Cost estimating relationships (U.S. fleet/USSR fleet)

20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

Cost estimating relationships based on the observed (reported) cost and weight (full load displacement) of U.S. Navy ships are derived for the purpose of applying these cost estimating relationships to ships in the fleets of both the U.S. and USSR. This application results in broad, general comparisons that, in the aggregate, provide useful trend comparisons. These cost estimating relationships produce varying results on a class basis, but within each group or category of ships the class overestimates tend to be offset by class underestimates to yield a relatively small category error. PREFACE

This paper was prepared by the Institute for Defense Analyses (IDA) for the Special Assistant for Assessment, Office of the Under Secretary of Defense for Research and Engineering, under Contract MDA 903 79 C 0018. The study was under the cognizance of Dr. Paul J. Berenson.

This paper is one of a continuing series of studies at IDA on various comparisons of U.S. and USSR military RDT&E and procurement programs. One aspect of these comparisons involves determination of investment balance. Because information about Soviet weapon costs is limited, one way to compare the U.S./USSR balance is to base estimates on other data that are observable or can be determined by other means.

Cost estimating relationships based on the observed (reported) cost and weight (full load displacement) of U.S. Navy ships are derived for the purpose of applying these cost estimating relationships to ships in the fleets of both the U.S. and USSR. This application results in broad, general comparisons that, in the aggregate, provide useful trend comparisons. These cost estimating relationships produce varying results on a class basis, but within each group or category of ships the class overestimates tend to be offset by class underestimates to yield a relatively small category error.

This paper updates major portions of IDA Paper P-1530, *Simple Relationships for Estimating Procurement Cost of U.S. Navy Ship Categories*, dated March 1982.

SUMMARY

An initial cut at estimating the procurement cost of categories of naval ships is to use cost-weight relationships. These relationships are useful for estimating the procurement cost of naval ships on an aggregate basis rather than forecasting the cost of individual ships or classes of ships. The cost estimating relationships (CERs) in this paper were developed to compare the procurement cost of U.S. and Soviet naval ships. The estimates of Soviet ship costs are simply what cost the U.S. would incur if ships of the same displacement as Soviet ships were procured in the U.S.

In developing the cost estimating relationships, the following procedures and assumptions were applied:

1. Only costs for ships already delivered were used except for the Aegis cruisers and Ohio class SSBNs.
2. All cost data came from the U.S. Naval Sea Systems Command.
3. Costs were converted to constant Fiscal Year 1983 dollars.
4. Costs for ship conversions were excluded.
5. A least-squares method was used to determine the regression equation.
6. CERs which intersected the displacement axis (abscissa) were disallowed and the CER was forced to go through the origin (i.e., a negative cost estimate for a positive displacement was not allowed).
7. A constant incremental cost over a specified range of ship displacement was assumed for the procurement cost of a nuclear powered ship relative to that of a non-nuclear powered ship of the same category.

The cost estimating relationships derived for each category of ships are presented in Table S-1. Where the least error CER (least average ship class absolute error) is a form other than linear, the linear CER also is displayed. In addition, Table S-1 displays the total observed cost, the total estimated cost, and the percent difference between the observed and estimated costs for each ship class and category. The estimate error for a category of ships is generally less than the average ship class absolute error for classes comprising the same category due to cancellation effects. For example, using the least error CER the error for the Aircraft and Helicopter Carriers category is 1.3 percent, whereas the individual ship class errors range from 2.2 to 11.7 percent, for an average ship class absolute error of 5.9 percent.

On balance, these simple CERs can provide an accurate estimate of the aggregate procurement cost at the force or fleet level. The estimated aggregate procurement cost of the 60 classes of ships comprising the 11 ship categories using these CERs is within one percent of the observed aggregate procurement cost. These CERs should not be used to predict the cost of individual ships or new classes of ships.

**Least error CER is defined as the CER that has the least average ship class absolute error.

***Linear CER is displayed where the least error CER is another form.

[a]CGN-9 was not included in deriving the CER, thus the CER is not applicable.

Table S-1. (Continued)

Class	Lead Ship Hull No.	No. of Ships Costed	IOC	Full Load Displace-ment-LT*	Lead Ship Cost	Observed Ave. Cost of Ships by Class	Estimated Cost	Percent Difference	CER
Destroyer and Submarine Tender									
AD	37	2	1967	20,500	354.5	325.2			
	41	4	1980	20,500	391.5[k]	407.6			
AS	31	2	1962	19,819	351.4[l]	355.4	Data was too clustered to produce a reasonable CER.		
	33	2	1964	21,000	408.3	359.8			
	36	2	1970	23,493	324.2	286.1			
	39	3	1979	22,646	450.7	425.2			

[*] LT = Long Tons.

