20. ABSTRACT (Continue on reverse side if necessary and identify by block number) Standardized acceptance test procedures have been developed to enable the Navy to check precisely the performance characteristics of its new synthesized microwave signal generators which operate over a frequency range of 0.1 to 26.5 GHz (gigahertz). Extensive use of IEEE-488 bus-controlled instrumentation and a central processor/computer allows most of the measurements to be done automatically. Details of the individual tests performed and the hardware and software used to implement the tests are given. Test time has been reduced by at least a factor of five (conservative estimate), and test accuracy and repeatability have been enhanced significantly.		

Automated Acceptance Test Procedures for Wideband Microwave Synthesized Signal Generator Testing

AUTOMATED ACCEPTANCE TEST PROCEDURES FOR WIDEBAND MICROWAVE SYNTHESIZED SIGNAL GENERATOR TESTING

INTRODUCTION

The Naval Research Laboratory (NRL) has been tasked by the Naval Electronic Systems Command (NAVELEX) to develop automated acceptance test procedures to be used to evaluate the performance characteristics of the Navy's new wideband microwave synthesized signal generators. The test system developed makes maximum use of IEEE-488 bus controlled instrumentation and a central processor/controller which allows most measurements to be accomplished under processor control. Use of the Hewlett-Packard Model 8566A Spectrum Analyzer and other new equipment under bus control has virtually eliminated the need for subjective judgments by the test operator. The time required for completion of the tests has been greatly reduced. Test results are more accurately and precisely documented. Test procedures are standardized and precisely defined.

Details of the individual tests performed and the hardware and software used to implement the tests are included in the appendices. These procedures represent refinements and improvements developed after intensive use for 6 to 9 months.

Two sample units from each Systron-Donner Corporation or Giga-tronics, Inc., production lot of 10 are selected at random in accordance with the testing requirements [1,2]. They are shipped to the Navy testing facility where they undergo rigorous production tests to verify that the equipment meets applicable specifications. If both samples pass all tests, the entire lot of 10 is accepted by the Navy and delivered to the Fleet. Should either sample fail to meet the specifications, the entire lot may be rejected. When the problem is remedied, another random sample of two units is selected and the testing restarted. The cost of all retested lot samples is charged to the manufacturer.

PERFORMANCE ACCEPTANCE TESTS

A listing of the acceptance tests for the production-lot sample follows.

- Status: Frequency lock and amplitude level; performed at normal, minimum, and maximum operating temperatures.
- Level accuracy: Power output level (dBm) vs frequency (GHz); normal, minimum, and maximum operating temperatures.
- Maximum output: Maximum unlevelled power (dBm) vs frequency (GHz); normal minimum, and maximum operating temperatures.
- Level calibration: Verification of attenuators to -90 dBm.

- Spur hunt: Search (0.01 to 23 GHz) for harmonic and non-harmonic outputs caused by 20 randomly selected output frequencies.

- Phase noise: At 10 kHz, offset for 20 randomly selected frequencies.
- On/off ratio: Pulse/square wave carrier ON:OFF ratio; 10 frequencies.
- Sweep output: Output level and ramp output check in sweep mode.
- Center frequency pulling: Due to pulse modulation.
- Power meter accuracy: Internal PM vs external reference PM.
- Internal pulse width: Internal calibration, maximum, minimum pulse widths.
- External pulse modulation: Verify operation; external pulse generator.
- External reference lock: Verify operation with external reference.
- Remote control: Check operation with IEEE-488 bus controller.
- Residual FM: Residual FM on unmodulated CW output.
- Frequency counter: Verify frequency counter function operation.
- Cable calibration: Verify cable calibration function operation.

The last two items apply only to the Giga-tronics Model 1026. These features were added by the manufacturer and not required by the specification; however, since they are available, both must be functioning properly for the sample lot to pass.

The details of these sample production-lot tests are the subject of the remainder of this report.

TEST EQUIPMENT REQUIRED

The test equipment required is listed below. If the suggested model can be replaced by an equivalent instrument, /eq will follow the model number. However, if the suggested model is *not* used, the software listed in the appendices may have to be modified to accommodate the equipment used.

