINIT(I),THINFL(I),RHOF(I),IV(I),IH(I),NOPNTS(I)
    STOP
  ELSE IF (IOS .LT. 0) THEN
    WRITE (IWR,1020,IOSTAT=IOS) I-1, NOCOMP
    STOP
  END IF
40 CONTINUE

```

are used to read the component information cards by executing a DO loop for every component. Each component requires two to three cards depending on the number of points at which probabilities of kill are to be established. The READ statement sets a status indicator IOS to report the outcome of the READ operation. If IOS equals 0, the READ executed normally and the value of NOPNTS(I) is checked to insure that it is within the subscript range of the DEPTH and PKVAL arrays and that there are at least two elements. If the subscript number fails these criteria, an error message is printed and the program terminates. If NOPNTS(I) meets these conditions, an additional read is performed if more than four P(K/H) points are being entered so as to bypass this third component card. If IOS is greater than 0, an error occurred during one of the two possible reads. An error message is printed along with the values that were successfully read. The program then terminates. If IOS is less than 0, an unexpected end of file occurred. The program assumes that

too large a value of NOCOMP was entered, although a missing component card could cause the same effect. A message is printed and the program terminates.

The statements

```
REWIND (IRN)
DO 45 I = 1,5
  READ (IRN,1001)
45 CONTINUE
```

reset the formatted data file for reading. After setting the file pointer to the first record, the first five records are bypassed using a DO loop since they have been previously checked for content errors.

The next statements

```
DO 50 I = 1,NOCOMP
  READ (IRN,1001) (COMP(I),MAT(I),IFG(I),ITAH(I),IAHA(I),
    $  ITIT(I),THINFL(I),RHOF(I),IY(I),IU(I),NOPNTS(I),(DEPTH(J,I),
    $  PKVAL(J,I), J = 1,NOPNTS(I))
50 CONTINUE
```

are used to read the component information data by executing the DO loop once for every component. Each iteration of the loop causes the READ statement to read information on one component from two or three data cards, depending on the number of points for which probabilities are being entered. These data are stored in the component information arrays subscripted by I, the DO loop index.

The statements

```
READ (IRN,1000,END=60) NTMAX
READ (IRN,1002) (TIMAX(I),I=1,NTMAX)
60 CONTINUE
```

are used to read the optional shot line breakdown time intervals. If these data are not included, an end of data will be detected, which will cause a branch to Statement 60. Otherwise, the first READ statement will be used to accept the number of time bins and the second READ statement will be used to read each of the values for array TIMAX by executing an implied DO loop.

The statements

```
ELSE
  WRITE (IWR,2004) NOCOMP
  STOP
```

form the ELSE branch of the block IF when the number of components, NOCOMP, is too large. The WRITE statement prints an error message and then the program stops.

The statements

```
END IF
RETURN
```

close the block IF and return control to the calling program.

The last group of statements

```

100 FORMAT(/5X,'***** INPUT ERROR ***** FLUX =',E10.2/

END

```

is used to define all input and output formats required by this subroutine.

JTCG/AS-79-V-008

Intentionally Left Blank

SUBROUTINE READIN

This subroutine is used to read all input required for Program PRERD. This includes the flux distribution table, the component information cards, and, optionally, the time intervals for shot line breakdown. Subroutine READIN is also used to print the first page of PRERD output and to insure that certain input values are within valid ranges.

The statements

```

SUBROUTINE READIN
COMMON ICOMP(500),MAT(500),IFG(500),ITAB(500),IANA(500),
$      TIL,IT(500),NOPPTS(500),DEPTH(10,500),PKVAL(10,500),
$      PHOF(500),IIL(500),IY(500)
COMMON THINFL(500),NOCOMP
COMMON /LUNITS/ IRD,IWR
COMMON /SIZES/ ITC,IFX
DIMENSION FXCM(25),FTIM(25),TJMAX(25)

```

are used to declare array dimensions and enable transfer of information to and from this subroutine, using two labeled commons and one unlabeled common.

The statements

```

HEAD (IRD,1000) NOCOMP
IF (ITC .GE. NOCOMP+2) THEN
  READ (IRD,1000) IRVRS,CINCH
  HEAD (IRD,1001) IFMAX
  WRITE (IWR,2000) NOCOMP,IRVRS,CINCH
  IF ((IFMAX .LT. 1) .OR. (IFMAX .GT. IFX))
    WRITE (IWR,101) IFMAX
  WRITE (IWR,2001) IFMAX
  IF (IFMAX .GT. IFX) IFMAX = IFX

```

are used to read the number of target components and to insure that the number of components (plus two for default components) does not exceed the component array's dimensions, ITC. If this input error occurs, the ELSE branch of the block IF statement is executed where a warning message is printed and the program halts. This is the first of four fatal input errors that can be detected by Subroutine READIN. If the error does not occur, the subroutine continues by reading the shot line reverse flag, the input units conversion factor, and the number of points in the flux distribution table. This information is then echoed to device, IWR, in a formatted WRITE statement. If the number of points in the flux distribution, IFMAX, is negative or exceeds the array dimensions, an error message is printed but the subroutine continues by writing the heading for the flux table. The last IF statement insures that IFMAX is less than or equal to the flux array dimensions.

The next set of statements

```

HEAD (IRD,1002) (FXCM(I),I=1,IFMAX)
HEAD (IRD,1002) (FTIM(I),I=1,IFMAX)
TE = 0.
DO 110 I = 1,IFMAX
  TB = TE
  TF = FTIM(I)
  WRITE (IWR,2002) TB,TE,FXCM(I)
110 CONTINUE
TR = TE
TE = 1.E30
WRITE (IWR,2002) TM,TE,FXCM(IFMAX)

```

is used to read and write the flux distribution table. The flux levels apply to time intervals, TB to TE. Note that the subroutine prints one more point than it reads in the flux distribution. The last interval printed is an extra point and is used to indicate that the last flux level applies to all times greater than the last FTIM value.

The statements

```
DO 160 I = 1, IFMAX
  IF ((FXCM(I) .LE. 0.) .OR. (FXCM(I) .GT. 6.0E+04))
    WRITE (IWR,100) FXCM(I)
160 CONTINUE
```

are used to test each element of array FXCM to insure that the values are within the limits, 0.0 through 60000.0. If a flux level is outside of these bounds, an error message is printed but the subroutine continues.

The statements

```
DO 40 I = 1, NOCOMP
  READ (IRD,1001, IOSTAT=IOS) ICOMP(I), MAT(I), IFG(I), ITAR(I),
  IANA(I), TINIT(I), THINFL(I), RHOF(I), IV(I), IU(I), NOPNTS(I)
  IF (IOS .EQ. 0) THEN
    IF ((NOPNTS(I) .LE. 0) .OR. (NOPNTS(I) .GT. 10)) THEN
      WRITE (IWR,1010) I, NOPNTS(I)
      STOP
    ELSE IF (NOPNTS(I) .GT. 4) THEN
      READ (IRD,1001, IOSTAT=IOS)
    END IF
  END IF
  IF (IOS .GT. 0) THEN
    WRITE (IWR,1015) I
    WRITE (IWR,1001, IOSTAT=IOS) ICOMP(I), MAT(I), IFG(I), ITAR(I),
    IANA(I), TINIT(I), THINFL(I), RHOF(I), IV(I), IU(I), NOPNTS(I)
    STOP
  ELSE IF (IOS .LT. 0) THEN
    WRITE (IWR,1020, IOSTAT=IOS) I-1, NOCOMP
    NOCOMP = I - 1
  END IF
40 CONTINUE
```

are used to read the component information cards by executing a DO loop for every component. Each component requires two to three cards depending on the number of points at which probabilities of kill are to be established. The READ statement sets a status indicator IOS to report the outcome of the READ operation. If IOS equals 0, the READ executed normally and the value of NOPNTS(I) is checked to insure that it is within the subscript range of the DEPTH and PKVAL arrays. If the subscript is out of range, an error message is printed and the program terminates. This is the second fatal error detected by this subroutine. If NOPNTS(I) is within the array bounds 1 to 10, an additional read is performed if more than four P(K/H) points are being entered so as to bypass this third component card. If IOS is greater than 0, an error occurred during one of the two possible reads. An error message is printed along with the values that were successfully read. The program then terminates. This is the third fatal error detected by this subroutine. If IOS is less than 0, an unexpected end of file occurred. The program assumes that too large a value of NOCOMP was entered, although a missing component card could cause the same effect. A message is printed and execution continues after reducing the value of NOCOMP.

The statements

