19. KEY WORDS (Continue on reverse side if necessary and identify by block number) Snow Snow cover Snow properties		
20. ABSTRACT (Continue on reverse side if necessary and identify by block number) A complete meteorological field station and a snow survey network were set up in the Allagash River Watershed to record baseline conditions prior to construction of the proposed Dickey-Lincoln Dam in the upper St. John River Basin in Allagash, Maine. Nearly three years of daily data (Oct 1977-May 1980) are summarized and compared to long-term climatic conditions for nearby National Weather Service stations. Air temperature values for Allagash are similar to those for the two nearest meteorological stations; water equivalent precipitation amounts and snowfall totals in the Allagash basin are inconsistent with those for nearby meteorological stations.		

PREFACE

This report was prepared by Roy E. Bates, Meteorologist, Geophysical Sciences Branch, Research Division, U.S. Army Cold Regions Research and Engineering Laboratory. The study was funded by the Office of the Chief of Engineers, Water Resources Support Center under the Civil Works Remote Sensing Research Program, CWIS 31584, Snow Cover Analysis Using Landsat Digital Data.

The U.S. Army Atmospheric Sciences Laboratory (White Sands, New Mexico) meteorological teams based at CRREL, Hanover, New Hampshire, and Maynard, Massachusetts, furnished and assisted in installing the meteorological instrumentation and tabulated the meteorological field data for the Allagash site.

The author thanks Roy Gardner, Physical Sciences Technician, New England Division, U.S. Army Corps of Engineers, Waltham, Massachusetts, who was on site during the three years of the study. His dedication in maintaining and operating meteorological equipment and collecting valuable snow property and snow survey measurements made this report possible. The author also thanks Carolyn J. Merry and Richard K. Haugen of CRREL for their constructive reviews of the report.

SNOW COVER AND METEOROLOGY AT
ALLAGASH, MAINE, 1977-1980

by

Roy Bates

INTRODUCTION

In October 1977 CRREL began collecting data for a project to analyze snow cover in New England using Landsat digital data. The objective of this portion of the study was to examine the physical properties of the snow cover in the proposed watershed for the Dickey-Lincoln Dam in the upper St. John River basin in Allagash, Maine. Eleven snow survey sites (where water equivalent snowfall and snow depth were measured) were selected from 17 initial sites surveyed in the Allagash River watershed (Fig. 1). Table 1 gives the locations and characteristics of the 11 sites. Snow property or pit studies were made at three of these sites according to the methods described in CRREL (1962). Data were collected at all sites for the winters of 1977-78, 1978-79 and 1979-80.

Meteorological instrumentation was installed at site 1 to provide baseline meteorological data for nearly three years prior to construction of the proposed dam. On-site meteorological data were required since it was unknown whether data from Caribou, Maine, the nearest meteorological station with summarized data (80 km east of the Allagash site), would be representative of the area under consideration. The meteorological data collected during this experiment are compared with data from both the Caribou National Weather Service Station and the nearby Fort Kent, Maine, Cooperative Station to see if any similarities existed. These background meteorological and snow-cover data would then serve as a basis for predicting mesoscale climatic changes resulting from the construction of the proposed Dickey-Lincoln hydroelectric project.

This report also describes the measurement equipment and its installation, and summarizes the data. Also, snow-survey sampling techniques and snow property measurements are discussed. The ground-truth data on snow depths and water equivalents in this report were collected for comparison to Landsat digital data for the same dates.

Figure 1. Locations of study sites.

METEOROLOGICAL MEASUREMENTS

In October 1977 CRREL installed a meteorological instrument shelter at site 1 (Fig. 1). The shelter contained maximum and minimum thermometers and a hygrothermograph for recording air temperature and relative humidity. A weighing-type rain gauge was also installed for measuring water equivalent precipitation. Other daily measurements included sky cover, snowfall, snow depth, and duration and type of precipitation. Beginning in October 1978 incident solar radiation and wind speed and direction were also measured except during a six-month period (May-October 1979) when wind data were not obtained due to equipment failure. Data were compiled and tabulated for each day in the 32 months between October 1977 and May 1980

(Appendix A). The results obtained for some of the meteorological parameters are described in the following sections. Due to intermittent problems with some of the instruments, some monthly averages and/or totals are incomplete, preventing exact comparisons with nearby weather stations.