Equipment	Suggested Model	IEEE-488
Spectrum analyzer	HP-8566A	Y
Power meter	HP-436A /eq	Y
Power sensor (+10 to -30 dBm) Coaxial 10 MHz to 26.5 GHz	HP-8485A /eq	N
Computer/controller	HP-26/36 /eq	Y
Crystal detector (Coax .01 - 26.5 GHz)	HP-8473C /eq	N
A/D converter or DVM	HP-59313A /eq	Y

Equipment	Suggested Model	IEEE-488
Pulse/function generator	HP-8111A /eq	N
Crystal reference (5 MHz)	HP-5062C /eq	N
Microwave frequency counter, coaxial input DC to 26.5 GHz	SD-6054B /eq	Y
Modulation analyzer	HP-8901A /eq	Y
Microwave synthesizer	HP-8340A /eq	Y
Mixer (coax/10 GHz)	MITEQ MCO-1A /eq	N

DESCRIPTION OF PRODUCTION TESTS

Status: Frequency Lock and Amplitude Level

In this test, the frequency of the unit under test (UUT) is varied in 10 MHz steps over the entire operating frequency range (FR) of 100 MHz to 26.5 GHz, while the output amplitude is maintained at its maximum leveled value of +5 dBm. At each of the 2640 frequency steps, the UUT is commanded by the test controller to send back its status message for interrogation. Contained in this binary message is an indication that the UUT's output frequency is phase locked to its reference frequency and that the output amplitude leveling loop is within its operating range and able to maintain the proper output power level to within ± 1 dB. A false indication for either or both of these status messages triggers the controller to print the fault condition and the frequency at which it occurred on a hardcopy test record.

This test is performed at room temperature on both test samples after they have been unpacked and turned on for at least 1 hour. It is also performed every 4 hours during both the maximum and minimum operational temperature tests.

Appendix A shows a typical printout from this test, the block diagram of the test set-up, and a listing of the program on the HP-85 controller, written in Basic. At the start of the test run, the first line printed is the test frequency range as: RANGE | 0.1 $\rightarrow$ 26.5 | Steps 2640. This means that 2640 frequency steps are taken from 0.1 to 26.5 GHz. Any frequencies at which there is an UNLOCK or UNLEVEL status message are printed next. The end of the test run is signaled by "STATUS TEST" followed by the model and serial numbers of the UUT, the date and time of test completion, and the temperature and relative humidity.

Output Level Accuracy: Power Out (dBm) vs Frequency (GHz)

This test monitors the UUT's output power level with a Hewlett-Packard (HP) 436A power meter and 8485A sensor, which is capable of making coaxial power measurements from 10 MHz to 26.5 GHz. The UUT's frequency is stepped by any desired increment greater than 1 MHz (usually 100 MHz is chosen) over the full FR, and the power meter sends the output power level to the controller. The controller adds to this raw power reading any correction factors necessary to compensate for the calibrated roll-off (vs frequency) of the particular power sensor used. If any coaxial cables are used between the UUT's output and power sensor's input, their correction factors are also added at this time. The final corrected output power level vs. frequency is then plotted and becomes a permanent record of the UUT's output power accuracy.

This test is usually performed at power levels of +5 dBm and -4 dBm, giving two plots on the same set of axes. Like the status test, this test is performed at room temperature after initial warm-up and immediately following both the maximum and minimum operating temperature runs. If any discrepancies are detected, the parameters of the test may be easily varied to make a detailed study of the problem area.

Appendix B/C shows a typical plot generated by this test, the test set-up block diagram, and a listing of the program on the HP-26/36 controller(s) written in HPL language. The data plot gives the model and serial numbers of the UUT, the ambient temperature during the test, and the date and time that the test was completed. The straight horizontal lines on either side of the plotted data are ± 1 dB about the set level of the UUT. Vertical lines are drawn at 18 GHz and 26 GHz to mark the region where the level accuracy specification changes to ± 2 dB.

Maximum Output: Maximum Unleveled Power (dBm) vs Frequency (GHz)

The program and test configuration for this test are similar to those used in the output level test. The only difference is that the output level called for by the controller is greater than the unit is capable of producing. This causes the UUT to output the maximum power it has available in an unleveled mode. The plot in Appendix B/C shows this unleveled fluctuation very clearly on a set of axes similar to those used for the level accuracy plot. The important criterion for this plot is that the lowest value of the unleveled output power must be greater than +5 dBm for the leveling loop to operate correctly at +5 dBm.

Level Calibration: Verification of Output Attenuator

This test involves checking the 10 dB/step attenuator of the UUT over its entire operating range of 0 to -90 dB. Since the number of possible measurements which could be made is extremely large, five frequencies (0.1, 2, 9, 18, and 22 GHz) across the FR of the UUT were selected. If a problem is detected or suspected, more frequencies in the suspect region may be examined. If any errors in attenuator calibration are found, they are confirmed by making a completely independent measurement with the Weinschel VM-4A.