```

      REWIND (IRD)
      DO 45 I = 1,5
        READ(IRD,1001)
45    CONTINUE

```

reset the formatted data file for reading. After setting the file pointer to the first record, the first five records are bypassed using a DO loop since they have been previously checked for content errors.

The statements

```

      DO 50 I = 1,NCOMP
        READ (IRD,1001,IOSTAT=IOS) ICOMP(I),MAT(I),IFG(I),ITAR(I),
      $   IANA(I),IINT(I),THINFL(I),RHO(I),IV(I),IH(I),NOPNTS(I),
      $   (DEPTH(J,I),PKVAL(J,I),J = 1,NOPNTS(I))
50    CONTINUE

```

are used to read the component information cards by executing a DO loop for every component. These data are stored in several component information arrays which are defined at the end of this section in the List of Abbreviations and Symbols. The user may place the component information cards in any order so long as each component's continuation card(s) follow the initial card in the proper sequence.

The following statements

```

      READ (IRD,1000,END=60) NTMAX
      IF ((NTMAX .GE. 1) .AND. (NTMAX .LE. IFX)) THEN
        READ (IRD,1002) (TIMAX(I),I=1,NTMAX)
        WRITE (IWR,1005) (TIMAX(I),I=1,NTMAX)
        RETURN
      ELSE
        WRITE (IWR,102) NTMAX
        WRITE (IWR,1007)
        STOP
      END IF

```

are used to read the time intervals for shot line breakdown if the user includes this optional input. This is done by first reading NTMAX, the number of points in the time interval array. The value of NTMAX is then tested and if it is within the array limits, the subroutine reads and echoes to device IWR the upper boundary times for which Pk's and vulnerable areas are to be computed. Control then returns to the calling program. If NTMAX is outside the array bounds, an error message is printed and execution stops. This is the fourth fatal error detected by this subroutine. If the user omits the breakdown time intervals, the first READ statement detects an end of file condition on device IRD and branches to Statement 60.

The statements

```

      ELSE
        WRITE (IWR,1007)
        STOP
      END IF

```

are executed only if NOCOMP, the number of components, exceeds the array dimensions. These statements are used to print a warning message and stop program execution.

The statements

```
60 CONTINUE
  WRITE (IAR,1006)
  RETURN
```

are executed when the read statement following Statement 50 detects an end of file condition. In this event, the time intervals for the flux distribution will be used as the breakdown time intervals. The statements listed after Statement 60 are used to print this information in a warning message and then return control to the calling program.

The statements

```
100 FORMAT(/5X,"***** INPUT ERROR ***** FLUX =",E10.2)
101 FORMAT(/5X,"***** INPUT ERROR ***** IFMAX =",I10)
102 FORMAT(/5X,"***** INPUT ERROR ***** NTMAX =",I10)

END
```

are used to specify all formats for the READ and WRITE statements in this subroutine and to end this program unit.

SUBROUTINE REVRSE

When using the QKLOOK programs, a user may obtain data for a second view without generating a new binary LOS file. This is done by setting the shot line reverse flag, IRVRS, on the second QKPK input data card equal to 1. This will cause Program QKPK to call Subroutine REVRSE for every shot line in the viewing plane. This subroutine is used to reverse the order of the component encounters along the shot line and to transform the shot line coordinates to the new system. The resulting shot line is the same as the original one but in the opposite direction. Note that LOS data from Program MAGIC does not include exit obliquity angles. If MAGIC data is used, the obliquity angles on the reversed shot line are set equal to the original obliquity angles.

The statements

```

SUBROUTINE REVRSE(J)
COMMON ICOMP(500),MAT(500),IFG(500),ITAB(500),IANA(500),
$      T1,I1(500),NUMPTS(500),DEPTH(10,500),PRVAL(10,500),
$      MMUF(500),IRVRS,IU(500),IV(500)
COMMON THINFL(500),SH(2,170),JH(5,170),CINCH
COMMON /TWO/ XLOS(100),JHT(100),NENC,UBU(100)

```

are used to specify COMMON blocks and one argument, which are required for transfer of information to and from this subroutine. The SH array is the only one required from the unlabeled COMMON block. COMMON /TWO/ contains the number of encounters NENC, and the encounter arrays which will be reversed by this subroutine. The argument J is the shot line index needed as a subscript for array SH.

The statement

```
SH(1,J) = -SH(1,J)
```

is used to reflect the y-coordinate of the shot line about the Z-axis while the z-coordinate of the shot line remains the same.

The next statements

```

DO 30 N = 1,NENC/2
  JJ = NENC - N + 1
  J1 = JHT(N)
  S1 = OBU(N)
  S2 = XLOS(N)
  JHT(N) = JHT(JJ)
  OBU(N) = OBU(JJ)
  XLOS(N) = XLOS(JJ)
  JHT(JJ) = J1
  OBU(JJ) = S1
  XLOS(JJ) = S2
30 CONTINUE
RETURN
END

```

are used to reverse the order of the components along the shot line. There are three encounter information arrays which must be interchanged. The DO loop is used to execute the interchange NENC/2 times. The variable JJ is computed in the first assignment statement and is the subscript of the array element to be interchanged with the Nth array element. The last nine assignment statements in the DO loop are used to interchange the Nth and JJth elements in the three encounter information arrays.

SUBROUTINE TABLE

This subroutine is called by Subroutine RAT and is used to compute a penetration rate for an encounter with a nonmetallic component using a table look-up procedure. The table look-up code is defined by the user in the formatted component information data.

The first set of statements

```

SUBROUTINE TABLE
COMMON ICOMP(500),MAT(500),IFG(500),ITAB(500),IANA(500),
$ TINIT(500),NUPNTS(500),DEPTH(10,500),PKVAL(10,500),
$ KHUF(500),IRVNS,IU(500),IY(500)
COMMON THINFL(500),SH(2,170),JH(5,170),CINCH
COMMON /ONE/ NOCOMP,FLX,IFLAG,PEAKF,NCRIT
COMMON /PROP/ ALP,KHU,CP,TMLT,XLAMBD,RATE,JCUMP,J,OP,XK,TVAP,
$ CPL,ITER,T
COMMON /LUNITS/ IRD,IWR,IIN,IOUT

```

is used to facilitate transfer of data to and from this subroutine and to declare array dimensions. The ITAB array in the unlabeled COMMON contains the table look-up codes. The variable FLX in COMMON /ONE/ is the flux level for this rate computation. COMMON /PROP/ contains the variable, J, which is the component index used for the table look-up code, and the variable, RATE, which is the penetration rate computed in Subroutine TABLE.

The statements