[a] Low lead ship cost is because of the four ships in this class, the first and third ships were built at Newport News and the second and fourth ships were built at the New York NSY. These latter ships were more costly than the lead ship built at Newport News.

[b] Data includes the Thresher (SSN-593) which was lost during sea trials. This class was omitted from the derivation of the CER.

[c] The lead ship was built by Electric Boat, however, the first four follow-on submarines were built by four different shipyards, (two NSYs and two PSYs) all at a higher cost than the lead ship.

[d] The first eight ships in this class were built by the same shipyard. Follow ships three and four were about 80 percent more costly than the lead ship. The remainder of the ships were built at about 56 to 74 percent of lead ship cost by two builders.

[e] The DDG-37 class was originally classified as the DLG-6 class.

[f] Although the LST-1171 is the lowest hull number of this class, the class is named for the Suffolk County (LST-1173) which is designated the lead ship of the class.

[g] The first three ships of this class were authorized and funded in the same year. The cost data available did not identify costs by hull number; therefore, the cost for the lead ship cannot be determined.

[h] The LCC-19 was built by the Philadelphia NSY and the follow ship by Newport News at about 55 percent of the lead ship cost.

[i] Ships of the AE-26 class were authorized and funded at a rate of two per year, both built by the same builder. It appears that the cost of the first two ships were about equally divided; therefore, a typical lead/follow ship cost relationship does not exist.

[j] Same situation as for the AE-26 class.

[k] Two of the three follow ships cost more to build than the lead ship.

[l] The two ships of this class were built by two shipyards with the follow ship more costly than the lead ship.

INTRODUCTION

There are many varieties of comparisons of U.S. and Soviet naval activities. Obviously, an overall comparison of capabilities is desired but it is not feasible. Instead a set of comparisons must be substituted. One is the aggregate comparison of the annual cost of procurement of ships in the U.S. and Soviet fleets. Another estimates the asset value of the ships in each active fleet. This paper provides a way of developing both these estimates. Another comparison is of the numbers of ships and their displacements. However, both quantitative and qualitative dimensions of the two fleets are reflected in the procurement costs. To permit the comparisons in comprehensible terms, U.S. currency is used for both the U.S. and USSR. Thereby, one can measure the overall size and direction of both U.S. and Soviet naval programs in resource terms. To remove most of the effects of inflation; costs are expressed in constant dollars.

The estimates of procurement costs of Soviet ships are based on algorithms developed from U.S. historical ship procurement costs. Cost estimates of Soviet ship procurement do not measure the manufacturing efficiencies in Soviet shipyards; they are estimates of what it would cost to produce Soviet ships in U.S. shipyards using U.S. production technology. These dollar costs are not likely to represent the actual Soviet ship procurement costs nor the burden of such procurement on the Soviet economy.

This paper records the derivation of simple ship cost estimating relationships (CERs) based on ship displacement. A similar set of CERs was published in Table S-1 of IDA Paper P-1530

[Reference 1]. The categories (groups) of ships used to derive the CERs in P-1530 and in this paper are essentially the same except for minor variations. The changes in the derivation of ship CERs from P-1530 are addressed in the following paragraphs.

There are three major variations. Reference 1 presented only a linear relationship between ship full load displacement and procurement cost for each set of categories. Here two additional mathematical forms of equations to describe the ship displacement/procurement cost relationship are also tested. When either of these equations provided a better fit (the least average ship class absolute error) this is presented for each ship category. The linear relationship is also displayed. A least squares technique was used in all cases to fit equations to the data.

An attempt was made to include the year of IOC as a time-dependent variable. The linear multiple regression equation that resulted from converting the logarithmic equation to a power form is given in paragraph D2 of the Methodology Section. The time-dependent variable (the last two digits of the year of the ship class IOC minus 81)[1] was included to account for the effect of cost increase from one generation or class of ships to the next. This cost increase is commonly believed to result from the incorporation of progressively advancing and more costly technology. However, the linear multiple regression analysis yielded spurious results, and the equations are not included.

The second change is that the costs in P-1530 are expressed in FY 1979 dollars; whereas, the costs in this paper are in FY 1983 dollars. TOA deflators published by OSD dated 2 February 1982 were used to convert "then-year" dollars to FY 1983 dollars.

[1]The year 1981 was chosen as a reference year for the time-dependent variable.

