ABSTRACT

The results of selected static structural tests of the Aluminum Ship Evaluation Model are presented. The data are documented in tables and figures. Background history, preliminary preparation, and significant accomplishments leading up to and during the static tests are included.

ADMINISTRATIVE INFORMATION

The work described herein was performed by the Ship Structures Division, Code 1730, of the Structures Department, of the David W. Taylor Naval Ship Research and Development Center (DTNSRDC). It was sponsored by the Naval Sea System Command (NAVSEA 05R) as part of the Structures Subproject SF43422 of the Ships, Subs, and Boats Exploratory Development Program Element (62543N). This document fulfills FY83 Milestone No. R10 of Goal and Objective No. 150-200. Overall program management was provided by J. E. Gagorik, NAVSEA 05R26.

INTRODUCTION

With the anticipation of increased use of aluminum in ship structures and an introduction of new ship hull configurations, a need was realized to study the performance of large scale complex structures under realistic controlled load conditions. This need included the validation of structural performance through large scale structural testing, the application of life cycle experimental techniques for naval ships, and the development of a validated technology base of aluminum-hulled, ocean-going ships. To achieve these goals, an all-aluminum ship model was fabricated, and an extensive large scale evaluation program was initiated in the early 1970's. This is the only time the Navy had the benefit of testing a large scale model of a surface ship structure. This method of testing is not unique, since the approach is frequently used by the aerospace industry with considerable confidence and success.

In order to fulfill the primary objective of large scale validation, a number of areas were addressed: (1) a method of applying loads to a large scale model and of obtaining stresses in the structure similar to those in a full size ship at sea; (2) a method to determine the instrumentation required to monitor primary, secondary, and tertiary stresses; (3) simulation of service loads and the effect of the

simulation on the test results; and (4) automatic control of the load, as well as a means of monitoring strains during testing.

A number of supporting technologies were used during the large-scale validation program. Analytical methods such as finite element analysis, rigid vinyl modeling, and crack-growth analysis are three examples. As shown later, comparing the results from these analytical techniques to large scale test results helps verify those methods.

Three major needs existed at the time for obtaining an aluminum technology base for U.S. Naval applications. First, there was a substantial lack of service experience for large aluminum-hulled ocean-going ships. Second, there was a definite interest, at that time, in advanced Navy vehicles (high performance ships) such as planing craft, hydrofoil craft, hover craft, and surface effect ships. In order for this type of ship to successfully perform its mission, it must have lightweight systems. Since one-third to one-half of the ship's weight is in the structural system, the selection of a high-strength, low-weight hull material such as aluminum was reasonable. The third and final reason was the Navy's potential interest in a fast, aluminum destroyer escort (DE) in the 2000-ton, 300-ft size range. This interest was based on an economic advantage of aluminum over steel for life-cycle costs of ships in this size and performance range.

For these reasons (large scale validation and aluminum technology base), an all-aluminum, 85-ft-long model of a destroyer escort was designed and built to be both statically and cyclically tested.^{1*} This Aluminum Ship Evaluation Model (ASEM) was originally designed as a 300-ft, 2200-ton all aluminum DE with integral, load-bearing superstructure. Figure 1 shows a profile view of the original design. The 300-ft size was scaled down to one-third size, resulting in a 100-ft long structural scale model, which was further reduced by eliminating 15 ft of nonstructural bow section. For economy, the 03 deck was also eliminated. Figure 2 shows a view of the model prior to load frame installation.

After preliminary design by NAVSEA design personnel, and detail design at Hunters Point Naval Ship Yard, construction began in 1974 by Tacoma Boatbuilding Co., Inc. The model was eventually shipped to the Structural Evaluation Laboratory at

*A complete listing of references is given on page 19.

DTNSRDC for load frame installation, receipt inspection,* and instrumentation.** All of these were required before testing could start. The planned testing included static tests under various combinations of loads to determine basic load, stress, and deflection behavior; and cyclic testing to determine long-term fatigue behavior.

Static testing began in early 1977 and continued for the remainder of the year. It wasn't until 1979 that cyclic testing was initiated. Testing was completed in November of 1981 after one million load cycles had been applied to the model.

Much time and effort had been expended throughout the duration of the project. It is not the intent of this report to go into the details of all aspects of the ten year project. (Appendix A shows the chronology of ASEM major events up to static test completion.) Rather, the report summarizes the results of static test and strain data analyses. In addition, the "lessons learned" during the test process are highlighted.

Subsequent comprehensive reports will cover material characteristics,² structural design,³ aluminum ship fabrication,⁴ and maintenance and repair.⁵

STATIC TEST PROCEDURE

After several years of test preparation, the ASEM static testing began in March 1977 and was completed by December 1978. Testing was in three parts: (1) vertical bending, (2) lateral bending, and (3) combined vertical and lateral bending. The bending moments were applied through 13 load frames along the length of the model. Two load frames, one at Bulkhead 24 and the other at Bulkhead 86, were fixed in space and the remaining 11 load frames were movable (allowed to displace with load). Two double pin joints were used in the connection of the frame, load cells, and hydraulic actuators, thus permitting rotation about three axes. Figure 3 is a typical load-frame configuration. At each load frame, one starboard hydraulic actuator or jack and one or two keel jacks (coupled with closed-loop, feedback system load cells) were used for load application. Table 1 lists the load cell's channel numbers and their location on the model.

*Johnson, R.E., "The Aluminum Ship Evaluation Model (ASEM) Receipt Inspection," reported informally as Enclosure (1) to DTNSRDC ltr 80-173-22 (15 Feb 1980).

**Johnson, R.E., "The Aluminum Ship Evaluation Model (ASEM) Instrumentation," reported informally as Enclosure (1) to DTNSRDC ltr 80-173-158 (17 Oct 1980).

The movable frames mentioned earlier were made up of 2, 3, or 4 semirigid parts depending on the frame location. The frames were held to the ASEM hull by the clamping action of the bolted-together parts against rubber strips that were glued to the hull and deck plating. In addition, small aluminum blocks with steel rollers installed were welded to the hull to prevent fore-and-aft motion of the load frames relative to the model. A pad pressure of approximately 5 psi was developed in the rubber due to the clamping action of the frame. The actual configuration of the rubber padding evolved through a lengthy analytical and experimental process which was aimed at keeping tertiary stresses in the stringers and plating below about 4 ksi under maximum load. The final pad configuration used is shown in Figure 4. The rubber strips were glued to the plating directly outside of the bulkhead plating and longitudinal stringers. These external locations were determined by visually locating plate distortion due to the internal fillet welds. The visual method of locating bulkhead plating centerlines can have an error up to 1/16-in. but is as accurate as other methods, such as ultrasonics.

The static loads were applied in an incremental fashion from 0 up to 80% of maximum positive load ($+0.8 P_{\max}$) in $0.1 P_{\max}$ increments, back to 0 in $0.1 P_{\max}$ increments, to $-0.8 P_{\max}$ in $0.1 P_{\max}$ increments, and back to 0 in $0.1 P_{\max}$ increments. This gave a total of 38 load levels for each test part, including the initial zero, final zero, system lock and unlock, and lateral offset.

Each test was performed enough times to establish repeatable linear strain response with load. A complete listing of the static tests is given in Table 2. During each static test, 1800 strain channels were recorded at each of the 38 load levels. An instrumentation limitation existed such that only 600 channels could be monitored at any one time. This required switching three banks at each load level to obtain the strain readings. The linearity in load versus strain response and, thus, the basic stress sensitivities (numbers of pounds per square inch per unit load application) were required for the cyclic testing. Next, 600 channels of the 1800 channels recorded during the static test were chosen for the cyclic test. These 600 channels were comprised of crack gages, gages reading high strains due to geometric discontinuities, and gages in the 3/5-length region that would accurately define the combined vertical and lateral midship bending moment as a function of time. More details are provided in a report⁶ on the cyclic test results.

After the repeatability between like test conditions was established, one complete set of data from each of the four test conditions (vertical, lateral, 60° combined, and 240° combined) was further analyzed for statistical information (Table 3). Tables describing these data analyses are found in Appendix B; associated strain data plots are found in Appendix C. Vertical-bending response slope, lateral-bending response slope, correlation coefficient, standard deviation, and predicted minimum and maximum strains were calculated for each gage for each test condition. A comparison was also made between bending response slopes for various tests, and the most repeatable gages were identified for the cyclic test.

STATIC TEST LOADING

The incremental loading magnitudes used in the static tests were directly related to those of the cyclic test. In order to better understand how these were determined, a brief explanation of the load spectra is warranted.

The development of a design load spectrum relied on factors which influence a ship response in a seaway. A ship's characteristics determine how that ship will perform for operating and wave environment conditions as defined by the ship's mission. Prediction of ship structural performance under lifetime loading is based primarily on the results of full scale trials on similar ships and related model tests.