The programmable spectrum analyzer was chosen for this test over the Weinschel VM-4A for several reasons: simpler test configuration, less time required to make connections, frequency range is covered by single test set-up (VM-4A limited to 18 GHz without external down conversion), and the analyzer allows an operator to view actual level of signal being measured (confidence in measurement is increased). A discussion of the WM-4A program and operation is the subject of a soon-to-be released report [3].

Since the attenuator on the SD-1626 is not programmable, while that on the GT-1026 is programmable, two separate versions of this program had to be written. Only the Giga-tronics version is given in Appendix D. The Systron-Donner version differs in that each time the attenuator is stepped the program must pause, tell the operator to make the step change, and then continue with the measurement. The output data from this test can be configured in two ways: all measurements can be printed in tabular form, or only errors greater than a specified limit can be printed; this saves paper and operator time in examining the data. Appendix D shows this latter type of data presentation. The program is arbitrarily set to print out whenever an error greater than ± 1.5 dB is detected between the Nom Level and Meas Level columns. The test printout includes the date, model and serial numbers of the UUT, and the magnitude to any detected errors shown in the Diff (difference) column. The completion of the test is signaled by a two-line printout. The first line gives the condition for error printing, and the second line lists the frequencies which were checked. The program listing given in Appendix D is, again, for the HP-26/36 controller(s) using HPL language and mandates the use of a HP-8566A Spectrum Analyzer.

Spur Hunt: Harmonic/Nonharmonic Spurious Response Search

This test programs the UUT to output approximately 20 randomly selected, unmodulated frequencies. At each frequency, the 8566A Spectrum Analyzer examines successive 1 GHz-wide portions of the frequency spectrum for any discrete responses greater than the specification limit of -55 dBc. If any responses are found, the analyzer determines their frequency and level and prints them out on the hardcopy test record. After the test is complete, any printouts which exceed the specification are examined in a manual mode of operation to verify that they are true responses at the levels indicated. This test consumes approximately 20 minutes of actual running time and is a good example of the power of the automated testing procedure.

The printout for this test in Appendix E shows a line which indicates that the UUT was set to a specific test frequency (1026 Set Freq = X.XXX GHz), followed by all the detected responses (frequency and level) for that set frequency on indented lines. If no spurious responses were detected, only the fundamental output responses (indicated by its high level) should be printed. At generator frequencies above 23 GHz, the fundamental is not detected because the search is only from 0 to 23 GHz. To obtain the true level of any spurious response relative to the fundamental (dBc), a correction for the cable loss at the spurious frequency must be added to the values given in the Level (dBm) column of the data sheet. This program, written for the HP-26/36 controller(s), uses HPL language and necessitates the use of the HP-8566A Spectrum Analyzer.

Phase Noise: 10 kHz Offset in 1 Hz Bandwidth

This test programs the UUT to output approximately 20 randomly selected, unmodulated frequencies. At each frequency, the 8566A Spectrum Analyzer tunes itself to center the selected frequency, opens its span to 10 kHz/div, and measures the noise level one division away from the carrier frequency. The firmware in the 8566A then converts the measurement from the measurement bandwidth to an equivalent 1 Hz bandwidth. The data printout from this test gives the frequency of the test, the measured carrier level (dBm), the 10 kHz offset level converted to a 1 Hz bandwidth in dBm/Hz, and the phase noise at the 10 kHz offset in dBc/Hz.

This program is written for the HP-26/36 controller, using HPL language, and requires the use of the HP-8566A spectrum analyzer. This test requires approximately 3 minutes to complete. The test setup is identical to that used in the spur hunt test and is given again in Appendix F for consistency.

On/Off Ratio: Pulse or Square Wave Carrier On to Off Ratio

This test programs the UUT to output approximately 20 randomly selected frequencies, to which internal square wave modulation is applied. The 8566A is tuned to each frequency, and its span is set to zero Hz to recover the modulated square wave. The delta marker function of the analyzer is then used to measure the peak-to-peak value of this recovered modulation in dB, which just happens to be the desired on/off ratio. Each reading and its frequency is recorded on the hardcopy printout. After the final ratio is measured, the average on/off ratio for all the measurements is computed and printed.

Typical data from this test, the measurement test set-up, and a listing of the test program written for the HP-26/36 controller(s) in HPL language is shown in Appendix G. The program listing is the Systron-Donner version. Separate versions are necessary due to the software operation of the square-wave modulation function.