Third, there is a difference in the composition of the ships comprising each group of ships. The lead ship has been included in the data upon which the CER is derived in this paper, but it was not included in the CERs derived in P-1530, except in a few instances. In most cases only costs for ships already delivered were used. Exceptions are ships of the SSBN-726 and CG-47 classes which are still being built. For these classes cost estimates were used. Although all the ships used have been authorized and funds appropriated for construction, these ships still have the potential for cost increases due to inflation, claims, cost growth, outfitting and post delivery costs.

METHODOLOGY

A. SELECTION OF CER CATEGORIES

Classes of U.S. Navy ships were aggregated into groups (categories) according to characteristics, functions, and missions to obtain a fit of mathematical curve forms to the data. Some ships did not fit well in their logical category based on these criteria; thus other criteria of hull design, machinery arrangement, and similarity of construction were used to categorize these ships. Examples are the amphibious assault ships (LHAs and LPHs), which are grouped with aircraft carriers vice amphibious ships, and amphibious cargo ships (LKAs), which are included with underway replenishment ships vice amphibious ships.

Nuclear powered ships were separated from non-nuclear powered ships of the same type and escort ships (cruisers, destroyers, and frigates) equipped with missiles were separated from non-missile-equipped escorts. The AEGIS cruisers were placed in a category by themselves because of their uniqueness. The number of ships in a class varied from one to 46. Each class represents one data point. In this paper 60 ship classes were organized into 12 CER categories.

1. Aircraft and helicopter carriers (CV, LHA, LPH)
2. Nuclear powered aircraft carriers (CVN)
3. Nuclear powered attack submarines (SSN)
4. Diesel powered submarines (SS)
5. Fleet ballistic missile submarines (SSBN)
6. Destroyers, frigates, and patrol combatants (DD, FF, PG)
7. Guided missile cruisers, destroyers, and frigates (CG, DDG, FFG).

8. Aegis cruisers (CG)
9. Guided missile cruisers (nuclear powered) (CGN)
10. Amphibious ships (LST, LSD, LPD, LCC)
11. Underway replenishment ships (AE, AF, AFS, AO, AOE, AOR, LKA[1])
12. Destroyer and submarine tenders (AD, AS)

These 12 categories are essentially the same as those in P-1530 except that the categories of mine warfare ships, tugs and salvage vessels, and single unit classes were omitted in this paper, and fleet ballistic missile submarines were added.

B. DATA SOURCES AND THEIR USE

The cost data were extracted from four Naval Sea Systems Command (NAVSEA) sources. For the period fiscal years 1952-1969, a report entitled Estimated Cost to Build or Convert Naval Ships [Reference 2] was used. This report provided by program year a total end cost for each ship by hull number including outfitting and post delivery costs. This end cost does not identify the year funds were appropriated, and it was assumed to be the program year. A single deflator for the program year was used to convert to FY 1983 dollars. Using a single deflator may overstate the cost of a ship in FY 1983 dollars, since some costs associated with construction between fiscal years 1952 and 1970 were appropriated in years subsequent to the program year. This possible overstatement of cost is believed to be small, because of the low rate of inflation during the early part of this period of time.

For the period FY 1969-1981 cost data were obtained from NAVSEA report Shipbuilding and Conversion, Navy, Shipbuilding Status Report as of December 1981 [Reference 3]. This report

[1]LKA ships included here because of the similarity in construction to AE and AF ships.

incorporates changes in NAVSEA accounting procedures. It displays cost information by program year for each ship by hull number. The cost for each ship is presented by major cost category code as defined in NAVSEA Instruction 7302.1 dated 6 October 1977. A major difference in the costs displayed in these two NAVSEA reports is in the accounting of outfitting and post delivery costs and what is included in the "Total End Cost." In reference 2 both outfitting and post delivery costs are included in "Total End Cost." In reference 3 neither outfitting nor post delivery costs are included in "Total End Cost," but, they are added to "Total End Cost" to produce a new cost term called "Grand Total Hull."[1] Both cost terms include all the elements of cost incurred to build a ship.

In reference 3 outfitting and post delivery costs are displayed for each year in which these funds were appropriated. Other cost category items funded in a fiscal year other than the year in which the ship was authorized and funds appropriated for construction are advance procurement, cost growth, escalation, and claims. To reflect properly the total cost of a ship in FY 1983 dollars that had funds in any of these cost categories, the deflator for the year in which the item was appropriated was applied. Before this last step was possible, the amount funded by year for each cost category was identified. Reference 3 provides this level of detail for outfitting and post delivery, but not for advance procurement, cost growth, escalation, and claims.