The basic spectra to be used for the design of a 300-ft aluminum ship were developed in Reference 7. The spectra are for vertical and lateral (or athwartship) bending moments (BM) defined amidships. The vertical spectrum combines the ordinary wave (OW) or low frequency hog-sag (H-S) BM cycles shown in Figure 5 with the vertical dynamic or whipping BM cycles from Figure 6. Reference 7 discusses the method of combining the high frequency whipping cycles with the OW cycles to develop the vertical lifetime spectrum (Figure 7).

The basic vertical spectrum, in terms of H-S vertical bending moment, is listed in Table 4 as determined from Figure 7. A cycle consists of zero (0) to H (hog) (or S (sag)), through 0 to S (or H), and back to 0. As discussed in Reference 7, the whipping cycles are superimposed onto the OW cycles but only add a significant number of cycles to the high load end of the spectrum. The superimposed whipping

causes the H-S moments at the high end of the curve to be unsymmetrical about zero or stillwater. The basic vertical spectrum was truncated at a BM of 3.75×10^3 ft-tons (1 ton=2240 lb/ft) based on results of fatigue crack growth sensitivity studies.* A total of 24.8×10^6 cycles represents the total cycles for a ship lifetime of 20 years, seven of which are active at sea.

The maximum BM shown in Figure 7 is 80×10^3 ft-tons corresponding to the highest (10° or 1 time) response to waves. The maximum BM for the model is obtained when that value is multiplied by the cube of the model scale. The ASEM bending moment for static testing is simulated by applying test loads as shown in Figure 8. The calculated loads at each hydraulic actuator to be transmitted to the model during each load level are given in Appendix D for the four types of tests completed.

A lateral moment cycle is associated with each vertical moment cycle. Therefore, the number of vertical and lateral cycles are the same. The lateral BM spectrum is assumed to be the same as the vertical, except the maximum lateral BM, 40×10^3 ft-tons, is but one-half of the maximum vertical BM.⁷ This is a conservative assumption. Half of the lateral cycles lag the vertical by 60° and the other half lag by 240° . This is so because half the time one side of the ship is assumed to be the weather side and the other the leeward side.

As discussed in Reference 7, the BM spectra, vertical and lateral, are not exactly symmetrical. For most load levels the effect of this mean level is insignificant on structural life. Levels at and above the 90% load level are exceptions to this. The maximum whipping for these conditions combine with the OW bending moment such that the distribution of combined BM is 60% sag and 40% hog.

INSTRUMENTATION

A total of 1800 foil-type strain gages were installed on the ASEM for measuring applied strains (stresses were evaluated from these measured strains) and 28 linear potentiometers were installed for measuring deflections. Details of the strain and deflection measurements are discussed later. The purposes of the strain gage instrumentation were:

1. To measure stress distributions throughout the hull and superstructure to verify analysis and determine stress gradients.

*Marchica, N. V. and F. F. Borriello, "Fatigue Load Spectrum for the Aluminum Ship Evaluation Mode," Technical Memorandum TM 76-173-25 (Dec 1976).

2. To measure stresses arising from the simulation of loads.
3. To measure local stress concentrations for input to fatigue and crack growth analyses.

To meet these objectives the following analytical and experimental procedures were used for determining strain gage locations:

1. Reproduction of all strain gage locations used for the static evaluation of a rigid vinyl model (RVM) of the ASEM shown in Figure 9. (The ASEM RVM resulted from the modification of an existing RVM of a planing craft with identical hull form. The main deck and deckhouse of the RVM planing craft were replaced with a scaled version of the ASEM structure.)*

2. Extension of longitudinal and transverse gage locations from item 1 above to more accurately predict the longitudinal and transverse stress distributions.

3. Location of stress concentrations based on engineering judgment for areas of expected maximum stress.

4. Utilization of the NASTRAN finite element model (FEM) output to supplement items 2 and 3 above. A discussion of this model is found in the next section.

Appendix E contains details of the strain gage specifications as well as location nomenclature used to locate gages on the model.

Data recording capability was provided by a Xerox 550 computer. Signal conditioning and calibration for each strain gage channel was included in the software of the computer and separate calibration and conditioning was not required. As mentioned earlier, 600 channels were read by the computer at a given time. This meant that, to record the 1800 channels used for the static test, switching was required twice during the test. Each channel was sampled many times per second, an average was calculated and recorded. Recorded data were stored on magnetic tape for subsequent on-line or remote processing.

*Rodd, James L.; Ford, Harry M.; Johnson, Robert E.; "Rigid Vinyl Model Development of Structural Modifications for the Aluminum Ship Evaluation Model (ASEM)," DTNSRDC Technical Memorandum TM 80-173-1 (Sep 1980).

FINITE ELEMENT ANALYSIS

An elaborate NASTRAN finite element model (FEM) was made of the ASEM (see Figure 10). It was composed of 6000 elements and 7500 degrees of freedom. Because of the great expense involved in running an extensive finite element model, structural symmetry was utilized wherever possible. For simplicity, the stiffeners were "smeared" into the plate elements. The loads for the FEM were applied at grid points which were located along the frames where the actual loads were applied to the ASEM. The hatch openings were not extensively broken up into small elements describing exact geometry. Three types of loading conditions were applied to the FEM of the ASEM: vertical hogging loads (Force 1), vertical sagging loads (Force 2), and lateral loads (Force 3). As might be expected, a large amount of data was produced. Throughout this report, stress values obtained from the FEM analysis supplement many of the figures showing stress plots.

Several generalized findings can be gleaned from examination of the data obtained from Force 1 loading (corresponding to 80 percent BM loads):

1. Between Bulkheads 32 and 48, the main deck exhibits moderate stresses (6 ksi tension) due to longitudinal bending.
2. Between Bulkheads 48 and 64, the 01 level longitudinal bending stresses reach 9.3 ksi tension.
3. Between Bulkheads 40 and 64, the stresses near the gunwale approach 5.6 ksi tension, and the stresses at the main deck centerline approach 5 ksi tension.
4. The maximum stress at the keel was 7.5 ksi compression at Bulkhead 56.
5. Between Bulkheads 16 and 40, the hull above the chine exhibits high shear stresses (5.5 ksi).

ASEM DEFLECTION

Before the static tests were conducted, linear potentiometers were positioned along the length of the ship corresponding to load cell locations. As the model was vertically and laterally loaded for each test, the resulting displacements were monitored. It was important that the structure on which the potentiometers were attached be rigid relative to the model, and that the potentiometers be firmly attached. If this were not the case, the potentiometers could possibly move and cause erroneous deflection readings. Appendix D contains the deflections obtained from the four static tests on which the data analyses are based.

A ship at sea experiences a hogging (or hog) condition when it is positioned on the crest of a wave at midships, thereby causing the forward and aft ends of the ship to displace downward. A sag condition results when the ends of the ship are on the crests of two successive waves, and midships is at the trough. For the ASEM, a vertical hog condition was achieved when the hydraulic actuators near midships were extended. Since the lateral jacks were positioned on the starboard side of the model, a lateral hog condition resulted when the jacks at midships were extended thus causing midships to move to port.

Plots of the model displacements at maximum static test load (80%) for Tests 1, 3, and 4 are shown in Figures 11, 12, and 13, respectively. At the midship keel (near Bulkhead 56) the maximum hog to maximum sag displacement was approximately 1.5 in. Test 2 was the lateral loading test. As seen in Figure 14, at midships (near Bulkhead 56) the displacement from maximum lateral hog to maximum lateral sag was approximately 1 in.

HULL-DECKHOUSE INTERACTION

Normally, a ship is designed based on only the hull longitudinal structure (shell plating, decks, longitudinal bulkheads, etc.) resisting the loads created by the sea environment. Actually, however, the deckhouse may act as an integral part of the hull in resisting these loads. Depending on the size of the deckhouse and the way it is attached to the hull, the loads or stresses in the deckhouse may be substantial. A long deckhouse of one level with no expansion joint will result in large stresses both on the upper deck and house side.⁸ As expansion joints are added to the deckhouse, the magnitude of stresses in the deckhouse will generally decrease. Stress levels in the section near midships will remain about the same. Indeed, deckhouses may be fully or partially effective in resisting bending loads. This reality is becoming more apparent to the Navy as ship classes such as FFG-7 and DD-963 with continuous aluminum deckhouses become older and experience cracking problems due to primary bending loads absorbed by the house.

In the case of the ASEM, the hull and deckhouse were fabricated separately. They were then shipped to the test facility where the deckhouse was welded to the hull. Also, two 3/16-in. thick, 4-in. wide flat bars were welded to the upper surface of the main deck at Bulkheads 32 and 92 (front and rear of the deckhouse).