Sweep Output: Sweep Mode Level Output Check; Ramp Output Check

This test calls for the swept output of the UUT to be measured via a crystal detector connected directly to the RF output. The output of this detector is sampled by an A/D converter which takes readings every 10 ms. At the completion of the sweep, the A/D detector is set to monitor the sweep ramp output voltage as the frequency again is swept through the same range as before. The detector output is plotted on the Y-axis vs the ramp voltage on the X-axis. The output of the detector is then calibrated in dBm by reconnecting the A/D cable to the crystal detector and by plotting the measured response for various dB settings of the UUT's output as its CW frequency is stepped (20 steps) across the range of the sweep.

Some typical plots from this test, the test set-up, and a program listing for the HP 26/36 controller(s) in HPL language are given in Appendix H. On the plot, the left vertical axis is proportional to the output voltage of the crystal detector. The right vertical markings give the translation of these relative A/D numbers to power levels in dBm. The horizontal frequency axis is a constructed digital scale based on the analog sweep ramp voltage and the sweep start and stop limits. The discrete spikes which occur are due to band changes, another oscillator being switched in to provide the output over that portion of the sweep range.

Center Frequency Pulling: During Pulse Modulation

This test measures the amount that the center frequency of the UUT is displaced due to the incidental FM created during pulse modulation of the UUT's CW output frequency. The modulation applied to the CW signal is 10 microseconds (μ s) wide at a pulse repetition frequency (PRF) of 5 kHz. The program, written in HPL for the HP-26/36 controller, requires the use of the HP-8566A Spectrum Analyzer. The UUT's output frequency may be varied over all or any portion of the 0 to 23 GHz range of the analyzer. For this test the pulse-modulated CW frequency is stepped in 100 MHz steps from 100 MHz to 23 GHz. At each frequency step, the analyzer tunes to the set frequency and recovers the modulation envelope pattern of the pulse modulated signal. Using the delta frequency marker function of the 8566A, the frequency shift (+ or -) is measured between the set frequency at the center of the display and the peak of the detected envelope. From this difference, the frequency offset of the center frequency of the modulated signal from the true center frequency of the CW output is computed. If this offset is greater than 1 part in 10^{-6} (1pp10⁶), the printer outputs the set frequency; the frequency error, Δf , in Hz; and the frequency offset, $\Delta f/F$, in parts. At the conclusion of the test, the maximum positive and negative offsets are printed with the number of frequencies which exceeded 1pp10⁶.

A typical data sheet giving the date of the test, the model and serial numbers, the program listing in HPL language, and the test setup is shown in Appendix I.

Power Meter Accuracy: Internal PM vs External Reference PM

In this test, power measurements are made with the internal crystal power meter (PM) of the UUT for comparison to identical measurements made with a calibrated HP-436A PM. The differences at each frequency and level are then computed for comparison with the specification. Provision is made within the program for two separate 8485A sensors and their appropriate correction factors which will be used to make the reference measurement.

Appendix J gives the diagram for the test setup, a program listing in HPL for the HP-26/36 controller(s), and a sample data printout from a typical test. The program is flexible; it allows any start, stop, and step size to be chosen for this test. The Giga-tronics 1026 test generally is run from 2 GHz to 26 GHz, in 2 GHz steps, at three or four power output levels from 0 to -25 dBm, since

the power reading from the UUT can be made automatically via the IEEE-488 bus. The step size for this test is usually selected to be 4 GHz since the PM readings from the Systron-Donner 1626 must be typed in manually as they are read from the UUT's front panel. For this reason and because of the cable/sensor switching involved, two separate versions of this test have been written, neither of which is totally automatic from start to finish. The data sheet first lists the output level setting of the UUT for the test. This is followed by six columns of data: the frequency in GHz, the UUT PM reading in dB, the reference PM readings from the HP-436A, and the difference of the UUT reading minus the reference readings. For output levels greater than -20 dBm, the differences should be less than ± 1 dB below 18 GHz and ± 2 dB above 18 GHz. For outputs from -20 dBm to -30 dBm, the specification is ± 2 dB and ± 3 dB respectively.