```

C      IF (ITAB(J) .EQ. 1) THEN
C
C          PLEXIGLASS
C
C          RATE = 4.35E-10 * FLX * 0.9
C      ELSE IF (ITAB(J) .EQ. 2) THEN
C
C          TRIPLEX DIELECTRIC
C
C          RATE = 2.6822E-10 * FLX * 0.9
C      ELSE IF (ITAB(J) .EQ. 3) THEN
C
C          FIBRITE
C
C          RATE = 2.633E-10 * FLX * 0.9
C      ELSE IF (ITAB(J) .EQ. 4) THEN
C
C          RUBBER
C
C          RATE = 2.6909E-10 * FLX * 0.9
C      ELSE IF (ITAB(J) .EQ. 5) THEN
C
C          GLASS
C
C          RATE = .35E-10 * FLX * 0.9
C      ELSE IF (ITAB(J) .EQ. 6) THEN
C
C          FIBER GLASS
C
C          RATE = .94E-10 * FLX * 0.9

```

are part of an IF block which takes the appropriate action based on the value of the table look-up code, where ITAB(J) is the table look-up code for the component being encountered. For acceptable values, the penetration rate for the material specified, is computed as a product of the material coefficient, the flux level FLX, and an absorption factor of 0.9. This is written

mathematically as:

$$R = 0.9CF$$

(3-1)

The next statements

```

      ELSE IF (ITAB(J) .EQ. 7) THEN
C
C      PYROCERAM
C
      IF (FLX .GT. 3.74E+6) THEN
        RATE = -1.4E-4 + 3.74E-11 * FLX * 0.9
      ELSE
        WRITE (IWR,2000)
        STOP
      END IF

```

are used to compute the penetration rate when the table look-up code equals 7₂. For this table look-up code, the flux level must be greater than 374 watts/cm². When the flux level is high enough, the assignment statement in the THEN branch of the IF block is used to compute the penetration rate. Otherwise, the ELSE branch prints a fatal error message and the program terminates.

The statements

```

      ELSE IF (ITAB(J) .EQ. 8) THEN
C
C      GLASS FIBER EPOXY
C
        RATE = 0.556E-10 * FLX * 0.9
      ELSE IF (ITAB(J) .EQ. 9) THEN
C
C      GRAPHITE EPOXY
C
        RATE = 0.119E-10 * FLX * 0.9

```

are used to compute the penetration rate when the table look-up code equals 8 or 9.

The statements

```

      ELSE
        RATE = 0.0
        WRITE (IWR,1000) JCUMP,ITAB(J)
      END IF
      RETURN

```

are used to assign a penetration rate equal to 0.0 and to write a warning message when the table look-up code does not have an acceptable value. The END IF statement closes the block IF and the RETURN statement returns control to Subroutine RAT.

The final group of statements