These flat bars were attached to the deck by fillet welds at both the forward and aft ends (one bar on each end of the deckhouse) (see Figure 15). The attachment locations of these bars were determined by the length dimension of the deckhouse. The distance between Bulkheads 32 and 92 above the main deck was approximately 4-in. greater than the distance between the bulkheads below the main deck. Therefore, the forward-most and aft-most bulkheads that were above the main deck did not exactly line up with those below deck. Also, this type of offset was true for a number of other deckhouse bulkheads. Table 5 summarizes the bulkhead misalignment. Note that the greatest misalignment was at Bulkheads 32, 86, and 92. This was a concern mainly because the model was loaded through the bulkheads. However, as it turned out, this offset did not appear to create any local structural problems such as buckling.

The joint details between the main deck and the bulkheads interior to the deckhouse were somewhat different than those at the front and aft ends of the deckhouse (see Figure 16). The bulkhead plates were fillet welded forward and aft to the upper surface of the main deck where they landed. A 3/16-in.-thick gap was left between the main deck and bulkhead stiffeners (the stiffeners were on either the forward or aft side of the bulkhead). A 3/16-in. thick, 2-in. wide flat bar was then positioned between the stiffeners and deck. The stiffeners were welded to the flat bar and the flat bar was fillet welded to the deck at the accessible edge. Based on inspection of test results, this type of detail proved adequate during testing.

The following section contains a detailed explanation of the hull deckhouse interaction and subsequent high strains.

FASHION PLATES AND ACCESS HATCH OPENINGS

High stresses at the forward and aft ends of the deckhouse and discontinuities near midships can eventually cause fatigue problems. These areas of concern are shown in Figure 17 as A, B, and C (port and starboard). Also, high stresses at access hatch openings are of concern.

The discontinuity at Location A creates high shear forces at the forward end of the deckhouse, and acts as a stress raiser for the local deckhouse structure. In the case of the ASEM, the integral hull-deckhouse increases the effective moment

of inertia of the hull. Stresses on the order of 15 to 20 ksi for the 80% maximum BM condition were monitored during the static (precyclic) tests. This area as well as other highly stressed areas in the deckhouse were of major concern. It was felt that the high stresses in the as-fabricated structure would eventually cause premature cracking. In April 1977, the decision was made to initiate an extensive study of the stress areas of concern by use of a rigid vinyl (PVC) model of the ASEM. Details of the results of these tests were reported informally.* Basically, a number of structural modifications were made to reduce strains in the PVC model such that similar modifications to the aluminum model would do the same. Table 6 summarizes the PVC test results for a number of stress areas of concern as well as for the eventual ASEM structural modifications. For the most part, side shell doublers and coaming doublers were used at the hatches. Port and starboard fashion plates were used at the intersection of Bulkhead 32 with the main deck, and at the intersection of Bulkhead 56 with the 01 deck. The fatigue performance of these structural modifications are covered in a report⁶ on the ASEM cyclic test results.

Most of the access hatch openings in the deckhouse sides were strain gaged to monitor any unusually high strains during the static tests. Since high strains were recorded in some instances, the possibility of premature fatigue failures during the cyclic testing existed. As mentioned earlier, the reduction of strains in the rigid vinyl model hatch opening were examined, with the result that structural modifications to the ASEM were recommended. The locations of the deckhouse side hatch openings are shown in Figure 18. A typical hatch opening is shown in Figure 19.

The decision was made to increase the thickness of the plate material immediately adjacent to the hatch coaming. A doubler plate (equal in thickness to the deckhouse side plating) was plug welded to the existing plate along the stiffeners, as well as fillet welded at the edges of the new doubler plate. The edges were located at the adjacent frame or bulkhead and at the main deck and 01 deck level. The coaming thickness was increased (doubled) by welding an additional coaming of the same thickness and width to the existing coaming. The resulting structural modification to the hatch openings are shown in Figure 20.

*Rodd, James L. et al., "Rigid Vinyl Model Development of Structural Modifications for the Aluminum Ship Evaluation Model (ASEM)," reported informally as Enclosure (1) to DTNSRDC ltr 80-173-158 (17 Oct 1980).

The average stress reading associated with a hatch coaming gage was over 10 ksi; indeed, one reading was as high as 15 ksi. Static tests run after the modifications of adding a doubler plate and coaming doubler indicated lower strains at similar locations. This would certainly indicate that the problem of premature fatigue cracking would be alleviated. The behavior of this type of "fix" relative to fatigue is discussed in another report.⁶

In addition to high strains (stresses) at the coamings, the plating adjacent to the coaming also had high strain readings. These areas were not extensively regaged after the doubler plate additions; however, those that were gaged showed a substantial reduction in stress. In an actual design, implementing a fix such as the one completed with the coaming would probably be necessary. However, instead of welding two pieces of coaming together to obtain a certain thickness, a single piece of the desired thickness should be used.

STRAIGHTNESS OF BULKHEAD STIFFENER FLANGES BETWEEN MAIN DECK AND O1 DECK

Since the model was loaded through its bulkheads, the straightness of the bulkhead stiffeners were of concern. Excessive stiffener warpage might have resulted in local or total buckling of the bulkheads during testing. Therefore, a survey of the degree of warpage of the stiffeners relative to vertical was conducted (Table 7). Bulkheads 32, 40, 48, and 80 had the least average warpage of the stiffener flanges, and it was all in the forward direction. Bulkheads 56, 64, 86, and 92 had the greatest average stiffener flange warpage, and here it was all in the aft direction. One stiffener flange on Bulkhead 92 was warped as much as 0.75 in. Additional information can be found in a report⁹ on stiffener and bulkhead deformation surveyed during the cyclic testing of the model.

SPECIAL CONSIDERATION FOR ASEM STATIC TESTING

With a test of this physical size and complexity, not all problems could be foreseen. In most instances, with careful thought, potential problems can be averted by modifications to the test fixture, test procedure, or model. When possible, these modifications or changes should be done in such a way as to not adversely

effect the test results. A number of "lessons learned" by the authors relative to how this information can benefit future tests of a similar nature are highlighted next.

COUPLING OF LOAD FRAMES/STRUCTURALLY REINFORCING LOAD FRAME

Originally, the test fixture was designed so that a number of load frames were longitudinally coupled together at the centerline (load frames at Bulkheads 64, 72, and 80). However, this meant that if one of the load frames became displaced fore or aft from the desired plane of loading, the remaining attached load frames would also displace. Lateral buckling of the originally designed load frame couplings caused this kind of problem. The solution was to not have the load frames coupled, and to strengthen the lower section of the load frame by welding steel plates between the edges of the flanges. Thus, the I-Beam effectively became a box beam, thereby inhibiting lateral buckling or tripping of that portion of the load frame.

REDESIGN, FABRICATION, AND FOAM REINFORCEMENT OF PARTIAL BULKHEAD 72

The "as built" frame at Bulkhead 72 was not constructed to carry the 95,000-lb load needed to insure the proper BM through the model during testing. The area between Bulkheads 64 and 80 was designated for the engine room and, therefore, this area was initially open. If the space was to remain as built, the load applied would then buckle and collapse the frame. Therefore, a redesign was required. Because of the restraints imposed by the access to the model, the design took the form of truss-type framework (Figure 21). The redesign was constrained in the sizing of members by (1) the openings built into the model to supply materials into compartments and (2) by allowing the members to carry a maximum of only 6 ksi of stress.

A frame analysis using the computer program STRESS¹⁰ was used in the design of the "framed bulkhead." A final design was determined and construction started in December 1976. Figure 21 shows the framework used in the ASEM at Bulkhead 72, both as originally built and as a redesign.

An additional problem recognized was that the floor at Frame 72 had no access to it, except for two 6-in.-diameter holes, and thus it could not be stiffened by welding on stiffeners. The floor was made of 1/8-in. plate and, unless it was stiffened, it would have buckled under the applied loads.

One solution to this problem was to use syntactic foam and fill the compartments under the innerbottom on both sides of Frame 72 (between Frames 69 1/2 and Frame 74 2/3) as shown in Figure 22. This foam was chosen for its light weight, ease of installation, and ability to sustain compressive loads. A full size wooden model was constructed to evaluate the procedure to fill the compartments with the foam and to determine the temperature produced by the foam as it cured. It was necessary to know the temperature because aluminum can become sensitized above 200°F and is then susceptible to stress corrosion cracking. Thermocouples attached to strip recorders were used to determine the curing temperature and to evaluate the filling procedure. Plexiglas was used on one side to act as a floor.

There were two tests. The first was to fill one side with the syntactic foam, and to pour the necessary resin all in one pour. The temperature given off during this test was approximately 206°F, which was unacceptable.