Internal Pulse Width: Calibration, Maximum, Minimum Pulse Widths Measured

In this test, the internal pulse modulator operation is checked by setting its pulse width to the calibrated 1 μ s position, the variable minimum pulse width position, and the variable maximum pulse width position at a PRF of 5 kHz and about ten different RF output frequencies across the FR of the UUT. For each pulse width at each frequency, the 8566A is tuned to place the RF output frequency at the center of the display. The span appropriate to the pulse width is then chosen, so that the first two or three lobes of the modulated $(\sin x)/x$ pattern are displayed on the analyzer's CRT. The test operator is told to move the marker to the first null above the main lobe. With this marker positioned correctly, the operator continues the program, which reads the marker separation in kHz and computes the pulse width in μ s as the reciprocal of this separation. This procedure is followed for each of the three pulse widths at every frequency. After the maximum width is measured, the controller displays the results of these calculations in the table format shown in Appendix K.

Since neither the variable pulse width nor PRF controls are programmable, this test is only semiautomatic. This means that the program operation must be halted while the test operator performs a nonprogrammable function and then restarted after the action is completed. Two separate versions of this program are required due to the differing nature of the bus controls on the units from two separate manufacturers. The test configuration and Systron-Donner version of this program, which is written in HPL for the HP-26/36 controller(s) and requires approximately 10 minutes to complete, are given in the sample data printout in Appendix K.

External Pulse Modulation: Visual Verification

This semiautomatic test uses three pulse widths and four PRFs from an external pulse generator to modulate five different RF frequencies from the UUT through its external modulation input jack. Initially, the modulation is applied to a 3 GHz carrier, and the 8566A is adjusted to display the familiar $(\sin x)/x$ pattern. Then the RF frequency is changed while the test operator observes the spectrum analyzer display and verifies that the same general pattern is present at the other RF frequencies. Each time a change in the modulating signal is required, the operator is instructed by the controller, and the new condition is manually set on the pulse generator. This allows any available pulse generator to perform this test. The printout for this test is simply the test name and date along with the model and serial numbers of the UUT. Any notes on anomalies in the observed patterns can be typed in by the test operator following these data.

Two separate versions of this test were required also due to the differing nature of the bus controls. The test verification printout, the test setup, and a listing of the program for the Gigatronics generator written in HPL for the HP-26/36 controller(s) are given in Appendix L.

External Reference Lock: Operation from an External Standard

This test checks the UUT's ability to synchronize its output frequency with an externally applied reference signal. Since the UUTs from the two different manufacturers require different reference frequency inputs (10 MHz for the Gigatronics, 1 MHz for the Systron-Donner), the test configuration shown in Appendix M can generate either of these references from a standard 5 MHz crystal source. Due to this difference, this test is also written in two separate versions. The program initially displays the test setup on the controller's CRT and waits for the test operator to make the necessary connections. After the correct reference is generated by the HP-8111A function generator, it is plugged into the UUT's reference input. The UUT is then programmed for approximately 20 CW output frequencies across its entire frequency range. At each frequency, the output frequency is checked on the counter, which is driven by the same reference. The status message from the UUT is read by the controller to ensure that the generator is locked to the external reference and levelled. If the frequency error is greater than 1 kHz, the printout will state this in kHz, together with the magnitude of the error.

The program listing given in Appendix M is for the Systron-Donner unit and is written in HPL for the HP-26/36 controller(s). The frequency counter used in this test, for which the software in the program listing is written, is the Systron-Donner Model 6054B.

Remote Control Operation: IEEE-488 Bus Operation

There is no specific test which checks the remote operation via the IEEE-488 bus. This function is checked by the proper operation of the UUT during all the other tests listed in this report.

Residual FM: Residual Frequency Modulation on CW Carrier

This test uses the HP-8901A Modulation Analyzer to measure the residual FM present on the UUTs CW carrier in a 50 Hz to 15 kHz bandwidth. For residual FM, the AVERAGE detector measurement is made, and this result is multiplied by $\sqrt{2}$ and $2\sqrt{2}$ to obtain the peak and peak-to-peak readings shown in the data. The residual FM specification is less than 1 kHz peak-to-peak (p-p) in a 50 Hz to 15 kHz bandwidth at output frequencies below 1 GHz. Above 1 GHz, the specification is 0.0001% of the CW carrier frequency. Due to the input frequency limitation of the 8901A, which is 1.3 GHz, two separate versions/configurations of this test are used. These are both given in Appendix N. For frequencies above 1.2 GHz, the second test setup is used. This employs a mixer and another synthesizer as a local oscillator to translate the output of the UUT down to the measurement range of the 8901A. In most cases, the beat frequency chosen in this set-up was 1.0 GHz. The residual FM of the local oscillator must be substantially below that of the UUT to be measured; an HP-8672A or HP-8340A work well in this application. If no high quality local oscillator is available, two of the UUTs may be used with the assumption of equal contribution to the measured residual FM. In this case, the final results should be divided by the $\sqrt{2}$ to obtain the residual FM for a single unit. For this special case, the peak-to-peak residual FM of a single UUT is equal to twice the measured AVERAGE FM reading of the 8901A.