```

1000 FORMAT(' THIS COMPONENT DOES NOT FIT THE BOUNDS FOR TABLES',216)
2000 FORMAT(' THE FLUX IS INDICATED TO BE LESS THAN 374 W/CM**2/'
          & 'CHECK SUBROUTINE TABLE...PROGRAM HALTING')
      END

```

is used to define the formats for the error message output and to end Subroutine TABLE.

PEAKF	---	Weapon intensity, flux	watts/cm ²
PKNBR	---	Maximum number of penetration depths and Pk values that can be specified for each component; the first dimension of the DEPTH and PKVAL arrays	---
PKTIME(1,I) I≤200	---	y-coordinate in the viewing plane for each new shot line; otherwise, the time needed to penetrate from the start of the shot line to the depth DEPTH(1,I) in the encounter with component number Il(I)	inches or seconds
PKTIME(2,I) I≤200	---	z-coordinate in the viewing plane for each new shot line; otherwise, the time needed to penetrate from the start of the shot line to the depth DEPTH(2,I) in the encounter with component number Il(I)	inches or seconds
PKTIME(J,I) J≤10, I≤200	---	Time needed to penetrate from the start of the shot line to the depth DEPTH(J,I) in the encounter with component number Il(I)	seconds
PKVAL(J,I) J≤10, I≤200	Pk _N	Pk associated with penetration to a specified depth for the Ith component	---
PLS(I) I≤200	---	Equals zero for each new shot line; otherwise, the time needed to penetrate from the start of the shot line through the LOS thickness of component number Il(I)	--- or seconds
RADEXP	---	Unused variable, read on first record of the LOS file	---

LIST OF ABBREVIATIONS AND SYMBOLS
(SIMULATION MODEL)

Program QKPK (Continued)

Abbreviation or Symbol	Equivalent in Mathematical Model	Definition	Units
RATE	R	Penetration rate of a Directed High Energy Weapon against a component	m/sec
RATES(I) I $\leq$ 100	---	Penetration rate for the Ith shot line encounter in Sub- routine RAT (equivalent to RATES(I,J) for Jth flux level in Program QKPK)	m/sec
RATES(I,J) I $\leq$ 100, J $\leq$ 25	---	Penetration rate for the Ith shot line encounter at the Jth level in the flux dis- tribution	m/sec
RBAR	---	Average penetration rate for complete perforation of a specific component	m/sec
RHO	ρ	Component material density	kgm/m ³
RHOF(I) I $\leq$ 500	---	Density factor (0 $\leq$ RHOF $\leq$ 1) for the Ith component; used to compute the actual component LOS thickness for components not modeled in the influence mode	---
RHX	---	Component material density	kgm/m ³
SH(1,J) J $\leq$ 170	---	Shot line y-coordinate in the viewing plane	varies
SH(2,J) J $\leq$ 170	---	Shot line z-coordinate in the viewing plane	varies
SPECIF(I,1,K) I $\leq$ 11, 2 $\leq$ K $\leq$ 10	---	Specific heat for the Ith material code at the Kth temperature argument	joules/ kgm °C
STAR	---	Maximum energy absorption rate for an encounter in which the surface temperature exceeds the vapor temperature	watts/m ²

Card: C4

PROGRAM PEAKAY INPUT

Program PEAKAY requires two input files. A short formatted file with the time interval at which vulnerable areas are to be computed is read from Logical Unit Number 5. A binary penetration times file, which is the output of Program QKPK, is read from Logical Unit Number 2. The user must assemble the formatted input file.

PEAKAY Formatted Data Deck

This deck contains two cards; the first contains the number of time intervals and a component vulnerability area flag. The second contains the upper boundaries of the time intervals. There must be no more than 10 time intervals. The vulnerability area flag determines whether the vulnerable areas computed for the components are true values (flag = 1) or incremental values (flag = 0). The first time interval is assumed to start at time 0.00. All other time intervals begin when the preceding interval ends. The times on the second card must be in ascending order. Figure 5-2 shows the PEAKAY data deck setup using cards PK1 and PK2.

FIGURE 5-2. PEAKAY Data Deck Setup.

Number of Time Intervals					Card: PK1
ID	Parameter	Units	Format	Columns	Description
A	NTIME	---	I5	1-5	The number of time intervals for which kill probabilities and vulnerable areas are to be computed. NTIME must be less than or equal to 10.
B	AVFLAG	---	I5	6-10	Flag indicating whether the component vulnerable areas are to be calculated as incremental or true 0 = incremental values 1 = true values

Card: PK1

Time Interval Boundaries										Card: PK2	
		A	B	C	D	E	F	G	H	I	J
ID	Parameter	Units	Format	Columns	Description						
A	TIMES(1)	seconds	F8.2	1-8	Upper boundary of the first time interval for which PK's and vulnerable areas are to be computed.						
B	TIMES(2)	seconds	F8.2	9-16	Upper boundary of the second time interval for which PK's and vulnerable areas are to be computed.						
.	.	.	.	.	.						
.	.	.	.	.	.						
.	.	.	.	.	.						
.	TIMES (NTIME)	seconds	F8.2		Upper boundary of the last time interval for which PK's and vulnerable areas are to be computed.						
Note: The lower boundary for the first interval is 0.00. The lower boundary for all other intervals equals the upper boundary of the preceding interval. $NTIME \leq 10$.											
Card: PK2											

PEAKAY Binary Input File

The penetration times for each encounter along each shot line are read from the PEAKAY binary input file. These data are the output of Program QKPK. The records vary in length and the total number of records depends on the amount of data. There are three types of records on this file.

Viewing Plane Description

Figure 5-3 shows the format for the first record of the binary file which contains nine words. The data on this record include the attack aspect angles, grid size, minimum and maximum shot line coordinates, and the number of components in the target model.

Component Data and Flux Distribution

This is the second record on the file and it contains four arrays of component information, the shot line reverse flag, the number of flux distribution points, and the time and flux values from the flux distribution. It has $4 \times \text{NOCOMP} + 2 + 2 \times \text{IFMAX}$ words. Figure 5-4 lists the parameters and definitions on this record.

Penetration Times

Figure 5-5 shows the format for the third and all subsequent records on this file. It contains three arrays with 2400 total words per record. The second subscript of the first array corresponds to the subscripts of the other two arrays. They define either a shot line or an encounter along a shot line. When the value of an element of the fourth array, I1, equals 9999, the end of all data for the view is indicated and the rest of the data on the binary input file is not processed.

FIGURE 5-3. PEAKAY Binary Input, Viewing Plane Description.

Record Number	1	2	3	...	Last

		---	Equals 9999 to indicate the end of view

FIGURE 5-5. PEAKAY Binary Input, Penetration Times (Page 4 of 4).

PROGRAM PRERD INPUT

One formatted deck is the only input necessary for Program PRERD. It is read from Logical Unit Number 5 during execution of Subroutine READIN. The data on these cards must be assembled by the user and are very important in order to obtain good results from QKLOOK. The importance and complexity of these data are the reasons that Program PRERD must be used. It will flag possible errors in this data deck so that the user can correct errors before executing Program QKPK which reads the same deck. Figure 5-6 shows the data deck setup with the eight types of cards in this deck.

Number of Components

This is the first card in the deck and contains the number of components in the target model. The array dimensions currently allow a maximum of 498 components.

Reverse Flag and Conversion Factor

This is the second card in the deck and contains the shot line reverse flag and a length units conversion factor. The reverse flag enables a user to obtain data from the view used by the shot line generating program or the opposite view without a second execution of the shot line generating program. When the shot lines are being reversed using data from Program MAGIC, the new entrance obliquity angles equal the old entrance obliquity angles, because Program MAGIC output does not include exit obliquity angles. The length conversion factor allows the input lengths to be in any one unit of measure. The data card description lists the input variables from both files which are converted using CINCH.

Number of Flux Distribution Points

The third data card contains the number of points in the flux distribution table which is on card types QK4 and QK5. The current program allows a maximum of 25 flux distribution points.

Flux Levels

This card type is fourth in the data deck and contains the weapon flux levels at each point in the flux distribution. Flux levels must be greater than 0.00 and less than or equal to 60000.0 watts/cm². There will be one, two, or three of these cards consecutively depending on the number of flux points, IFMAX.

FIGURE 5-6. Program PRERD Data Deck Setup.

Flux Time Intervals

One, two, or three of these cards, depending on IFMAX, follow the flux levels in the data deck. The times in the flux distribution are listed on these cards. These times correspond by subscript with the flux levels on card type QK4.

Component Information

Cards QK6 and QK6A are included for every component in the target model, NOCOMP. QK6B is included for a component when more than four penetration depths and associated Pk's are to be entered. The component identification numbers must correspond to component numbers used in the target model for the shot line generating program. The order of the components in the deck can vary, because Subroutine FSORT is used to sort these data into ascending order by component number.

Number of Shot Line Time Intervals

Card QK7 contains the number of time intervals for shot line breakdown by times required to reach maximum shot line Pk. This and the last card type (QK7 and QK8) are optional input. If cards QK7 and QK8 are not included, the values from cards QK3 and QK5 will be used as default data. If card QK7 is included, then card QK8 is required.

Shot Line Time Intervals

This card type contains the time intervals for shot line breakdown by times required to reach maximum shot line Pk. One time is listed for each time interval. The beginning time for each interval is assumed to equal the ending time of the preceding interval. The first time interval begins at time 0.00. There are one, two, or three of these cards depending on the number of intervals, NTMAX. Card type QK8 may be excluded from the deck if card QK7 is also excluded. In this case, the times on card QK5 will be used as default data.

Number of Components					Card: QK1

*Any one length unit may be used for these. They are converted by using the factor CINCH.

FIGURE 5-7. Program QKPK Data Deck Setup.

QKPK Binary Input File

This file contains encounter information for each encounter along each shot line from one viewing plane. It may be the output from Program CONMAG (converts MAGIC to QKLOOK format), FASTGEN, or possibly another shot line generating program. The order of data on this file must match the order described in Figures 5-8 and 5-9 in order to execute Program QKPK. Some shot line generating programs may produce data for more than one view. Program QKPK halts after processing one view, so this discussion will assume the record containing the first end-of-view flag, is the end of the input file. The units for some of the parameters in this file are described as "varies" on the record description forms. These are the parameters which are converted using CINCH, the conversion factor from card QK2 in the QKPK formatted data deck.

Viewing Plane Description

This is always the first record for a view and is described in Figure 5-8. It contains nine parameters which define the attack angles, grid size, and minimum and maximum shot line coordinates for all shot lines in the viewing plane.

Encounter Data

Figure 5-9 depicts the data arrangement for the second and all subsequent records on this binary file. These data describe each encounter along each shot line. The shot line coordinates are duplicated when a shot line has more than one encounter. The last encounter for a shot line is indicated when JH(1,J) equals 9. If the encountered component number JH(2,J) equals 0, this marks the end of all data for the view, and all subsequent values on the record are ignored. The record containing the end-of-view flag is also the last record read from the binary input file.

ARRAY DIMENSIONS ARE TOO SMALL...PROGRAM HALTING

FIGURE 6-36. Program PRERD Output, Error Message (NOCOMP>498).

PROGRAM QKPK OUTPUT

Execution of Program QKPK produces two output files. Formatted output is printed on Logical Unit Number 6. Figures 6-37 through 6-41 are examples of the formatted output that is generated during a normal execution of Program QKPK. Figures 6-42 through 6-47 are examples of error messages which may be printed during program execution. A binary file containing penetration times for each encounter is written on Logical Unit Number 2. Figures 6-48 through 6-50 display the formats for each record on the binary file.

QKPK Printed Output

The first page of QKPK printed output, Figure 6-37, lists the number of components, shot line reverse flag, input lengths conversion factor, and the flux distribution table. The times in the flux table are in seconds and the flux levels are in watts per square centimeter. This page is printed during execution of Subroutine RDATA.

Figure 6-38 is an example of the second page of QKPK formatted output. It is printed during execution of Program QKPK after the component information arrays have been sorted into ascending order. The first ten columns correspond to the parameters on cards QK6, QK6A, and QK6B from the QKPK data deck. The column labeled "CRD" gives the component subscript number in the component identification number array. This number is used to identify components in the QKPK binary output file.

The type of output shown in Figure 6-39 is printed only if the value of the flag IECHO is set to a value other than zero. These data are a complete copy of the binary output file and may fill several pages of printout. Figures 6-48 through 6-50 contain definitions for those parameters appearing in the binary output file.

Figure 6-40 is an example of the next page of QKPK output which shows the number of critical shot lines that reach their maximum Pk during each time interval. The time intervals are those specified on cards QK8 in the QKPK data deck. The times in the table are expressed in seconds and the flux levels are expressed in watts per square centimeter. The last time interval represents the value for all times greater than the last start time. Only critical shot lines are included in the breakdown. A critical shot line must encounter at least one critical component.

An example of the last page of QKPK output is shown in Figure 6-41. WRITE statements in the Main program unit are used to print this page. It lists any components in an encounter whose LOS thickness is less than either DEPTH(1) or DEPTH(NOPNTS). If the thickness is less than DEPTH(1), the encounter Pk is 0.00. If thickness is less than DEPTH(NOPNTS), the Pk is less than 1.00. However, a thickness equal to DEPTH(NOPNTS) may or may not equal 1.00; this depends on the value assigned to PKVAL(NOPNTS). Entries in this list indicate possible errors in the selection of DEPTH values.

Figure 6-42 presents the fatal error message printed during execution of Subroutine RDATA whenever the number of components in the target model (QKPK) data deck) exceeds array dimensions. The current program has a limit of 498 components.

The fatal error message shown as Figure 6-43 is also printed during Subroutine RDATA execution. This error occurs whenever a flux level less than or equal to 0.0 or greater than 60000.0 watts per square centimeter is entered from the data card deck.

Figure 6-44 contains a warning message printed whenever an encountered component number from the LOS file has no match in the component information arrays. This warning message is printed during execution of Subroutine BSRCH. When components are included in the target model for the shot line generating program but not in the QKPK data deck, default component characteristics are assigned as follows:

1. Components with identification numbers less than 1000 default to a 2024 AL noncritical component with no warning message printed.
2. Components with identification numbers between 1000 and 6999 or greater than 8000 default to a 7075 AL noncritical component with a warning message printed as shown in Figure 6-44.
3. Components with identification numbers between 7000 and 7999 default to a 7075 AL noncritical component with no warning message printed.

Figure 6-45 shows a non-fatal error message printed whenever Subroutine TABLE is invoked for a component whose table look-up code is less than or equal to 0 or greater than 9. A penetration rate equal to 0.00 is assigned and control of execution returns to Subroutine RATE. The warning message includes the component number and the erroneous table look-up code.

Figure 6-46 shows a fatal error message which is printed during Subroutine TABLE execution. This error occurs when a component has a table look-up code equal to 7 and a weapon flux level less than 374.0 watts per square centimeter.

If the Main QKPK program unit detects a shot line with more than 100 encounters, an error message (Figure 6-47) is printed and program execution stops. This prevents bounds violations in the encounter data arrays.

QKPK Binary Output

Parameters and their definitions for each record of the binary penetration times file are listed on Figures 6-48 through 6-50. The first record contains nine parameter values and describes the viewing plane. The second record contains values for the component information arrays, the shot line reverse flag, and the flux distribution table. The third and all subsequent records contain the encounter penetration times. The last record on this file contains an end-of-view flag, parameter I1 equal to 9999. This file is used as the binary input file for Program PEAKAY.