The second test was similar to the first except that the resin was poured in increments of 5 gallons per day. Three days were necessary to complete the procedure, and four pours were required to fill a compartment on either side of the bulkhead and port or starboard of the Center Vertical Keel (CVK). The maximum temperature was approximately 130°F. Although this temperature was acceptable, there was doubt as to whether a good bond had been made between the different pours. Also, there was a residual film of resin on the upper walls after the resin had settled to the bottom. A line of air pockets could be seen through the plexiglas floor where the different pours had settled.

Therefore, the procedure in the aluminum model was to pour two compartments (which were diagonal to each other) at a time. The resin was to be poured in the hole nearest to the keel. Thermocouples were placed in the compartments filled on the first day. The temperature recorded was below 100°F, which was an acceptable temperature.

Because the foam was poured into the center section, the resin tended to gel before it could spread outward to the outboard section. An attempt was made to fill the outboard sections by pouring resin in the outboard holes. It seems that little resin went into these confined areas and a possibility exists that the floor at Frame 72 may have been unsupported on the outboard edges. This was not a problem, however, since the unsupported depth of floor plating at the sideshell attachments was small enough to insure that no structural damage was sustained during either the static or cyclic tests.

CONCLUSIONS

The initiation, execution, and completion of all research associated with the Aluminum Ship Evaluation Model program has marked a significant milestone in ship structural research. This has been the first and only time that the Navy has had the combined resources for performing extremely large, complex, and controlled laboratory experiments on complete ship structures. Many new technologies were explored and many lessons learned. The proven capability now exists, in terms of facilities, software, hardware, and experienced personnel, to perform future tests of this nature for purposes of specific design validation efforts or advanced development. Future tests should be able to be performed using less time and resources due to the significant experience gained through these ASEM tests.

Specific detailed conclusions regarding the ability of aluminum to perform as a hull material cannot be made in a total sense without examining the results of the cyclic test. From a static standpoint, the aluminum-hull-girder (ASEM) behaved in accordance with beam theory and remained linear throughout the range of loads and stresses applied. Therefore, from this test it can be concluded that aluminum is an acceptable material for hull girders, from a quasi-static load viewpoint, when designed to maximum stress values consistent with those applied to the ASEM. Additional conclusions regarding specific geometric behavior will be left to the reader. This is done to allow the reader to use the vast amount of data presented herein to draw specific conclusions which concern his detailed problem. A summary of the major, more general conclusions follows.

LOADING METHOD

The method used in applying loads to the ASEM is unique in large scale testing. Normally, in the aircraft industry large-scale static tests are performed with distributive pads or bladder loading, and cyclic tests are performed with "wiffle-tree" arrangements. These methods were not feasible for the ASEM tests and, consequently, the load-frame or load-ring arrangement was developed. In spite of some initial problems, this loading method proved very successful. Lateral instability of loading-frame lower-transverse members was easily corrected by making the I-beams into closed cells and this problem could have been avoided if all out-of-plane deflections had initially been considered. Fore-and-aft restraint of the load frames relative to the model was required to maintain their alignment and stability. This became even more apparent the longer the testing progressed, due to rubber-pad aging and creep. Tying the frames to each other proved unsuccessful; however, attaching small local restraints to the hull allowing them to provide unattached stops to the load frames proved very successful. The method of loading through rubber pads into the bulkheads worked well.

COMPUTER CONTROLS AND SAFEGUARDS

For the most part, these systems also worked well. Initial problems in debugging a new system were technically overcome. Desired loads were achieved within a few percent. Computerized data acquisition and analysis performed well, although long term stability and system noise did present problems. The development of more sophisticated software and hardware as the test program continued, essentially resolved all earlier problems.

DECKHOUSE BEHAVIOR

A long continuous deckhouse, like the one on the ASEM, is very effective in absorbing primary hull-girder bending loads. This can be beneficial in that it reduces primary hull stresses; however, significant primary stresses are then absorbed by the house. This in itself is not necessarily a problem if the deckhouse is properly designed to withstand those stresses. The ASEM deckhouse, on the other hand, was not properly designed to withstand the magnitude of primary stress that it eventually experienced.

The deckhouse was designed using conventional Navy practice, which, up to the time of the ASEM design, had proven acceptable. At that time, little or no experience existed with long, continuous, integral deckhouses. Structural discontinuities, terminations, transitions, and conventional structural details as originally designed in the ASEM deckhouse proved inadequate. Smaller scale modeling and analysis resulted in structural changes such as fashion plates, inserts, and extended coamings which did significantly reduce high stresses when applied to the ASEM. Many of these changes would not be considered "conventional" Navy practice.

ANALYTICAL AND SMALL MODELING STRAIN PREDICTIONS

A comparison between measured strains on the ASEM, the RVM, and predicted values from the finite element model shows generally excellent agreement. In an overall sense, the behavior of the integral deckhouse can be properly predicted using analytical and small modeling techniques. For local detail stresses at discontinuities and notches, a parallel conclusion cannot be made. The element sizes used for the NASTRAN model and the gage sizes used on the RVM preclude any detail stress comparison. The RVM did, however, more accurately predict stresses in areas of high gradients than did the NASTRAN model used in our analysis.

The extensive amount of data presented in this report can be used for analyzing a large number of related problems. For example, stress gradients around openings and ways of reducing them can be examined utilizing ASEM data. Load/stress sensitivities for many details and local geometries can be examined. Combined stress effects of vertical and lateral bending can also be analyzed. The reader must be careful, however, when using any large-scale test data, to ensure that any local effects due to testing, or anomalies due to load simulation have been taken into account. In the case of the ASEM static tests, these cautions would apply mostly to bulkhead stresses.

ACKNOWLEDGMENTS

The authors thank the numerous individuals and organizations that were involved with the ASEM project throughout the years. We would especially like to thank DTNSRDC's Code 1706 for their assistance, and the many test mechanics and Cooperative Education students who have worked on and contributed to this project.

APPENDIX A
CHRONOLOGICAL FOLD-OUT OF ASEM MAJOR EVENTS THROUGH
STATIC TEST COMPLETION

This appendix contains a chronological summary of the major events concerning the Large Scale Validation Program with the main emphasis on those items which affected the ASEM (see Figure A.1). The chronology begins with the preparation of the preliminary design by NAVSEA personnel in late 1972; then the construction period and delivery of the ASEM in 1974; the load frame and gage installation spanning from 1975 to 1977; the first static test in March 1977; and, (finally) static test completion in late 1977. Preparations for the cyclic tests were begun in early 1978 (a similar chronological summary is found in the report⁶ which includes the results of the cyclic tests run from 1978 to 1981).

APPENDIX B
STRAIN DATA OF FOUR ANALYZED STATIC TESTS

GENERAL

During the static tests conducted on the ASEM, data were stored on magnetic tape for future computer data analysis. After preliminary analysis of the data, four tests with the "best behaved" data were chosen for extensive statistical analyses. Tables B.1 through B.4 summarize the results of these analyses. Throughout the analyses, the assumption is made that a linear relationship exists between load and resultant strain. To aid in interpreting the tables, an explanation of each table is given with emphasis on the explanation of column headings.

Prior to static testing, a system was devised which assigned an alphanumeric character to gages based on the gage location on the model.* In order to better understand gage locations described by the alphanumeric character used in Tables B.1 through B.4, the relevant portions of an informal report were extracted and included in Appendix E for referral.

The first three columns of Tables B.1 through B.4 are all exactly the same. The first column, titled GAGE NUMBER, is a number 1 through 1800 referring to a unique channel and, therefore, to a unique strain gage. As mentioned previously, GAGE NAME refers to the alphanumeric character used to describe the strain gage location. The third column, POSITION, is comprised of three values. The first value is the number associated with one of ten strain bridge completion panels located beneath the model on the test bed floor. The second value is the particular bank (blank, A or B) in each panel. The third value is the strain channel associated with each panel and each bank. This number varies from 1 to 60. Thus, for any one specific strain channel, the GAGE NUMBER, GAGE NAME, and POSITION are individually unique but all three represent one particular strain channel.

*Johnson, R.E., "The Aluminum Ship Evaluation Model (ASEM) Instrumentation," reported informally as Enclosure (1) to DTNSRDC ltr 80-173-158 (17 Oct 1980).

TABLE B.1 - STATISTICAL RESULTS FROM ASEM STATIC TESTS WITH INDIVIDUAL VERTICAL AND LATERAL LOADING

The statistical analysis of the strain gage data obtained from the test on 22 September 1977 is presented under the portion of Table B.1 entitled VERTICAL LOADING ONLY. The data analysis of the test on 28 October 1977 is under LATERAL LOADING ONLY. As they imply, only vertical loads were applied to the model on 22 September and only lateral loads were applied on 28 October.

The SENSITIVITY/100% is the number obtained from performing linear regression analyses on the data and extrapolating the strain at 100% maximum BM. In this case, the load and temperature are the two independent variables in the analyses. Thus, multiplying this number by a fraction representing a particular load level will give the strain for that particular load level. In actuality, since no load greater than 80% maximum BM was applied to the model during the static tests, the factor will be no greater than 0.8.