Identification of the amount of funds appropriated by fiscal year for each of these categories was accomplished through extracting data from NAVSEA status sheets entitled <u>Shipbuilding and Conversion, Navy, Program Years 1962-1982</u> [Reference 4] and

---

[1] Beginning in the mid 1970s outfitting and post delivery costs have been budgeted as a separate line item in the Shipbuilding and Conversion, Navy appropriation. The costs for outfitting and post delivery frequently appear in the program in more than one fiscal year.

Derivation of Cost Growth/Escalation, Etc., [Reference 5]. For example, in reference 4 the amount of advance procurement is displayed by fiscal year for a ship or a block of ships where several ships of the same class were funded in the same fiscal year. In this latter case, reference 3 was used to identify the amount of advance procurement allocated to each ship.

For the categories cost growth, escalation, and claims that were funded during FY 1972-1983, the amount funded is displayed in reference 4 as a single entry. However, reference 5 identifies the amount by fiscal year for each of these cost categories except for the period FY 1972-1975. The amount funded for these three cost categories for these four fiscal years is displayed as a single number. In order to estimate the cost of cost growth, escalation, and claims for these four years in FY 1983 dollars, an average deflator (43.5992) was derived from appropriate SCN OSD indices.

To summarize the use of references 3, 4 and 5 and to demonstrate the calculation of FY 1983 dollars, the following example using the USS Eisenhower (CVN-69) is displayed.

Ships are funded under the full funding concept whereby the Navy budgets and the Congress appropriates funds to fully finance the construction of a ship in the year of authorization, except for advance procurement, claims, outfitting, and post delivery. In the USS Eisenhower example the program year line represents the amount estimated to fully fund the ship in FY 1970 dollars. Advance procurement was provided in each of the two previous years. During the period FY 1972-1979 almost $221 million in then-year dollars were required to pay for unbudgeted escalation and cost growth, and claims. To accurately translate then-year dollars to FY 1983 dollars the appropriate deflator corresponding to each fiscal year in which funds were appropriated must be applied. This application of a number of deflators is especially important for ships authorized and funded from the late 1960s to the present time due to the inflationary effects of the economy.

Table 1. USS EISENHOWER (CVN-69) PROCUREMENT COSTS (Dollars in Thousands)

Cost Category	FY[a]	TOA Then Year $	Deflator	TOA FY 1983 $	Reference Source
Program Year Procurement[b]	70	388,361	28.8151	1,347,769	3,4
Advance Procurement	68	48,523	23.9695	202,436	4
	69	82,400	25.8534	318,720	4
Cost Growth/Escalation/Claims	72-75	182,195	43.5992	417,886	5
Cost Growth	76	13,954	54.6575	25,530	5
Claims/Escalation	77	11,349	61.7250	18,386	5
Claims	79	13,298	74.4161	17,870	5
Outfitting	76	4,676	54.6575	8,555	3
	7T	698	60.2517	1,158	3
	77	4,430	61.7250	7,177	3
	78	471	67.9456	693	3
Post Delivery	78	13,479	67.9456	19,838	3,4
Total		763,834		2,386,018	

[a]Fiscal year in which the funds were appropriated.

[b]This is the amount appropriated in the year the ship was authorized. The TOA amount in reference 4 is the same as the Total Net Procurement entry in reference 3.

C. NORMALIZATION OF THE DATA

The costs to procure ships were normalized to constant FY 1983 dollars. For an example of this process see Table 1. Other factors affecting cost that could have been normalized are lead ship costs, the number of ships built serially, and the differences in shipyards. These were not done for the following reasons.

Lead ship costs were included in the data to derive the CERs because the CERs are intended to estimate the cost of groups of Soviet and U.S. ships, which include both lead ships and follow ships. Had the purpose been to derive CERs to estimate the cost of the next U.S. ship of a specific class, the normalization for lead ship cost would have been appropriate.

IDA Paper P-1530 examined the effects of building ships serially and concluded that there is essentially no learning curve in most Navy ship construction (if the lead ship is not included). Figures 2 and 3 of P-1530 illustrate this conclusion. The lack of learning in ship construction allows a single point representing the average ship procurement cost to suffice in the CER derivation.

There may be variations in cost that can be attributed to differences in shipyards. These differences can result from geographic location, public versus private shipyards, and other more subtle factors. The most significant difference in cost has been between ships of the same class that were constructed in public and private shipyards. Large variations in cost were the exception rather than the rule. Navy ships have not been constructed in public shipyards since 1968, thus this difference is no longer applicable. One would reasonably expect to find similar differences among Soviet shipyards, thus normalization for shipyard differences was not considered appropriate.