```

THIS SUBROUTINE IS ENTERED WITH THE NECESSARY INFO FOR ONE SHOT LINE. ENERGY IS PASSED ALONG THIS SHOT LINE FOR ALL TIME DURATIONS DESIRED, STARTING WITH THE SHORTEST. A TIME HISTORY IS KEPT SO THAT FOR EACH SUCCESSIVE TIME IT IS NECESSARY ONLY TO PENETRATE THOSE COMPONENTS NOT PREVIOUSLY BREACHED BY SHORTER TIMES.

PKTIME(1) IS THE TIME NEEDED TO REACH PK-MIN FOR THIS COMPONENT, STARTING FROM THE BEGINNING OF THE SHOT LINE.

PKTIME(I) IS THE TIME NEEDED TO REACH AN INTERMEDIATE PK FOR THIS COMPONENT, STARTING FROM THE BEGINNING OF THE SHOT LINE. (I IS IN THE INTERVAL (1,N-1)).

PKTIME(N) IS THE TIME NEEDED TO REACH PK-MAX FOR THIS COMPONENT, STARTING FROM THE BEGINNING OF THE SHOT LINE. (N IS IN THE INTERVAL (2,10)).

PLS IS THE TIME NEEDED TO PERFORATE THIS COMPONENT, STARTING FROM THE BEGINNING OF THE SHOT LINE.

TREG IS THE LOWER BOUND OF THE TIME INTERVAL (I.E., IT REPRESENTS THE TIME ALREADY USED UP)

TEND IS THE DURATION TIME FROM ARRAY TIMES WHICH IS CURRENTLY BEING PROCESSED.

PK1 IS THE TIME AT WHICH THE MAXIMUM POSSIBLE PK FOR THIS COMPONENT WILL BE ACHIEVED. (NOTE PK=1.0 MAY NOT BE POSSIBLE SINCE PLS MAY BE LESS THAN PKTIME(N) OR PKVAL(N) MAY BE LESS THAN 1.0).

PK2 IS THE MINIMUM TIME NEEDED TO GET A NON-ZERO PK FOR THIS COMPONENT IN THE INTERVAL TREG TO TEND.

PK3 IS THE TIME NEEDED TO GET MAXIMUM PK FOR THIS COMPONENT IN THE INTERVAL TREG TO TEND.

PKX = 0.

SUBROUTINE ASPTOIND

This subroutine is used to correlate each of the standard 26 viewing angles used by programs like FASTGEN with an index used by the program ASALT. Each of the standard azimuth-elevation angle pairs has a correspondence to one of 26 ASALT indices. The subroutine is called by the main program.

The first set of statements

```
SUBROUTINE ASPTOIND(AZ,EL,ILOOK)
  INTEGER AZIX
  INTEGER ELIX
```

is used to pass three arguments, AZ, EL, and ILOOK, and to declare AZIX and ELIX to be integers. AZ and EL are the FASTGEN azimuth and elevation angles and ILOOK is the corresponding ASALT index.

The next statements

```
IF (ABS(EL-90.) .LE. 1.E-05) THEN
  ILOOK = 26
ELSE IF (ABS(EL+90.) .LE. 1.E-05) THEN
  ILOOK = 1
```

test for a top or bottom view. The block IF first checks for an elevation angle of 90 degrees, implying a top view. If this angle is found, the ASALT index is set to 26. Otherwise, a check for a bottom view with an elevation angle of -90 is made. If this test is successful, the ASALT index is set to 1; otherwise, the block IF continues with the ELSE branch where checks are made for the other 24 viewing angles.

The statements

```
ELSE
  ELIX = 0
  CHK = -45.
  DO 10 I = 1,3
    IF (ABS(EL-CHK) .GT. 1.E-05) THEN
      CHK = CHK + 45.
      ELIX = ELIX + 8
    END IF
  10 CONTINUE
```

check for a standard elevation and set an elevation index accordingly. The first two assignment statements initialize the angle to be checked and the elevation index. The DO loop checks for the remaining three valid elevation angles. If the elevation angle and the checking angle are not equal within roundoff limits, the checking angle, CHK, is incremented by 45 degrees and the elevation index, ELIX, is incremented by 8.

The following statements

```
IF (CHK .LT. 50.) THEN
  CHK = 0.0
  IF (AZ .LT. 180.) THEN
    AZIX = 6
  ELSE
    AZIX = 2
    AZ = AZ - 180.
  END IF
```

are used in preparation for determining the azimuth angle. The first IF statement checks to determine if a standard elevation angle was found. If not, the ELSE branch of the block IF is executed. Otherwise, the THEN branch sets the azimuth checking angle to 0.0. The second IF statement determines whether the azimuth in question is less than 180 degrees. If so, the azimuth index is set to 2 and the azimuth is adjusted so as to be less than 180 degrees.