The DRIFT is an indication of the variation in the data from the theoretical straight line plot due to temperature effects over time. The results of the linear multiple regression analysis used in determining the DRIFT is in micro inches per hour of apparent strain due to thermal effects on the lead wire resistance.

In this study, the ERROR OF ESTIMATE (EOE) is the standard deviation of the variation between measured data and predicted values. In general, the smaller this number, the better behaved are the data. However, unless the change in strain resulting from change in applied load is of significant magnitude ($>50\mu\epsilon$), the EOE is not a good measure of data validity.

The CORRELATION COEFFICIENT is the quantitative measure of association between the strain and load variables, or how well a curve (straight line in this case) fits the test data. This value ranges from 0 to 1. As it approaches 1, the correlation between the data and the theoretical straight line will improve. Because of the definition of the correlation coefficient, a saturated (bad) channel will have a data value of zero (thus fitting a horizontal straight line perfectly). In this case, the correlation coefficient will have a meaningless value of 1.0.

TABLE B.2 - STATISTICAL RESULTS FROM ASEM STATIC TESTS
WITH COMBINED VERTICAL AND LATERAL LOADING

Whereas Table B.1 presented the results of the analysis of the data from the vertical-loads-only test and the lateral-loads-only test, Table B.2 presents the data analysis of the combined vertical and lateral loading test with a 60° phase lag and the combined loading test with a 240° phase lag. The ERROR OF ESTIMATE and CORRELATION COEFFICIENT are determined in the same manner as discussed previously. However, for the combined loading tests, the SENSITIVITY/100% values are obtained for the two independent variables, VERTICAL loads, and LATERAL loads.

TABLE B.3 - STRAIN SENSITIVITIES FROM STATISTICAL
ANALYSIS OF ASEM STATIC TEST DATA

This table is a compilation of the "best" data selected from Tables B.1 and B.2. The first three columns are the same as in the previous two tables. The fourth column, ASSUMED CAL identifies whether the calibration (cal) value recorded during testing was used in the analysis, or whether an assumed value was used. The strain computations are based on calibration values derived from the statistical evaluation of nine separate values. The assumed calibration value (indicated by a YES) was the average of all of the valid calibration values. For the data analyses, this was -536.9 counts per 1000µε.

The criteria of "best" data is based on the lowest error of estimate. For VERTICAL LOADING ONLY the VERTICAL SENSITIVITY, ESTIMATE OF ERROR, and CORRELATION COEFFICIENT were selected from Tests 1, 3, and 4 (see Table B.4).

TABLE B.4 - TEST IDENTIFICATION USED IN TABLE B.3

Test	Type Loading	Date
1	Vertical	9-22-77
2	Lateral	10-28-77
3	Combined at 60° Lag	10-14-77
4	Combined at 240° Lag	10-26-77

For LATERAL LOADING ONLY the LATERAL SENSITIVITY and associated ERROR OF ESTIMATE and CORRELATION COEFFICIENT were selected from Tests 2, 3, or 4. The majority of the data in Table B.3 came from Tests 1 and 2. Apparently the temperature effects for these two tests were minimized.

TABLE B.5 - COMPARISON OF ASEM STATISTICAL ANALYSIS RESULTS AND STATIC TEST DATA FROM COMBINED LOADING AT 60 DEGREE LAG

This table compares the theoretical data obtained from the data analysis with the actual test data for the test of combined loading with a 60° lag. The first four columns are the same as in the previous tables. The fifth column is the maximum positive measured value of strain and the sixth column is the vertical and lateral loads at which the maximum positive measured strain occurred. The seventh column, PREDICTED STRAIN, is the strain value which would have been predicted using the moment condition of the previous column. This strain value is determined by first dividing the two numbers in the previous column associated with vertical and lateral moment by 100; then multiplying by each appropriate sensitivity from Table B.3 and finally summing the two values.

The last three columns are the MAXIMUM PREDICTED STRAIN, the MOMENT condition at which it occurs and the actual MEASURED STRAIN at that MOMENT condition. When the MAXIMUM PREDICTED STRAIN and the MEASURED STRAIN are determined to be the same, the characters SAME are used to prevent repetition.

TABLE B.6 - COMPARISON OF ASEM STATISTICAL ANALYSIS RESULTS AND STATIC TEST DATA FROM COMBINED LOADING AT 240 DEGREE LAG

This table is similar to Table B.5 except that the comparison of the theoretical and actual data is for the test for combined loading with a 240° phase shift in the lateral and vertical loads.

TABLE B.1 - STATISTICAL RESULTS FROM ASEM STATIC TESTS WITH INDIVIDUAL VERTICAL AND LATERAL LOADING

APPENDIX C

STRAIN DATA PLOTS

The following is a discussion of the plots of strain data for several specific structural sections of the model. Appropriate strain data from rigid vinyl model tests, the finite element analysis, and beam bending theory are included for comparative purposes.

There are five basic categories of strain data plots. These are:

1. Longitudinal distributions of longitudinal bending strain.
2. Transverse distributions of longitudinal bending strain.
3. In-plane stress concentrations and misalignment strain in the bulkheads.
4. Stress concentrations due to openings in the Main Deck and 01 Deck.
5. Stress concentrations in the superstructure hull due to openings and discontinuities.

LONGITUDINAL DISTRIBUTION OF LONGITUDINAL BENDING STRAINS

Probably the most dramatic and revealing and yet well-behaved strain-data plots are those of longitudinal distributions of longitudinal bending strains. Where applicable, the plots include finite element data and rigid vinyl model data.*

Figure C.1 shows small magnitudes of strain along the centerline of the 02 Deck. Since these gages are at the centerline (on the web of the centerline stiffener), lateral loading has little effect on the strains. Included on this plot are strains at gage locations off the centerline. A quick look shows considerably higher strains further off the centerline (outboard) and, as will be shown later, plots of transverse distributions indicate this same phenomena. These low centerline strains are probably due to the relatively short length of the 02 Deck even though it is near midships. Shear in the deckhouse sidewalls caused the strain values in the 02 Deck to increase nearer the house wall.

In general, the strains measured by the gages on the webs of the 01 Deck centerline stiffeners are well behaved and the magnitudes are predictable. Midship strains at 80% maximum BM are nominally 500 μ in./in. as shown in Figure C.2. However, the

*Rodd, James L. et al., "Rigid Vinyl Model Development of Structural Modification for the Aluminum Ship Evaluation Model (ASEM)," reported informally as Enclosure (1) to DTNSRDC ltr 80-173-158 (17 Oct 1980).

gage at Frame 61 indicates a value about 25% higher than would be expected. At first glance, this data point might be neglected; however, upon looking at other gages in this area (as in Figure C.3) strains are indeed higher than would be expected. Strain readings from Tests 1, 3, and 4 were of similar magnitude, since lateral moments of Tests 3 and 4 have little effect on centerline gage strain readings.

The Main Deck centerline gages, which are located on the web and near the neutral axis of the centerline stiffener, indicate strains of near $300\mu\text{in./in.}$ near midships at 80% maximum BM (see Figure C.4). A slight increase in strain reading over what might be expected in the vicinity of Bulkhead 32 was noted. Also, the strains increased aft of Frame 103 rather than approach zero as would be anticipated. This may be related to a shift in the neutral axis location of the model due to the effect of longitudinal bulkheads in the aft end of the model. This is even more evident in the plot of the platform deck strains at the centerline.

The longitudinal strain distributions due to longitudinal bending stresses near the gunwales and under the deckhouse side wall are not as well behaved as might be expected. Figures C.5 through C.8 show strain data plots at the following locations: (1) at the port gunwale, (2) along the length of the port deckhouse side wall, (3) at the starboard gunwale, and (4) along the length of the starboard deckhouse side wall, respectively. The gages along the deckhouse side wall are located 1 in. outboard of the wall, and on the underside of the main deck (a longitudinal girder is located directly beneath the wall.) The gunwale gages are on a 2-in. wide, $1/4$ -in. thick doubler that is welded to the deck and side shell. The 2-in. length dimension of the doubler is vertical relative to the main deck.

The longitudinal distributions of longitudinal bending strain data at the platform deck centerline is shown in Figure C.9. The platform deck is near the neutral axis of the model and, subsequently, the strain readings at 80% maximum BM are nominally less than $50\mu\text{in./in.}$ An increase in strain aft of Frame 80 is evident and is due to a shift in the neutral axis of the model. With the addition of longitudinal bulkheads, the neutral axis shifted below the platform deck level thus causing strains to increase as high as $150\mu\text{in./in.}$

The inner bottom strain values for the longitudinal distribution at 80% maximum BM is shown in Figure C.10. The actual strains along the length are erratic relative to a smooth curve drawn through the data. This may be due in part to lower strains for gages located above transverse bulkheads (floors). Also, the portion of the inner bottom between Frame 69 1/3 and 74 2/3 was reinforced with syntactic foam, thereby partially explaining the very low strain reading at Frame 73. Near midships the maximum strain values during the static tests were about 300 μ in./in.