Other factors influencing the cost of ships are ship program, method of contracting, and scheduling. No attempt is made to make adjustments for these factors.

D. COST ESTIMATING RELATIONSHIPS

1. Cost-Displacement Relationship

Three equations of curve fit forms were used to test the cost-displacement relationship for each of the 12 groups of ships. The three equations and their function forms that were used are:

(1) $C = A + BD$ Linear Function

(2) $C = Ae^{BD}$ Exponential Function

(3) $C = AD^{B}$ Power Function

Where:

C = Average ship procurement cost in millions of dollars

A = A constant

B = A constant

D = Ship full load displacement in thousands of long tons.

The method least squares was used to fit each equation to the data. On occasions when equation (1), the linear form, resulted in a negative value of A, it was disallowed as it implies that a ship of finite displacement could be built for zero cost. Whenever this condition happened a simpler linear equation ($C = BD$), which passes through the origin, was used. In this paper when either equations (2) or (3) yielded the least error it was also presented to describe the cost-displacement relationship.

2. Cost-Displacement IOC Relationships

As mentioned in the introduction, an IOC-dependent term was included to account for the cost increase from one generation of ships to the next. The data were transformed into logarithmic expressions of the variables and a linear multiple regression analysis performed. The linear multiple regression equation that results from converting the logarithmic equation to a power form is as follows:

$$C = AD^{B}T^{(IOC-81)}$$

Where:

C = Average ship procurement cost in millions of dollars

A = A constant
B = A constant
T = A constant

The value of the constant differs for each group of ships regressed.

D = Ship full load displacement in thousands of long tons

(IOC-81) = Last two digits of the ship class IOC minus 81, the reference year for the time-dependent term.

The results of this regression analysis yielded spurious results and are not displayed in this document.

RESULTS

Both the linear form of CER, and the form when the least error CER is not linear, are displayed in Table 2 along with other selected informational data. The differences (a) between observed and estimated costs for each ship class, and (b) between the total observed cost and the corresponding total CER estimated cost for each major grouping of ships, are also presented in Table 2. In all cases the two total costs for the major groupings are quite close, because the positive and negative differences of the estimated costs relative to the observed costs for each individual class of ship tend to cancel out within the major groupings. The results for each group of ships regressed are discussed in the following sections in the same order as they appear in Table 2.

A. AIRCRAFT AND HELICOPTER CARRIERS

In this category conventional carriers (CVs) are combined with the LHA and LPH amphibious assault ships. This combination was necessitated by the three classes of CVs (CV-59, 63, 67) having about the same full load displacement. The power form of cost-weight relationship best fits the data $\left(C = 12.3D^{1.122}\right)$. The category error was 1.3 percent and the average ship class absolute error was 5.9 percent. Figure 1 displays both the power form curve and the linear relationship. The linear equation produced a negative intercept, therefore a simpler linear equation which passes through the origin (C = 20.66D) was fitted. The category error using this equation was 3.7 percent and the average ship class absolute error was 8.5

*LT = Long Tons.

[a]Low lead ship cost is because of the four ships in this class, the first and third ships were built at Newport News and the second and fourth ships were built at the New York NSY. These latter ships were more costly than the lead ship built at Newport News.

[b]Data includes the Thresher (SSN-593) which was lost during sea trials. This class was omitted from the derivation of the CER.

[c]The lead ship was built by Electric Boat, however, the first four follow-on submarines were built by four different shipyards, (two NSYs and two PSYs) all at a higher cost than the lead ship.

[d]The first eight ships in this class were built by the same shipyard. Follow ships three and four were about 80 percent more costly than the lead ship. The remainder of the ships were built at about 56 to 74 percent of lead ship cost by two builders.

[e]The DDG-37 class was originally classified as the DLG-6 class.

[f]Although the LST-1171 is the lowest hull number of this class, the class is named for the Suffolk County (LST-1173) which is designated the lead ship of the class.

[g]The first three ships of this class were authorized and funded in the same year. The cost data available did not identify costs by hull number; therefore, the cost for the lead ship cannot be determined.

[h]The LCC-19 was built by the Philadelphia NSY and the follow ship by Newport News at about 55 percent of the lead ship cost.

[i]Ships of the AE-26 class were authorized and funded at a rate of two per year, both built by the same builder. It appears that the cost of the first two ships were about equally divided; therefore, a typical lead/follow ship cost relationship does not exist.

[j]Same situation as for the AE-26 class.

[k]Two of the three follow ships cost more to build than the lead ship.