The statements

```

DO 30 I = 1,4
  IF (ABS(AZ-CHK) .GT. 1.E-05) THEN
    CHK = CHK + 45.
    AZIX = AZIX + 1
  END IF
30 CONTINUE

```

form a DO loop to check for a standard azimuth angle. The statements in the IF block are executed when the azimuth value does not equal the checking angle within roundoff limits. In this case, the checking angle is incremented by 45 degrees and the azimuth index is incremented.

The next statements

```

IF (CHK .LT. 140) THEN
  ILOOK = ELIX + AZIX
ELSE
  WRITE (6,901) AZ, EL
END IF

```

form a block IF to take the appropriate action depending on whether a standard azimuth is present. If a standard azimuth is found, the THEN branch is executed and the ASALT index is the sum of the elevation and azimuth indices. If not, an error message is printed.

The statements

```

ELSE
  WRITE (6,901) AZ, EL
END IF
END IF

```

are executed when a standard elevation is not found. The WRITE statement prints an error message. The two END IF statements close the IF block for determining whether a valid elevation is found and for ascertaining whether a top, bottom, or other view is present.

The statements

```

RETURN
901 FORMAT (' *** ERROR *** CANNOT CLASSIFY LOOKANGLES AZ, EL' /
$         15X,2F10.2)
END

```

return control to the calling program, define the error message format, and end the subroutine.

SUBROUTINE FINDCOMP

This subroutine is used to search an array containing critical component numbers for a specific component. If the number is found, the array element index is returned. If not, a zero is returned. This subroutine is called by the Subroutine GETXYZ.

The first set of statements

```
SUBROUTINE FINDCOMP(IPT,ICOMP,IC,NCRIT)
DIMENSION ICOMP(100)
IPT = 0
I = 0
```

is used to pass four arguments, IPT, ICOMP, IC, and NCRIT. IPT is the element of the array containing the desired component number or zero if the component is not in the array. ICOMP is the array containing critical component numbers. IC is the component number being sought and NCRIT is the number of critical components in ICOMP. The DIMENSION statement declares ICOMP to be an array. The two assignment statements initialize the returned element number and a search index to zero.

The statements

```
100 CONTINUE
  I = I + 1
  IF (ICOMP(I) .EQ. IC) IPT = I
  IF ((I .GE. IPT) .AND. (I .LT. NCRIT)) GO TO 100
  RETURN
END
```

search the ICOMP array for the desired component number and return control to the calling subroutine when the search is completed. The first four statements form a "REPEAT UNTIL" loop. Statement 100 forms the beginning of the loop. The assignment statement increments the index of the component array. The IF statement checks if the current element in the array matches the sought after component. If so, IPT is set to the index of the current element. The conditional GO TO statement checks whether the desired component has been found and whether the array has been completely searched. If both of these conditions are false, a branch is made to examine the next element. If either condition is true, control returns to the calling program unit.

SUBROUTINE GETXYZ

This subroutine is used to compute the locations of critical components in the ASALT aircraft coordinate system. It obtains these coordinates by averaging the shot line coordinates that intersect the components from the front, side, and bottom views. This subroutine is called by the main program.

The statements

```
SUBROUTINE GETXYZ(ICOMP,COMP,NCRIT,NAME)
CHARACTER*8 NAME(100)
DIMENSION ICOMP(100),COMP(3,100)
DIMENSION SH(2,170),JH(5,170),AZV(3),ELV(3)
DIMENSION X(100),Y(100),Z(100)
DIMENSION NX(100),NY(100),NZ(100)
DATA AZV /0.0,90.0,90.0/, ELV /0.0,0.0,-90.0/
DATA X /100*0.0/, Y /100*0.0/, Z /100*0.0/
DATA NX /100*0/, NY /100*0/, NZ /100*0/
```

are used to pass four arguments, ICOMP, COMP, NCRIT, and NAME, to declare array dimensions, and to set initial values. ICOMP is the array containing critical component numbers. COMP is an array to hold the ASALT aircraft coordinates of the critical components. NCRIT is the number of critical components. NAME is an array used to hold the names of the critical components. SH contains the shotline y- and z-coordinates that intersect the components. JH holds the component numbers or a flag indicating the end of the view. AZV and ELV indicate the azimuth and elevations used to define the three views: front, side, and bottom. X, Y, and Z are the ASALT aircraft coordinates for each critical component. NX, NY, and NZ count the number of times that each component is described using x-, y-, or z-coordinates (only two of the three coordinates are used in each viewing plane).

The statements

```
DO 150 ILOS = 1,3
  READ (ILOS) AZ, EL
  IF ((AZ .EQ. AZV(ILOS)) .AND. (EL .EQ. ELV(ILOS))) THEN
```

are used to obtain line of sight data for the three viewing planes. The DO loop is used to read the data from each plane and to start the conversion of the coordinates to the ASALT aircraft system. The READ statement is used to get the azimuth and elevation for the current view plane. The IF statement determines if the current view plane is the standard plane that the program expects. If so, the THEN branch of the IF block is executed; otherwise the ELSE branch is executed.

The statements

```
20  READ (ILOS, END=150) (DUM,(SH(I,J),I=1,2),(JH(I,J),I=1,5),
  $    J=1,170)
  DO 100 J = 1,170
    IF (JH(2,J) .EQ. 0) GO TO 150
    SY = SH(1,J)
    SZ = SH(2,J)
    IC = JH(2,J)
    CALL FINDCOMP(IPT,ICOMP,IC,NCRIT)
```

are used to read the line of sight data and to set up for the conversion of coordinates. The READ statement forms the first statement in a "REPEAT

UNTIL" loop. The READ obtains a block of data at a time. The loop will continue executing until all the shot line data for the view have been processed. The DO loop is used to convert the shot line coordinates from the data block obtained by the READ statement. The IF statement determines if the end of the view has been reached. If so, a branch to Statement 150 is made to permit the processing of any other views. This is the exit from the "REPEAT UNTIL" loop. The next three assignment statements get the shotline y-coordinate, z-coordinate, and component number. The CALL statement returns the index of the ICOMP array containing the component if the component is critical or a zero if the component is noncritical.

The statements

```

      IF (IPT .NE. 0) THEN
        IF (ILOS .EQ. 1) THEN
          Y(IPT) = Y(IPT) + SY
          NY(IPT) = NY(IPT) + 1
          Z(IPT) = Z(IPT) + SZ
          NZ(IPT) = NZ(IPT) + 1
        ELSE IF (ILOS .EQ. 2) THEN
          X(IPT) = X(IPT) - SY
          NX(IPT) = NX(IPT) + 1
          Z(IPT) = Z(IPT) + SZ
          NZ(IPT) = NZ(IPT) + 1
        ELSE
          X(IPT) = X(IPT) - SY
          NX(IPT) = NX(IPT) + 1
          Y(IPT) = Y(IPT) + SZ
          NY(IPT) = NY(IPT) + 1
        END IF
      END IF
100   CONTINUE
      GO TO 20

```

are used to convert the shot line coordinates for critical components. The first IF block is executed only when a critical component is encountered. This block contains another IF block whose branches are executed depending upon whether the front, side, or bottom view is being processed. In each case, the shot line coordinates are added to or subtracted from the appropriate aircraft coordinates and a count for each addition/subtraction is kept. Statement 100 following the two IF blocks ends the DO loop which processes the shot line data block. The GO TO statement forms the end of the "REPEAT UNTIL" loop.

The following statements

```

      ELSE
        WRITE (6,11) ILOS,AZ,EL
        STOP
      END IF
150 CONTINUE

```

are the remaining statements in the viewing plane processing loop. The ELSE statement begins the branch of the block IF that is executed when a standard viewing plane is not found. The WRITE statement prints an error message and the STOP statement terminates the program. The END IF statement closes the IF block and Statement 150 concludes the view plane processing loop.