Probably the most well behaved data of the longitudinal distributions are at the keel centerline. The gages were placed on the exterior of the flat bar keel and protected with a waterproof coating. At 80% maximum BM, strains near Bulkhead 32 are slightly higher than expected. At midships, the strain value appears to peak slightly above 600 μ in./in. (see Figure C.11).

TRANSVERSE DISTRIBUTION OF LONGITUDINAL BENDING STRAINS

Five locations along the length of the model were chosen to show transverse distributions of longitudinal bending strains (these are often called "belts" throughout this report). The belts were at Frames 21, 45, 61, 73, and 95. If the model were longitudinally sectioned into eights, Frame 21 would be about 1/8 the model length from Bulkhead 8. Frame 45 is about 3/8 the model length from Bulkhead 8; Frame 61 about 1/2 or near midships; Frame 73 about 5/8 and Frame 95 about 7/8 the model length. The sections at Frames 21 and 95 include only the main deck and hull. The section at Frame 45 includes the hull and both the 02 and 01 levels of the deckhouse. The sections at Frames 61 and 73 include the hull and 01 deck level (the 02 deck terminates at Bulkhead 56).

In general, for the instances of 80% maximum BM, the magnitude of strains for the 60° lag case and the 240° lag case increased near the edge of a deckhouse external deck. In most instances, the 60° lag condition created higher relative strains on the port side than did the 240° lag condition. Alternately, the 240° lag condition created higher relative strains on the starboard side. This was due to the relative phase shift in the vertical and lateral load components.

Belt 21

The strain distribution across the main deck noticeably dropped off near the starboard gunwale (see Figure C.12). Because of the lack of data for the port side,

a similar comparison could not be made for that side. However, upon examining the longitudinal distributions for the port and starboard gunwales, the order of strain magnitudes of gages in these two areas support this drop in strain. The strain distribution in the hull is linear except near the platform deck. The drop off in strain may be due to the V-shape of the hull at this section of the model. Since the neutral axis has probably shifted up, the stresses at the deck are less than at the keel. Also, there is a substantial decrease in the section near the gunwale. This phenomenon does not occur further aft where the model sections are more box-like.

Belt 49

The section of the model at Frame 49 includes both the 01 and 02 decks. As seen in Figure C.13, there is a noticeable drop in strain as the center of the 02 deck is approached. This is due to the short deck length and the shear in the deckhouse wall. The strain distributions at the main deck and 01 deck are linear and averaged about 350 $\mu\text{in./in.}$ and 450 $\mu\text{in./in.}$ respectively. Of special interest is the strain distribution from the keel to the 02 deck. It is relatively linear from the keel to the main deck, with the lowest strain readings monitored at the platform deck level. It is obvious that the deckhouse is partially effective in picking up a portion of the load in the hull. Of questionable validity is the data point midway between the 01 deck and main deck. The drop in strain may be due to the effect of the access hatch opening immediately aft of the gage. The aftmost edge of the hatch coaming was located 21 in. forward of the gage. Also, Bulkhead 48 is located between the access hatch opening and gage.

Belt 61

The section at Frame 61 has the 01 deck as the uppermost deck, since the 02 deck terminates 50 in. forward of Frame 61 at Bulkhead 56. Both the 60° and 240° lag data at the 01 deck show similar characteristics (see Figure C.14). As the starboard or port edges of the 01 deck are approached, the strain increases significantly and strain data from gages located on the deeper girders (centerline, sixth port and starboard stiffeners outboard) were noticeably higher than for the remaining

stiffeners. The gage positioning probably resulted in the apparent discontinuities. The girders are 3 3/8-in. deep and the stiffeners are 1 3/8-in. deep with the longitudinal gages positioned about 1/2 to 3/4 in. below the bottom surface of the 01 deck for both girders and stiffeners. The gages on the girders were a good distance from the assumed neutral axis (N.A.) and the gages on the stiffeners were probably very close to the local N.A. Secondary bending effects may have resulted in higher strains in the deeper girders. Mentioned earlier were the very high strain readings near the 01 deck edges. This order of magnitude of strain (~1500 μ at 80") is also seen in a deckhouse side gage near the 01 deck.

Belt 73

The transverse distributions due to longitudinal bending at Frame 73 are similar to previously discussed belt data. The 01 deck strains are higher near the edges as shown in Figure C.15. The strain reading of the gage near the top of the starboard deckhouse sidewall is similar to strain readings at the 01 deck edge; and there is a significant drop off in strain results going down the wall to the main deck. The low strain reading midway down the wall may be due to the access hatch opening being just 30 in. aft of the gage. The main deck gages show predictable strain readings, with a slight increase in strain at the starboard edge.

Belt 95

As with Frame 21, this section of the model does not contain deckhouse structure. The strain gradients at the main deck are not as well behaved as they are for other belts (see Figure C.16). However, as expected, strains at maximum BM were no more than 200 μ .

IN PLANE STRESS CONCENTRATIONS

The majority of transverse bulkheads in the hull and deckhouse superstructure were extensively strain gaged to monitor any in-plane stress concentrations and any misalignment strains in the bulkheads during static testing. A substantial amount of data was obtained for Bulkheads 8, 16, 24, 56, 64, 80, 86, 92, 98, and 108.

The instrumentation associated with Bulkheads 32, 40, and 48 was malfunctioning during the static tests; subsequently no strain data were obtained. The bulkheads are the only component of the model not scaled by one-third. The scaled thickness was doubled to prevent premature buckling.

The majority of bulkhead strain gages read only low to moderate strain values during the tests. Excluding the channels associated with Bulkheads 32, 40, and 48, only a few were open, shorted, or erratic. Bulkhead strain data are shown plotted in Figures C.17 through C.29.

BULKHEAD INSTRUMENTATION

Bulkhead instrumentation was located to basically monitor two types of structural phenomena. Gages were located on the flanges of selected stiffeners and on the plating on the opposite side of the selected stiffeners. A major discrepancy in the magnitude of strain would imply local bending was occurring at that location. If a number of channels indicated a major discrepancy, then overall buckling of the bulkhead could have been occurring.

Gages were also located at the "hard points" on the bulkheads near the hull plating (port and starboard). This included gages at the platform deck level (upper chine), near the lower chine, near the inner bottom level, and at the keel.

The strain patterns and distribution in the bulkheads were largely a reflection of the method used to apply the loads to the model. That is, loads were directly transferred from the moveable load frames, through the rubber pads surrounding the bulkheads and then into the bulkhead plating and stiffeners.

In almost all instances, gages near the deck/rubber pad intersection read higher than those nearer the center of the bulkhead. Also, these gages showed somewhat higher strains in the stiffeners than the plate, as might be expected, since a portion of the load is also going through the plate material between stiffeners. Of the gages near the deck, the centerline gage often read the highest strain.

The strain gage rosettes located at the hard points were moderate-to-high in magnitude at the forward and aft ends of the model. The high strains in the forward bulkheads are probably related to the soft chine and high deadrise in the hull.

Except at Bulkhead 108, from Bulkhead 80 and aft, the strains at the rosette locations were quite low. The shape of the hull is much more "boxlike" along this portion of the model with two hard chines and a low deadrise. The higher strains at the hard points on Bulkhead 108 may be due to the method of loading since the load frame is bolted directly to the model. Also for Bulkhead 108, the strains near the uppermost exterior deck are quite small, which is not the case for most other bulkheads.

In general, no major bulkhead structural problems were detected as the result of the static tests. The loads were transferred into the hull through the load frames and bulkheads as expected.

STRESS CONCENTRATIONS AND DISCONTINUITIES

A number of areas in the hull and deckhouse were instrumented as areas of stress concentrations and locally high strains during the static tests. Any strain readings corresponding to a stress of 20 ksi or more at the 80% load level could potentially create early fatigue cracking problems during the model's cyclic testing. The model sections which were instrumented included numerous access holes in the deckhouse sides (both port and starboard), 01 deck access holes, main deck access holes, the port-aft corner of the deckhouse (Bulkhead 92 below the main deck) and the forward corners of the deckhouse (Bulkhead 32).