Air temperature

Mean monthly air temperatures computed from daily values (averages of daily maximum and minimum) are compared for the period of record in Table 2 and Figure 2. In Figure 2 these values are compared with the long-term mean monthly air temperature for Caribou, Maine (the nearest first-order climate station with long-term monthly summaries of air temperature values). Mean annual temperatures were computed for the Allagash site for 1978 and 1979 using the monthly means (Table 2), even though the data were incomplete due to equipment failure. Figure 3 compares the mean monthly temperatures in winter at Allagash to those obtained at Caribou and Fort Kent (U.S. Department of Commerce 1977-1980a,b). For both the annual and the winter monthly averages, Fort Kent's air temperatures more accurately represent the Allagash area. Allagash's mean annual temperature for 1978 and 1979 were 1.5° and 3.8°C, respectively; Caribou recorded annual means of 3.6° and 5.4°C, whereas Fort Kent's annual means were 2.3° and 3.9°C for the same period.

Precipitation

The rate, amount, duration and type of precipitation for the upper St. John River are important considerations in the construction of a dam and the subsequent ponding of a large volume of water. Therefore, daily rainfall and water equivalent amounts of frozen precipitation, as well as the duration of precipitation recorded on the rain gauge at site 1, are presented in Appendix A. The type of precipitation was noted by the observer at the site. The winter monthly totals for October 1977-May 1980 are summarized on Figure 4. (Some of these monthly totals are also incomplete due to instrument failure.) Precipitation data from Fort Kent and Caribou (U.S. Department of Commerce 1977-1980a,b) were compared to the data obtained at the Allagash site since monthly and 30-year averages are available for both sites (Table 3). It was hoped that the data for either Fort Kent or Caribou could be substituted for long-term averages of precipitation on the Allagash watershed. Although the long-term monthly averages for Fort Kent and Caribou are essentially equal, monthly variations between October 1977 and May 1980 were as high as 90 mm (July) between the two sites. Similarly neither of the monthly averages from these two sites consistently correlated with the data from the Allagash site. Therefore, unlike temperature, total precipitation amounts at the sites do not show similar trends.

Figure 5. Snow depths for three winters at Allagash.

Snow depths on the ground are plotted in Figure 5 for the three winters. These data show that the first two winters (1977-78 and 1978-79) received approximately the same amount of snow. Despite the similarities in snow depth, the maximum snow depth on the ground in the winter of 1977-78 was 118 cm, while the maximum for the following winter was almost 30 cm less (89 cm). In both winters, snow began to accumulate in mid-November. A severe thaw accompanied by rain in late March 1979 (the maximum daily temperature reached a high of +18.6°C on 23 March; see Appendix A) rapidly depleted the snowcover, causing the discrepancy between the maximum snow depths recorded during the first two winters of measurements.

In contrast to the two previous winters, the third winter (1979-80) at Allagash, Caribou and Fort Kent had approximately half the total snowfall. Precipitation amounts (water equivalent) were considerably below the previous two years, especially during January and February (Fig. 4). The monthly winter water equivalent precipitation differed the most from the long-term normal in March 1978, when the water equivalent was greater than twice as much. Since the monthly average air temperatures were similar during the three winters, the lack of snow accumulation in 1979-80 was due primarily to a lack of storm systems reaching the area; this was the trend throughout northern New England (U.S. Department of Commerce 1977-80a). Figure 5 shows that once the snow began to accumulate in early December 1979, it stayed on the ground until the spring thaw, with only one notable midwinter thaw (12 January 1980). Although Allagash recorded more snow

Figure 6. Snowfall comparisons for Allagash, Fort Kent and Caribou. (T = trace).