The program for residual FM, written for the HP-26/36 controller(s) in HPL language, is given in Appendix N along with a typical printout of the test data.

Frequency Counter Operation: Checks Counter (Giga-tronics only)

This test is not covered by the equipment specification since the frequency counter function is an added feature of the Giga-tronics 1026. However, since it is available and will be used when the units are deployed in the Fleet, verification of its proper operation is necessary. The simplest manner in which this check may be made is to use two Giga-tronics units, one as the UUT and the other as the frequency source to be counted. The Program written in Appendix P was developed for this. This requirement is necessary because a single Giga-tronics unit cannot count directly its own frequency. The program sets the frequency source to approximately 10 random CW frequencies. It then sets up a search window on the counter UUT which encompasses the particular source frequency. The UUT counter is then put into its measure mode. When it locks onto the input frequency, the front panel of the UUT displays the measured frequency. It is then available to be read by the controller, which prints the set frequency, measured frequency, and the difference on the test record. If the counter does not lock or acquire the input frequency after trying various search window sizes and sample rates, the test output will print that the counter could not find the particular frequency and proceed to the next test frequency.

The counter check program, written for the HP-26/36 controller(s) in HPL language, is given in Appendix O, along with a printout of a sample test data sheet and the diagram of the test configuration.

Cable Calibration Check: Functional Operation (Giga-tronics only)

This test is not covered by the equipment specification because the cable calibration is an added feature of the Giga-tronics 1026. Since it is available and will be used when the units are deployed in the Fleet, verification of its proper operation is necessary. The program written for this test tells the operator exactly what to do on the UUT to perform the cable calibration measurement. After this is completed, the cable is removed from the internal power meter of the UUT and attached to the power sensor of the HP-436A power meter. At this time, a level accuracy test (see Output Level Accuracy test above) is run on the UUT as if the sensor were connected directly to the RF output connector. If the UUT is performing as it should, the power loss in the cable will be compensated for automatically by the UUT, and the plot of the output level will look similar to those shown in Appendix B/C. The only precaution here is that the levelled power asked for at the end of the cable must not require an output power from the UUT greater than it has available. This would result in an unlevelled condition in the leveling loop.

A sample plot from this test, a listing of the program, and a diagram of the test configuration are given in Appendix P. The program is written in HPL language for the HP-26/36 controller(s) and requires approximately 10 minutes to complete.

SUMMARY AND CONCLUSIONS

This report summarizes the detailed operation of the sample lot test procedures used as the accept/reject criteria for the Navy's new synthesized microwave signal generators manufactured by Systron-Donner, Inc. and Giga-tronics, Inc. For those desiring to use these procedures, the appendices give a detailed program listing as well as the test equipment configuration for each test.

These procedures have been used with great success at the Naval Research Laboratory to conduct sample testing of production lots since September 1982. They will continue to be employed in this same capacity and will be expanded as required.

These test procedures represent a new level of quality in the ability of the Navy to test and evaluate the performance characteristics of its synthesized microwave signal generator assets. In several areas they exceed the manufacturers' capabilities to measure the performance parameters of their equipment.

The use of the Hewlett-Packard Model 8566A Spectrum Analyzer and the virtual elimination of the need for subjective judgments on the part of the test operator have reduced test time requirements significantly (5:1 conservative estimate). At the same time, the very highest degree of accuracy is maintained.

These test procedures clearly demonstrate the advantages of performing complex testing using a central processor/computer connected via an IEEE-488 interface bus to the test instrumentation. The most important advantages are:

- (1) Test results are precisely and accurately documented.
- (2) Test procedures are well defined and standardized.
- (3) Test time is significantly reduced.
- (4) All data reduction calculations are done precisely and accurately according to data reduction algorithms.
- (5) The training and experience required for a test operator is significantly reduced.

ACKNOWLEDGMENTS

The authors gratefully acknowledge the support of Mr. L. Shoemaker of the Naval Electronic Systems Command and the engineering staffs at Giga-tronics, Inc., and Systron-Donner, Inc., for their attentiveness and technical discussions.