There are three access holes in the 01 deck and all three were instrumented with gages positioned on the outboard portion of the coaming. In addition, the access hole at Frame 38 1/2 had a rosette and three additional gages adjacent to the rosette. The strain in the 01 deck at Frame 38 1/2 is nominally 150 $\mu\epsilon$; however, the gage at the aft outboard corner indicates a significantly higher strain (see Figure C.30). Also, the strain gradient drops off in magnitude as the deckhouse side is approached. Figure C.31 shows high strains in the corner of the access hole coaming at Frame 46. Nominal strains at Frame 46 are about 300 $\mu\epsilon$ at 80%; however, a value of over 1200 $\mu\epsilon$ was measured during the cyclic testing. The gage at the corner of Frame 52 access hole indicates a strain only slightly more than the nominal strain of 400 $\mu\epsilon$ (see Figure C.32, locations A and B).

Five of the seven access holes in the main deck were instrumented to varying degrees. The following hatch openings were instrumented: Frame 36 port, Frame 44 port, Frame 66 1/2 starboard, and Frame 77 1/3 port and starboard.

One of the more thoroughly instrumented main deck openings was at Frame 36 port. A series of five gages were placed on both the forward and aft outboard corners of the opening (see Figure C.33). The nominal strain in this area of the main deck at the 80% load during the 60° lag test is about 400 $\mu\epsilon$. Gages adjacent to the coaming read between 500 $\mu\epsilon$ and 800 $\mu\epsilon$, and gages at the curved portion of the coaming increased to 900 $\mu\epsilon$ as shown in Figure C.33. A drop in strain occurred on the straight portion approaching the curved section of coaming and where the coaming became transverse to the primary stress direction.

The opening at Frame 44 port was instrumented similar to the opening at Frame 36 (see Figure C.34). The strain distributions are also similar. The nominal strains near Frame 44 are slightly higher (450 to 500 $\mu\epsilon$) than at Frame 36, and the strains at the curve in the coaming are near 1000 $\mu\epsilon$, as shown in Figure C.34.

There are four access holes in the main deck immediately above the engine room compartment. Unlike the two previous square openings, these are elongated in the longitudinal direction. Gages were placed only on the outboard corners of the coaming of the opening at Frame 66 1/2 starboard (see Figure C.35). Again, gages placed on the straight portion of the coaming showed strain readings which were close in magnitude to the nominal strains in that area of the main deck, as seen in Figure C.35. A sizeable increase in strain occurred in the curved portion of the coaming corner.

Gages were placed on the two outboard corners of the opening at Frame 77 1/3 starboard (see Figure C.36). The strain data are not as well behaved as those of previously discussed openings, as can be seen in Figure C.36. The data may be suspect since this opening was utilized both as a pathway for permanently installed instrumentation wiring and as access to the interior of the hull. Gages were also placed in the opening at Frame 77 1/3 port (see Figure C.37). An irregularity appears in the second gage in both series of 5 gages at each corner. If it were not for this irregularity, both distributions would be similar to what has been shown before. It is possible that instrumentation wiring was reversed for these two gages.

A number of gages were placed on or near the coamings of most of the access holes in the deckhouse side between the main deck and the 01 deck. Gages were placed on openings at Frames 33, 39, 41, 46, and 62 1/2 on the port side, and at Frames 76, 78 1/2, and 87 on the starboard side. This involved at least a series of 4 gages per coaming, placed on the center of a curved section of the 2-in. wide, 3/8-in. thick coaming. The exact positions of the gages are shown as well as the strain gradients from the static tests in Figures C.38 through C.45. As a result of high strains in many access hole coamings measured during preliminary static tests (i.e., testing prior to the four tests examined for this report), structural modifications were completed. These entailed doubling the thickness of the original 3/16-in. coaming and adding a doubler plate to the deckhouse side adjacent to the opening, as discussed in the main text of this report. The additional coaming piece was welded completely around the existing coaming at both inboard and outboard edges. In addition to the previously mentioned modifications, a closure plate was used at Frame 33 port access hole in the deckhouse. The gages originally placed on the coaming were repositioned when the closure plate was installed. The gages formed a rosette near the upper forward corner of the opening. The remaining gage was placed at the lower forward corner on the doubler plate (a strain reading of 560 $\mu\epsilon$ was measured at 80% load). Also, fashion plates were added to the structure forward of Bulkhead 33.

Figure C.45 is a plot of the strain gradients (due to 80% BM) near the intersection of the port deckhouse corner at Bulkhead 92 and the main deck.

APPENDIX D

CALCULATED LOADS, MEASURED LOADS AND DEFLECTIONS, AND BENDING MOMENT PLOTS

This appendix contains, in tabular form, summaries of (1) the calculated loads which were to be applied to the ASEM, (2) the loads as recorded during the four tests chosen for data analysis, (3) moment plots derived from the recorded loads of the four tests, and (4) measured deflections which were recorded during the four tests.

The vertical loads are given in Table D.1. Both vertical hog and sag loads at each load increment are given. Note the hog or sag STILLWATER + ZERO STRESS values are at the same offset from ZERO STRESS. Also, for example, at 40 keel, even though the load at 80% was 11,090 lb in the sag condition and was -54,906 lb in the hog condition, the change (Δ) in load from zero + stillwater is equal (32,998 lb). The 90 or 100% loads are not included since the ASEM was not loaded to these magnitudes during the static tests. Also note that the rows associated with starboard LOAD CELL(s) are blank because no loads were applied during the vertical-loads-only tests.

The lateral loads are given in Table D.2. Both lateral hog and sag loads at each increment are given. The sag and hog load values at each load increment are equivalent in magnitude and opposite in sign. A lateral sag and hog condition is defined such that a hydraulic actuator/load cell arrangement will produce the same sign on the "readout" as would a vertical hog or sag condition (see Figure D.1). The rows associated with vertical load cells are left blank after the zero and stillwater loads are given. When lateral loads only were applied to the model, it was loaded vertically until the stillwater condition was reached and then lateral loads were applied.

Table D.3 summarizes the calculated loads to be applied to the model for the combined vertical and lateral loading test with a 60° phase shift. Loads are applied in a sinusoidal fashion (necessary for the cyclic tests), thus allowing the phase shift. The zero, stillwater, and vertical incremental loads are the same as the

vertical loading test but the lateral loads are derived from the equation $P_2 = P_{\max}/2 \sin (\omega t - 60^\circ)$. That means, when a vertical load is applied at a particular load frame and load level (10%, 20%, etc.), a corresponding lateral load is applied whose magnitude is determined from the above relation.

Table D.4 is a summary of the loads for the combined vertical and lateral loading test with a 240° phase shift. The explanation of this table is similar to that of Table D.3. Basically, the maximum lateral loads do not occur at the same time as the maximum vertical loads.

Tables D.5, D.6, D.7, and D.8 are tabular summaries of the loads which were monitored and recorded during the vertical test of 9/22/77, the lateral test of 10/28/77, the 60° combined loading test of 10/14/77, and the 240° combined loading test of 10/26/77, respectively. The UNLOCK load readings are obtained with the hydraulic system depressurized. Except for fixed support loads, these values will nominally be low. The system is then pressurized; next, ZERO and/or ZERO TEST conditions are read. The lateral loads should have been close to zero in magnitude; if not, they were adjusted accordingly and then recorded. Loads were then applied to produce a stillwater BM in the model. Up to this point, the loads for Tables D.5 through D.8 were similar in magnitude. However, the remainder of the loading conditions of the four tests were different. Table D.5 shows the loads read on all channels during the vertical-only-loading test. The lateral loads were nominally

near zero, and only the vertical readings showed significant changes. Table D.6 shows the loads read on all channels during the lateral-only-loading test. The vertical readings were nominally near the stillwater readings throughout the test, and the lateral readings indicated the load increments associated with load levels. There are a total of 30 load conditions, not including the stillwater load condition.

Tables D.7 and D.8 are probably the most significant in that the loads shown here are the same as those during the cyclic tests. The load values recorded in the lateral offset column require a brief explanation. The vertical loads are similar to loads of the vertical test, and the lateral test stillwater loads. However, the lateral loads are now representative of the phase shift discussed earlier. During the test, as the model was loaded, any load magnitude adjustment (if required) was done at that time.

Figures D.2 through D.9 are ASEM moment plots derived from the loads applied to the model during the associated tests. The magnitude of the maximum moment of the lateral-loads-only test (Figures D.3 and D.4) is one-half that of the vertical-loads-only test (Figure D.1) (4.3×10^6 ft-lb versus 2.1×10^6 ft-lb). In general, the applied BM were very close to the calculated bending moments as seen in Figure D.1.

Tables D.9 through D.12 are compilations of the absolute deflections as measured during Tests 1 through 4, respectively. The deflection plots in Figures 11 through 14 are deflections relative to stillwater. During Test 1, only vertical loads were applied, thus deflection readings of the starboard linear potentiometers showed little or no change at each load increment. During Test 2, after the stillwater loads were applied to the model, only lateral loads were subsequently applied, thus deflection readings of the keel linear potentiometers showed little or no change at each load increment. The deflections in Tables D.11 and D.12 were continuously changing as both lateral and vertical loads were applied to the model. Any deflection position, other than at Bulkheads 24 and 86, which showed little or no change in displacement during these two tests, was an indication that the instrumentation was probably malfunctioning.