(both in terms of depth and water equivalent) than most climatic stations in northern New England in the winter of 1979-80 (U.S. Department of Commerce 1977-1980a), snow began to accumulate later, less precipitation fell, and the snow cover melted earlier than in the previous two winters. The total yearly snowfalls at Allagash, Caribou and Fort Kent (Fig. 6) are similar, but the monthly amounts of the two National Weather Service sites are too variable for the sites to be used as substitutes for the Allagash basin.

Wind

Daily average wind speed and prevailing direction at the Allagash site during the study are tabulated in Appendix A. Wind data collection began in late October 1978 and continued until May 1980, except for a six-month interruption due to equipment failure (May-October 1979).

Average monthly wind speeds between 1.1 and 1.7 m/s were recorded during the two years of wind measurements at site 1. These average recorded speeds are not representative of the watershed in winter, because the measurement site was in a valley and sheltered from high winds by conifer trees.

The daily predominant wind direction provides an estimate of the prevailing direction for each month. The direction of the winds during the winter and early spring was variable. The winds tended to blow from a westerly direction (SW through NW) during the winter, shifting to the southeast as spring approached.

However, as with other meteorological parameters, the length and/or incompleteness of records at the Allagash site and the lack of a comparative wind recording station prevented any definite conclusions.

SNOW SAMPLING AND SNOW PROPERTY MEASUREMENTS

A second focus of the study was the snow sampling survey and snow property measurements performed in and around Allagash. Seventeen sites were originally chosen for snow sampling measurements; of these, 11 of the more accessible sites were selected for sampling (Table 1). Their elevations range from 186 m above sea level near the river in (site 1) to 442 m above sea level (site 15). Snow depth and water equivalent were measured

at least once per month during December, January and February, twice per month during March, and once per week during April until the sites were snow-free. The only exception was site 1, where data were measured on a weekly basis. Snow property data were measured in accordance with CRREL (1962).

So that a future study could test whether Landsat digital data correlated with ground-truth data on snow properties where elevations, slope, aspect and vegetative cover are known, snow measurements were made within a day of the scheduled Landsat overpasses. The ground-truth snow data for the three winters are presented in Figure 7. Appendix B provides a detailed, site-by-site breakdown of snow depth, water equivalent and snow density (density = water equivalent/depth) for each winter.

Appendix B also summarizes the snow densities measured at three snow pit sites (sites 1, 9 and 15). At each of these sites, snow pit density measurements were performed at the same time as the snow sampling survey. Averages of snow density from the three pit sites and from the 11 snow survey sites are plotted in Figure 8. Snow surface characteristics, total snow depth, snow density, temperature, hardness and crystal classification were monitored at each snow pit. The original data are available from CRREL.

SUMMARY

This report examines meteorological data for nearly three years and snow property conditions for three winters in Allagash, Maine. Meteorological variables are compared to nearby climatic stations at Fort Kent and Caribou, Maine. The monthly mean temperature data from Allagash correlated closely with the monthly values from Fort Kent Cooperative National Weather Service Station. The mean annual temperature differences between Allagash and Fort Kent were 0.8° and 0.1°C for 1978 and 1979, respectively; the differences between Allagash and Caribou were 2.1° and 1.6°C.

Few similarities were found between the precipitation data from Allagash and the data from Caribou or Fort Kent. Even though total precipitation for some months was similar, the annual values varied widely. Also, both Fort Kent's and Caribou's annual precipitation totals throughout the test period differed significantly from the long-term normal. A similar lack of correlation also existed in the monthly snowfall amounts.

Even though annual snowfall amounts were similar between sites, the winter of 1978-79 total snowfall amounts at Fort Kent and Caribou differed from the Allagash amounts by 15 and 22%, respectively.

In summary, air temperature values for Allagash are similar to the two nearest meteorological stations: Fort Kent and Caribou; however, water equivalent precipitation amounts and snowfall totals in the Allagash basin are inconsistent with nearby meteorological stations. The meteorological and snow property data presented in this report for the Allagash site, together with concurrent LANDSAT digital data being presented by Merry and Miller (in prep.), will serve as excellent baseline data for climatic assessment if the proposed Dickey-Lincoln hydroelectric project proceeds in the future.