The next statements

```

WRITE (6,301) NCRIT
DO 300 I = 1,NCRIT
  IF (NX(I) .NE. 0) COMP(1,I) = X(I) / FLOAT(NX(I)) * 0.0254
  IF (NY(I) .NE. 0) COMP(2,I) = Y(I) / FLOAT(NY(I)) * 0.0254
  IF (NZ(I) .NE. 0) COMP(3,I) = Z(I) / FLOAT(NZ(I)) * 0.0254

```

```

      WRITE (6,302) I,NAME(I),ICOMP(I),COMP(1,I),NX(I), COMP(2,I),
      $      NY(I),COMP(3,I),NZ(I)
300 CONTINUE

```

are used to complete the calculation of the ASALT aircraft coordinates and to print these values out. The first WRITE statement prints the page header. The DO loop is used to calculate the average ASALT aircraft coordinates for each critical component and send these values to the output device. The three IF statements find the average x-, y-, and z-coordinate in meters. The next WRITE statement prints the coordinate values. Statement 300 closes the DO loop.

The final set of statements

```

      RETURN
11  FORMAT (' ***ERROR***  INCORRECT LOS FILE FOR VIEW',I3,
      $      '  AZ=',F8.1,'  EL=',F8.1)
301  FORMAT ('1',22X,'--',I3,' CRITICAL COMPONENT LOCATIONS --'/
      $      '0 + + + COMPONENT + + +'/
      $      '  INDEX  NAME      NUMBER',6X,'X-COORD. SAMPLE',
      $      6X,'Y-COORD. SAMPLE',6X,'Z-COORD. SAMPLE')
302  FORMAT (1X,I4,3X,A8,I6,1X,3(F12.2,I7,2X))
      END

```

returns control to the calling program and provides the formats for the messages that are output.

SUBROUTINE NAMES

This subroutine is used to read names of components from an input file. If the input file is empty, blanks are entered for the names. The subroutine is called by the main program.

The first statements

```
SUBROUTINE NAMES(NAME,NCRIT)
CHARACTER*8 NAME(100)
```

are used to pass two arguments, NAME and NCRIT. NAME is an array to hold the names of the critical components and NCRIT is the number of critical components. NAME is declared to be an array of character strings of length 8.

The statements

```
READ (7,120,END=100) (NAME(I),I=1,NCRIT)
RETURN
```

attempt to read the names of the critical components from an input file. If the read completes successfully, control is returned to the calling program. If an end of file is encountered, the execution branches to Statement 100.

The next statements

```
100 DO 110 I = 1,NCRIT
    NAME(I) = '
110 CONTINUE
    RETURN
120 FORMAT (4A)
END
```

are used when an end of file occurs. The DO loop is executed to initialize the component names to a string of blanks. Control is then returned to the calling program.

PROGRAM VAMERGE

This program is used to produce one of the two input files required by the ASALT-I Model in assessing survivability against laser threats. This program reads the vulnerable area files created by the QKLOOK program PEAKAY, averages the component Pk's, and prints them in the ASALT input format.

The first set of statements

```
PROGRAM VAMERGE
PARAMETER (TDEL = 0.5, IPRINT = 2, LINLIM = 60,
$          XFP = 0.0, YFP = 0.0, XG = 0.0, YG = 0.0,
$          ZG = 0.0, PSI = 0.0, NATN = 1, YJITR = 1.0,
$          ZJITR = 1.0, SLEWAZ = 90.0, SLEWEL = 45.0,
$          TRKYIM = 0.0, ATEN = 1.0, RATTEN = 1.E+30,
$          NAIMPT = 1)
DIMENSION FTIM(25), FXCM(25), TIMES(10), ENERGY(10)
DIMENSION FTIM2(25), FXCM2(25), TIMES2(10), GUN(3)
DIMENSION ICOMP(100), PAREA(100), COMPAV(100,10)
DIMENSION COMP(3,100), AP(100,26), WIDTH(100,26), PK(10,100)
CHARACTER*8 NAME(100),BLANK
CHARACTER*4 YORN(2)
```

is used to assign constant values to a number of parameters used in the ASALT input file, to declare array dimensions, and to declare character variables.

The statements

```
DATA YORN /'NO ', 'YES '/
DATA BLANK /' '/
DATA IOUT,IRD,IWR,IIN /4,5,6,11/
DATA AP /2600*-1.0/, PK/1000*0.0/
DATA ENERGY /10*0.0/
DATA COMP /300*0.0/
DATA GUN /3*0.0/
```

are DATA statements which are used to initialize the variables whose names appear in the DATA statement lists. The first three DATA statements set the array YORN which is used to indicate whether the reverse flag is set, assign a string of blank characters to the variable BLANK, and set logical unit numbers used in the FORTRAN I/O operations. The next three DATA statements initialize arrays used to hold presented areas, Pk's, energy flux, and component coordinates. The final DATA statement sets the coordinates of the weapon location in the General Coordinate System.

The statements

```
WRITE (IOUT,103) TDEL,IPRINT,LINLIM
WRITE (IOUT,102) GUN,XFP,YFP,XG,YG,ZG,PSI
```

produce the first two ASALT cards. The first card contains TDEL which is the time interval between iterations of ASALT's computations, and IPRINT and LINLIM which establish the line printer output from ASALT. The second card holds the coordinates for the weapon location and the coordinates for the coordinate system's reference point.

The statements

```

READ (IRD,101) NCRIT
READ (IIN,END=900) AZ,EL,IFMAX,(FTIM(I),FXCM(I),I=1,IFMAX),RVRS,
$ NOCOMP,NTIME,(TIMES(I),I=1,NTIME)
IRVRS = RVRS + 1.
WRITE (IWR,111) (IIN=10),AZ,EL,YORN(IRVRS),NOCOMP,NCRIT,
$ (FTIM(I),FXCM(I),I=1,IFMAX)
WRITE (IWR,112) (TIMES(I),I=1,NTIME)

```

read information on the first vulnerable area file and echo it on the line printer. The first READ statement ascertains the number of critical components in the QKLOOK files. The next READ statement is used to obtain a viewing plane description, the flux distribution with time intervals, the reverse flag, the number of components, and the number and breakdown of time intervals used in the computation of vulnerable areas. The two WRITE statements send this information to the printer file.

The statements

```

WRITE (IOUT,101) IFMAX,NATN
WRITE (IOUT,102) (FXCM(I),I=1,IFMAX)
FTIM(IFMAX) = 1.E+30
WRITE (IOUT,102) (FTIM(I),I=1,IFMAX)
WRITE (IOUT,102) YJITTR,ZJITTR
WRITE (IOUT,102) SLEWAZ,SLEWEL,TRKTIM
WRITE (IOUT,102) ATTEN
WRITE (IOUT,102) RATTEN
WRITE (IOUT,102)
WRITE (IOUT,101) NCRIT,NAIMPT

```

are used to write the laser flux emission rates for ASALT Cards 3 through 11. Card 3 contains the number of elements in the laser flux emission array and the number of elements in the atmospheric attenuation factor array. Cards 4 and 5 contain, respectively, the laser flux emission rates and their corresponding times. Card 6 has the standard deviation due to jitter of the laser beam in the Y and Z direction. Card 7 holds the maximum azimuth and elevation slewing rate for the laser weapon as well as the minimum tracking time required before the laser can fire. Cards 8 and 9 contain, respectively, the laser beam attenuation factor and the beam atmospheric attenuation factor range argument. Card 10 provides the smoke corridor end points. However, no smoke corridor is used in this program, so Card 10 is left blank. Card 11 has the number of components in the target model as well as the number of aim points on the target.