APPENDIX E

STRAIN GAGE SPECIFICATIONS AND LOCATION NOMENCLATURE

A brief summary of the specifications of the strain gages and the lead wires used to obtain the strain data follows. Almost all gages were either Micro-Measurements single arm gages or rosettes (0° - 45° - 90°) type CEA-13-250LW-120 or CEA-13-250UR-120, respectively. These are general purpose constantan strain gages with a fully encapsulated gird having exposed solder tabs. The manufacturer recommends that they be used on aluminum material in a temperature range of -100°F to 400°F (test temperatures were well within this range). The active gage length for them is 0.25 in. with a gage resistance of 120 ohms. The nominal gage factor (G.F.) was 2 to 2.1%. The cement used for bonding them to the model was M-M Certified M-Bond 200 and waterproofing was also applied. At the completion of static and cyclic testing, the majority of the original gages were still functioning properly, approximately 5 years after they were installed.

The lead wires which ran from the strain gages on the model to completion panels below it were either Belden 8919, Style 1015 600V- 105°C lead wire, or Military Specification type 7003 lead wire. Both are 10 strand AWG 20 gage wire with insulation thicknesses of 3/32 in. O.D. for Belden and 2/32 in. for type 7003. The lead wire length ranged from 50 to 150 ft, depending on where the gage was located on the model. Gages internal to the hull generally required longer lead wires than exterior gages.

An alphanumeric numbering system for the strain gages was developed to locate them on the ASEM and to facilitate data analysis. The following is an explanation of the strain gage location nomenclature used in the tables of analyzed static test data in Appendix B.

First Character

B8COMMP

Gage is on a bulkhead

Generalized ship section where gage is located

"B" - Bulkhead

"H" - Hull

"F" - Platform Deck

"M" - Main Deck

"T" - 02 Deck

First character

Generalized ship section where gage is located

" ϕ " or "Z" - 01 Deck

"W" - Deckhouse Wall

"A" - Access Hole (Gage nomenclature different, see additional example for explanation)

Second Character

Specific frame or bulkhead location (may be 3 digit character)

B8COMMP

Gage is on Bulkhead 8

Third Character

Indicates gage location relative to port or starboard side of ship:

B8COMMP

On Bulkhead 8

At Centerline

"S" - Starboard

"P" - Port

"C" - Centerline plane of ship

Fourth Character

B8COHHRH

Gage is on Bulkhead 8 and it is located zero stiffeners P or S from Centerline

B8S2MFP

Gage is 2 stiffeners starboard of the Centerline on Bulkhead 8

Specific location of gage relative to Centerline of ship (usually refers to the number of stiffeners the gage is Port or Starboard off the Centerline). If the gage is located between two stiffeners the character is a decimal number. The number to the right of the decimal is the percent distance the gage is between the two stiffeners and the number to the left of the decimal is the number of the inboard most stiffener. If the strain gage is on a bulkhead, deck or hull, then the bulkhead, deck or hull stiffeners, respectively, are used as reference numbers.

Fourth Character

B8S2.5MFP

Gage is midway between 2nd and 3rd stiffener, starboard of the Centerline on Bulkhead 8

Fifth and Sixth Character

B8S2MFP

Gage is located on Bulkhead 8; 2 stiffeners starboard of Centerline and between the Main Deck (M) and Platform Deck (F)

Combination of two characters (see First Character for listing) gives approximate vertical location of gage. If the gage is located on a deck, these characters are omitted. If fifth and sixth characters are "NA", gage is near the N.A. of ASEM.

Seventh Character

(If not a Rosette)

B8S2MFP

Gage is on the nonstiffened or plate side of Bulkhead 8

Indicates whether the gage is on plate or stiffener. If the gage is on the plate, it may be on the stiffened or the nonstiffened side of the panel. If the fourth character is a decimal number, then it is positioned between two stiffeners, usually on the stiffened side of the structure

"P" - Plate

"S" or "W" - Stiffener (specifically the Web)

Seventh Character

(If a Rosette)

B8P5FFRD

Gage is one arm of a rosette

Indicates the channel is one of three arms of a rosette.

Eighth Character

(If a Rosette)

B8P5FFRD

Diagonal arm of a rosette on
Bulkhead 8 near the Platform
Deck

Indicates the direction of rosette arms:

"H" - If plane of the rosette is vertical, arm
is horizontal

"L" - Arm is longitudinal

"D" - Arm is 45° arm relative to "L" or "V"

"V" - Arm is vertical

A slightly different system is devised for describing the location of gages
near access holes:

First Character

Indicates access hole, "A"

APMM36C1S

Gage is near or on an
access hole

Second Character

Gage location relative to port or starboard side
of ship,

APMM36C1S

Access hole on port side
of ship

"S" - Starboard

"P" - Port

"C" - Centerline plane of ship

Third and Fourth

Character

Defines level the access hole is on;

APMM36C1S

Port access hole is on
the main deck

"MM" - On Main Deck level

"Mφ" - Between Main Deck and 01 deck level,
on deckhouse side

"φφ" - on 01 Deck level

"TT" or "ZZ" - on 02 Deck level

"φT" or "φZ" - Between 01 and 02 Deck level

Fifth Character

APMM36C1S

Port access hole is at
Frame 36 on the Main Deck

Specific frame or bulkhead location (may be a
3-digit character);

Sixth Character

APMM36C1S

Gage is on the coaming of
the port access hole at
Frame 36 on the Main Deck

Indicates if the gage is on the coaming, "C", of
the access hole or the plate, "P", adjacent to the
access hole or if a rosette, "R", is on the plate
adjacent to the access hole;

Seventh Character

APMM36C1S

Port Main Deck access hole
at Frame 36, the gage is
the first of a series of
gages on the coaming

Gage number for a sequence of gages

- a) For coaming and plate gage: this number
increases going clockwise (looking down) with
#3 gage at end of corner radius (1, 2, 3, 4
or 5) for square opening.
- b) For rosette: orientation of (V, L, D or H)
rosette arm
- c) For oval (not square) holes: this gage number
is omitted (see Eighth Character for oval
holes).

Eighth Character

APMM36C1PA

Port Main Deck access hole
at Frame 36, the gage is the
first of a series on the port
aft corner of the coaming
(port relative to centerline
of coaming)

Locates corner of access hole gage is located on.

For coaming gage:

- a) For square access holes, the corner is denoted
by 2 letters
"P" - Port or "S" - Starboard
"F" - Forward or "A" - Aft
- b) For oval holes, counterclockwise angle is
degrees to gage with 3 o'clock being 0°
(looking inboard)

Eighth Character

APMM36P1PFO.5

Port main deck access hole at Frame 36, the gage is near the port forward corner of the port section of coaming and lines up with the first of a series of gages on the coaming. It is 0.5 in. from the coaming.

Plate gage:

The coaming gage that lines up with the plate gage is identified and then the distance from the coaming is identified as the 11th, 12th and 13th character.

Rosettes:

The corner of the hole is identified

"P" - Port or "S" - Starboard and

"F" - Forward or "A" - Aft

"φ" - 01 Level (top of hole)

"M" - Main Deck Level (bottom of hole)

DTNSRDC ISSUES THREE TYPES OF REPORTS

1. DTNSRDC REPORTS, A FORMAL SERIES, CONTAIN INFORMATION OF PERMANENT TECHNICAL VALUE. THEY CARRY A CONSECUTIVE NUMERICAL IDENTIFICATION REGARDLESS OF THEIR CLASSIFICATION OR THE ORIGINATING DEPARTMENT.

2. DEPARTMENTAL REPORTS, A SEMIFORMAL SERIES, CONTAIN INFORMATION OF A PRELIMINARY, TEMPORARY, OR PROPRIETARY NATURE OR OF LIMITED INTEREST OR SIGNIFICANCE. THEY CARRY A DEPARTMENTAL ALPHANUMERICAL IDENTIFICATION.

3. TECHNICAL MEMORANDA, AN INFORMAL SERIES, CONTAIN TECHNICAL DOCUMENTATION OF LIMITED USE AND INTEREST. THEY ARE PRIMARILY WORKING PAPERS INTENDED FOR INTERNAL USE. THEY CARRY AN IDENTIFYING NUMBER WHICH INDICATES THEIR TYPE AND THE NUMERICAL CODE OF THE ORIGINATING DEPARTMENT. ANY DISTRIBUTION OUTSIDE DTNSRDC MUST BE APPROVED BY THE HEAD OF THE ORIGINATING DEPARTMENT ON A CASE-BY-CASE BASIS.