[l]The two ships of this class were built by two shipyards with the follow ship more costly than the lead ship.

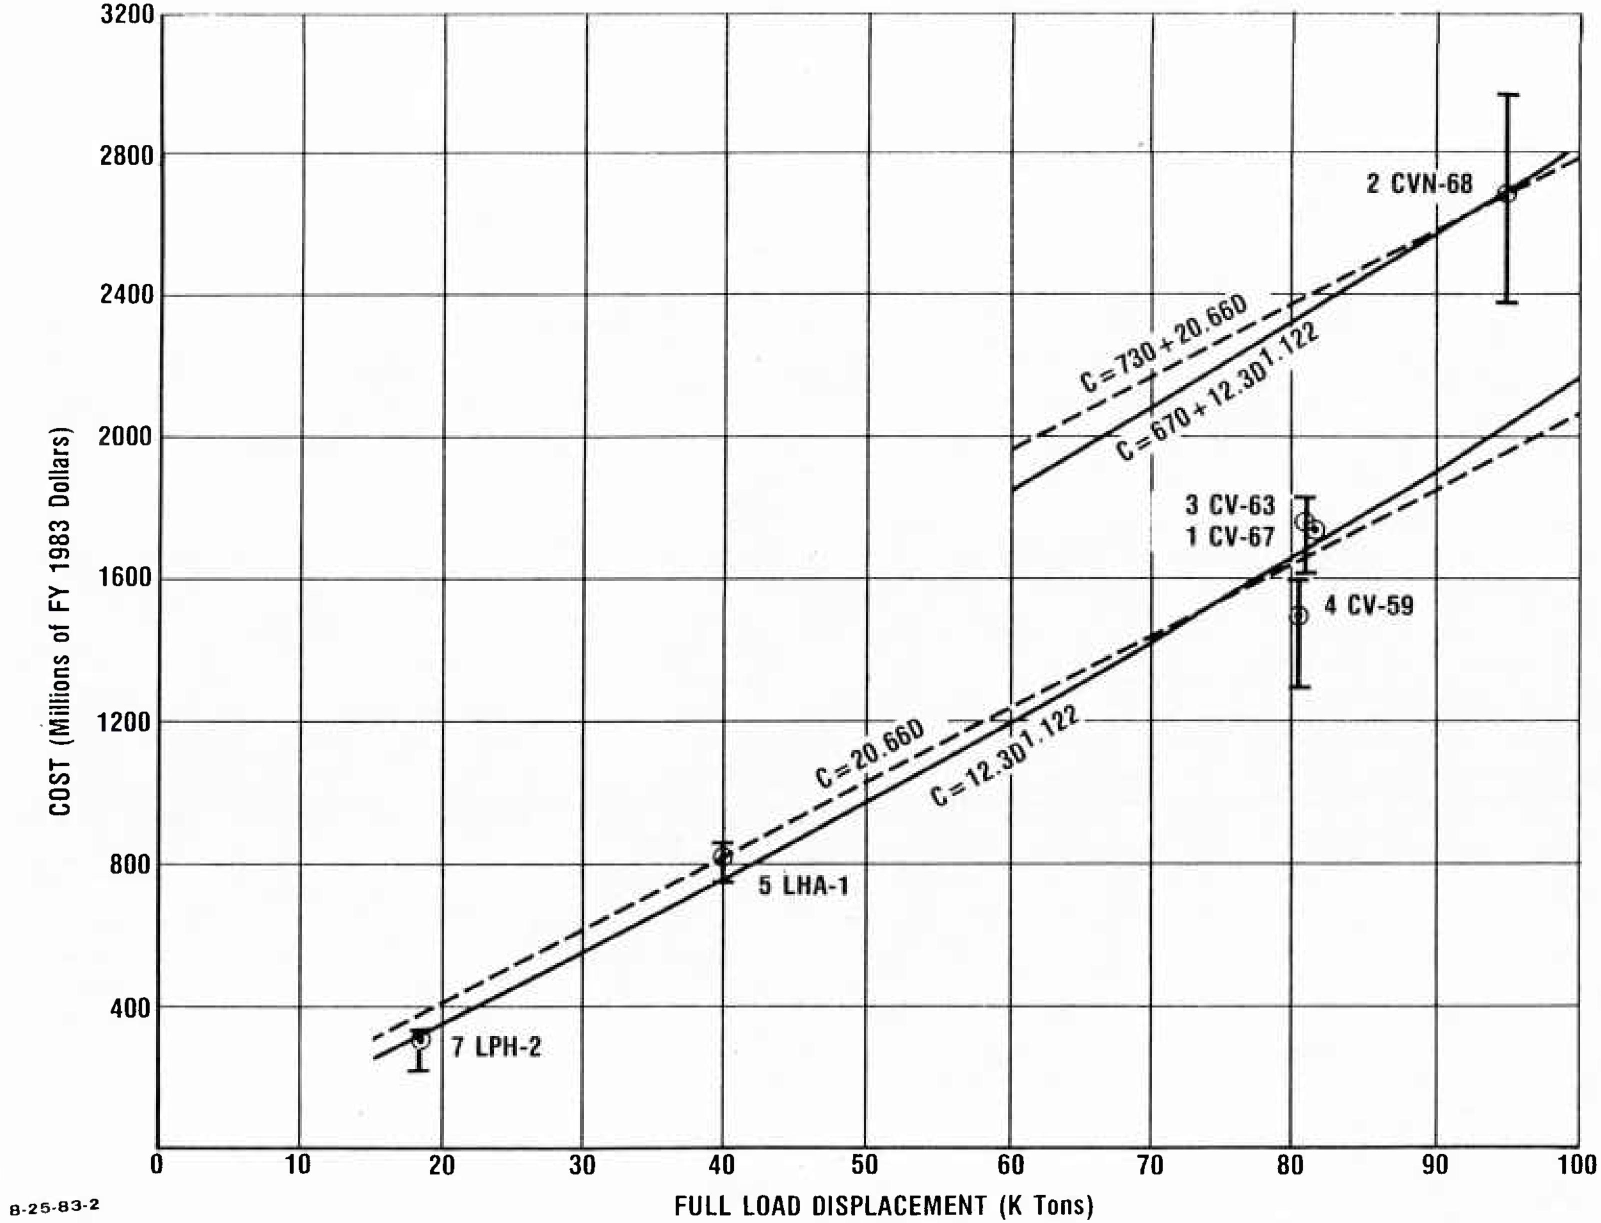

Figure 1. COST VERSUS WEIGHT CURVES FOR AIRCRAFT AND HELICOPTER CARRIER

percent. A comparison of the two curves described by these equations can be observed in Figures 2 and 3.

There are only two classes of U.S. nuclear powered aircraft carriers (CVN-65 and 68) with full load displacements that are proximate. The CVN-65 is a one-of-a-kind ship and the first CVN ever built. Thus using the CVN-65 cost as a data point is unwarranted. This leaves a single data point for the CVN-68 class from which to develop a CER. One alternative is to simply draw a line from the origin through the CVN-68 data point. This would imply that one could build small nuclear powered air capable ships for a small increase in cost over that of a conventional powered ship of the same size.

A recently completed IDA study[1] indicates that the increased cost for nuclear propulsion over conventional propulsion for U.S. aircraft carriers may be much closer to a constant. The cost of nuclear power in relation to ship weight is very likely some form of a step function; however, over some range of weight for a given type of ship it is probably close to a constant. The addition of nuclear power to any ship is a complex operation; therefore, an attempt to estimate the cost of nuclear power from one type of ship to another is likely to yield questionable results. IDA Draft Report R-265 identified seven comparisons of procurement cost ratios between nuclear and conventionally powered aircraft carriers displacing 80,000-90,000 tons. The ratios of the cost of nuclear power to conventional power ranged from 1.37 to 1.59 (an average of 1.46). Similar comparisons for carriers displacing about 60,000 tons yielded ratios ranging from 1.64 to 1.75. These data suggest that a constant incremental cost for nuclear power for aircraft carriers ranging from 60,000-90,000 tons is reasonable. This