The statements

```

ENERGY(1) = 0.0
IF (NTIME .LT. 10) THEN
  LIM = NTIME
ELSE
  LIM = 9
END IF
DO 20 I = 1,LIM
  T1 = 0.0
  FLUX = 0.0
  J = 0
  15 CONTINUE
  J = J + 1
  IF (FTIM(J) .LT. TIMES(1)) THEN
    DELT = FTIM(J) - T1
    FLUX = FLUX + (FXCM(J) * DELT)
    T1 = FTIM(J)
  END IF
  IF ((J .LT. IFMAX) .AND. (FTIM(J) .LT. TIMES(1))) GO TO 15

```

```

      DELT = TIMES(I) - T1
      FLUX = FLUX + (FXCM(J) * DELT)
      ENERGY(I+1) = FLUX * 0.001
20  CONTINUE
      WRITE (IOUT,102) (ENERGY(I),I=1,LIM+1)

```

are used to calculate the amount of energy accumulated to cause kill probabilities for each component during a specified time interval. These results are used for ASALT Card 12. At time 0, no energy has accumulated, so the first energy argument is set to 0.0. Since ASALT uses exactly 10 energy entries in a function defining Pk at increasing energy levels, and since the first energy level is always set to 0.0, LIM, the number of energy levels to calculate from PEAKAY, is limited to a maximum of 9. The DO loop finds the energy levels for the times specified in the TIMES array. For each cycle through this loop, the first three assignment statements reset the previous time argument T1, the accumulated energy FLUX, and the flux array subscript J to 0. Statement 15 through the conditional GO TO statement form a "REPEAT UNTIL" block and is used to accumulate the energy from the flux distribution table until the flux level for the time of interest is reached. The amount of energy received at this level before the desired time is reached is then added to the previously accumulated energy flux. The energy level is then set to this flux value after it has been converted from joules/cm² to kilojoules/cm². After all the energy arguments have been calculated, they are written to the output file.

The statements

```

      CALL NAMES(NAME,NCRIT)
      DO 250 IIN = 11,36

```

are used to read the names of the critical components and to initiate a DO loop to iterate through vulnerable area files for the standard 26 different aspects.

The statements

```

      IF (IIN .NE. 11) THEN
        READ(IIN,FNO=900) AZ,EL,IFMAX2,(FTIM2(I),FXCM2(I),I=1,IFMAX2),
          RVR,NOCOMP2,NTIME2,(TIMES2(I),I=1,NTIME2)
      RVR = RVR + 1.
      WRITE (IWR,111) (IIN=10),AZ,EL,YORN(RVR),NOCOMP2,NCRIT,
        (FTIM2(I),FXCM2(I),I=1,IFMAX2)
      WRITE (IWR,112) (TIMES2(I),I=1,NTIME2)
      FTIM2(IFMAX2) = 1.E+30
      IF ((IFMAX2 .NE. IFMAX) .OR. (NOCOMP2 .NE. NOCOMP)
        .OR. (NTIME2 .NE. NTIME)) GO TO 950
      DO 300 I = 1,IFMAX
        IF ((FTIM2(I) .NE. FTIM(I)) .OR. (FXCM2(I) .NE. FXCM(I)))
          GO TO 950
      300 CONTINUE
      DO 320 I = 1,NTIME
        IF (TIMES2(I) .NE. TIMES(I)) GO TO 950
      320 CONTINUE
      END IF

```

form an IF block which is executed for every aspect angle except for the first one. This block reads in the azimuth, elevation, flux distribution table, reverse flag, number of components, and times of interest for the next aspect angle. The block then checks the number of components, the flux distribution table, and the times of interest to insure that these values are identical to those for the first aspect angle. If any differ-

ence is found, a GO TO statement branches to Statement 950 to write an error message.

The statements

```

CALL ASPTOIND(AZ,EL,ILOOK)
DO 200 J = 1,NCRIT
  READ (IIN,END=900) ICOMP(J),PAREA(J),(COMPAV(J,K),K=1,NTIME)
  IF (NAME(J).EQ. BLANK)
    $ WRITE (NAME(J),195) ICOMP(J)
    $ WRITE (IWR,113) J,NAME(J),ICOMP(J),PAREA(J),(COMPAV(J,K),
    $ K = 1,NTIME)
200 CONTINUE

```

are used to convert the look angles to an ASALT index and to read the presented and vulnerable areas for each critical component. The CALL statement obtains the ASALT index associated with each of the 26 views. The DO loop reads the presented and vulnerable areas for each critical component, assigns the component's number to the name array when the component's name is not already in the array, and writes this information out. The component name information is used in preparing Card 13 for the ASALT program.

The statements

```

DO 240 J = 1,NCRIT
  AP(J,ILOOK) = PAREA(J) * 0.09290304
  WIDTH(J,ILOOK) = SQRT(AP(J,ILOOK))
  PK(I,J) = 0.0
  IF (PAREA(J).GT. 1.E-06) THEN
    DO 230 I = 2,LIM
      PK(I,J) = PK(I,J) + COMPAV(J,I-1) / PAREA(J)
230 CONTINUE
    END IF
240 CONTINUE
250 CONTINUE

```

are used to prepare ASALT Cards 14 and 15. The outer DO loop iterates for every critical component for each look angle. The first assignment statement converts the presented area from square feet to square meters. The next assignment statement assumes that the presented area is square and calculates the width in meters. The third assignment statement states that the probability of kill at time zero when no energy has accumulated is zero. The IF statement checks whether the presented area for the current component is zero. If not, the DO loop in the IF block sums the Pk's for each component for all views. Statement 250 closes the loop that iterates through the 26 aspect angles.

The statements

```

400 DO 410 J = 2,LIM
  DO 405 I = 1,NCRIT
    PK(J,I) = PK(J,I) / 26.0
405 CONTINUE
410 CONTINUE

```

form two nested DO loops which average the Pk's for each component from all 26 views for each time of interest.

The statements

```

CALL GETXYZ(ICOMP,COMP,NCRIT,NAME)
WRITE (IAR,121)

```

```

DO 450 I = 1, NCRIT
  WRITE (IOUT,104) NAME(I), (COMP(J,I), J=1,3)
  WRITE (IOUT,102) (AP(I,J), WIDTH(I,J), J=1,26)
  WRITE (IOUT,102) (PK(J,I), J=1,10)
  WRITE (IWR,122) I, NAME(I), ICOMP(I), (J, AP(I,J), WIDTH(I,J), J=1,26)
450 CONTINUE

```

produce ASALT Cards 13, 14, and 15 for each critical component. The CALL statement determines the location in the Aircraft Coordinate System. The first WRITE statement sends a form feed to the print file. The DO loop iterates for each critical component. The next WRITE statement forms Card 13 by listing the name and coordinates for the component. The third WRITE statement outputs the presented area and width of the presented area for Card 14. The fourth WRITE statement outputs the average Pk at each specified time for the component for Card 15. The final WRITE statement is used to print the information from Cards 13 and 14.

The following statements

```

  WRITE (IWR,123) (ENERGY(I), I=1,10)
DO 500 I = 1, NCRIT
  WRITE (IWR,124) I, NAME(I), ICOMP(I), (PK(J,I), J=1,10)
500 CONTINUE
  WRITE (IOUT,125)
  STOP

```

print the energy flux distribution and the information from Card 15. Additionally, a reminder to the user to finish assembling the ASALT input deck is output.

The statements

```

900 WRITE (IWR,126) IIN,J
  STOP

```

are used to terminate the program when the end of file is reached unexpectedly when reading data on a particular aspect. The WRITE statement prints an error message.

The next statements

```

950 WRITE (IWR,127) IIN
  STOP

```

are used to terminate the program if a difference in values is detected between different views where no difference is expected. The WRITE statement prints an error message.

The last group of statements

```