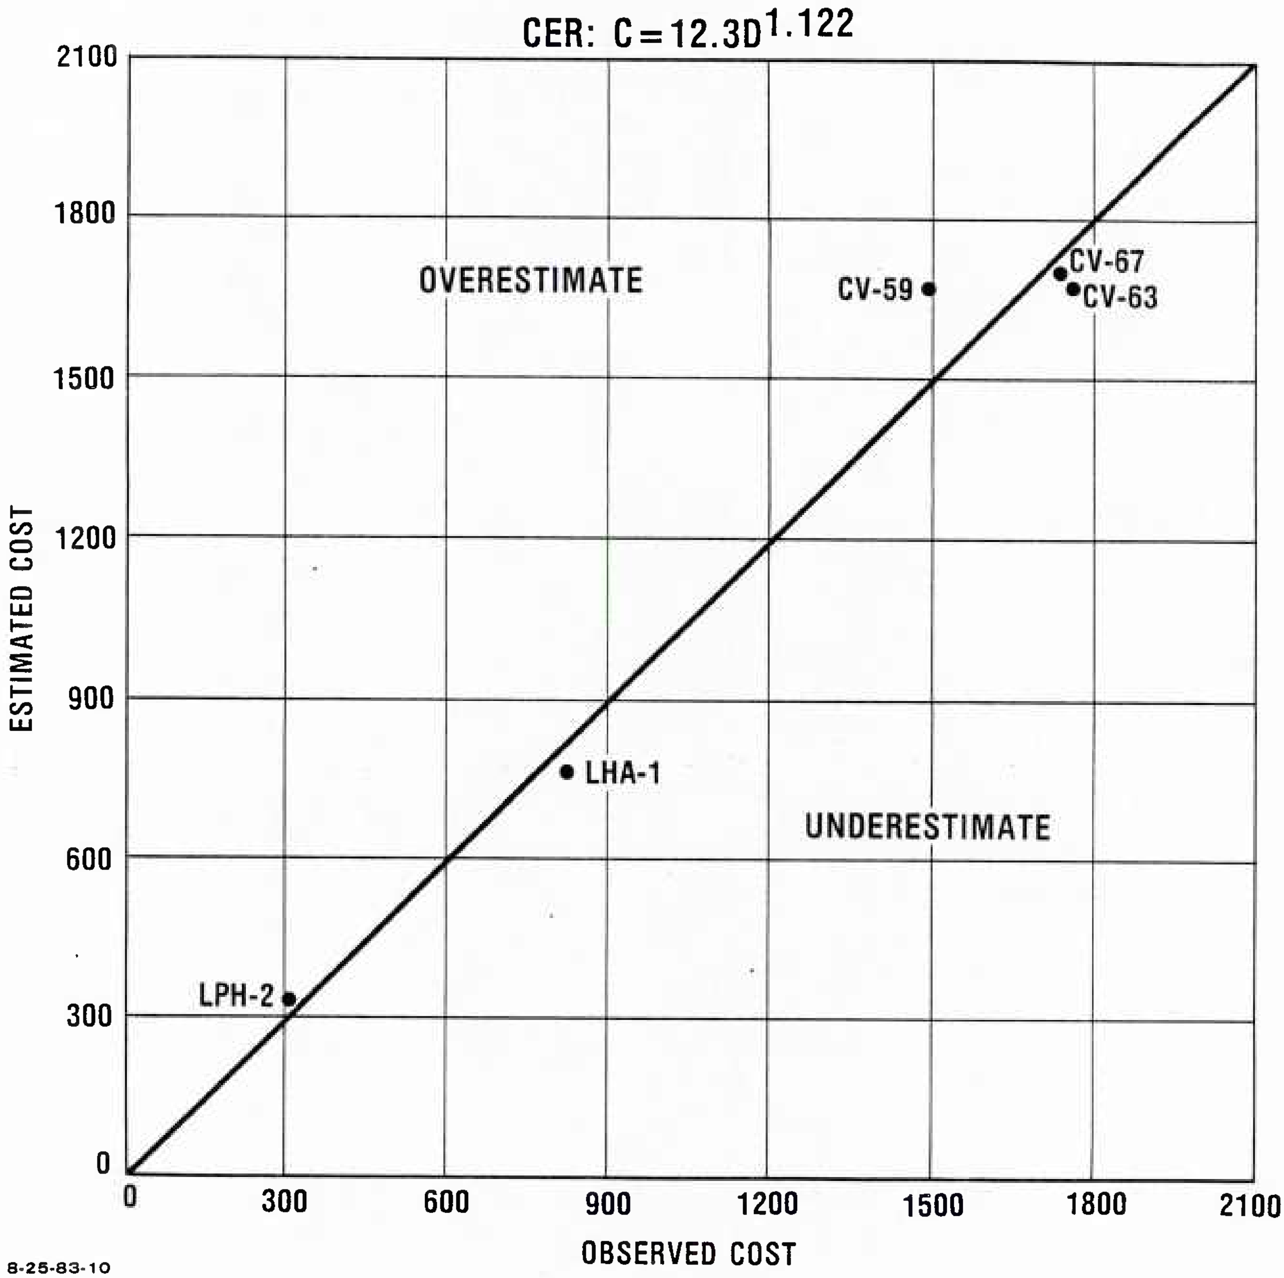

Figure 2. ESTIMATED COST OF AIRCRAFT AND HELICOPTER CARRIERS BASED ON WEIGHT VERSUS OBSERVED COST FOR SHIP PROCUREMENT USING A POWER FORM EQUATION

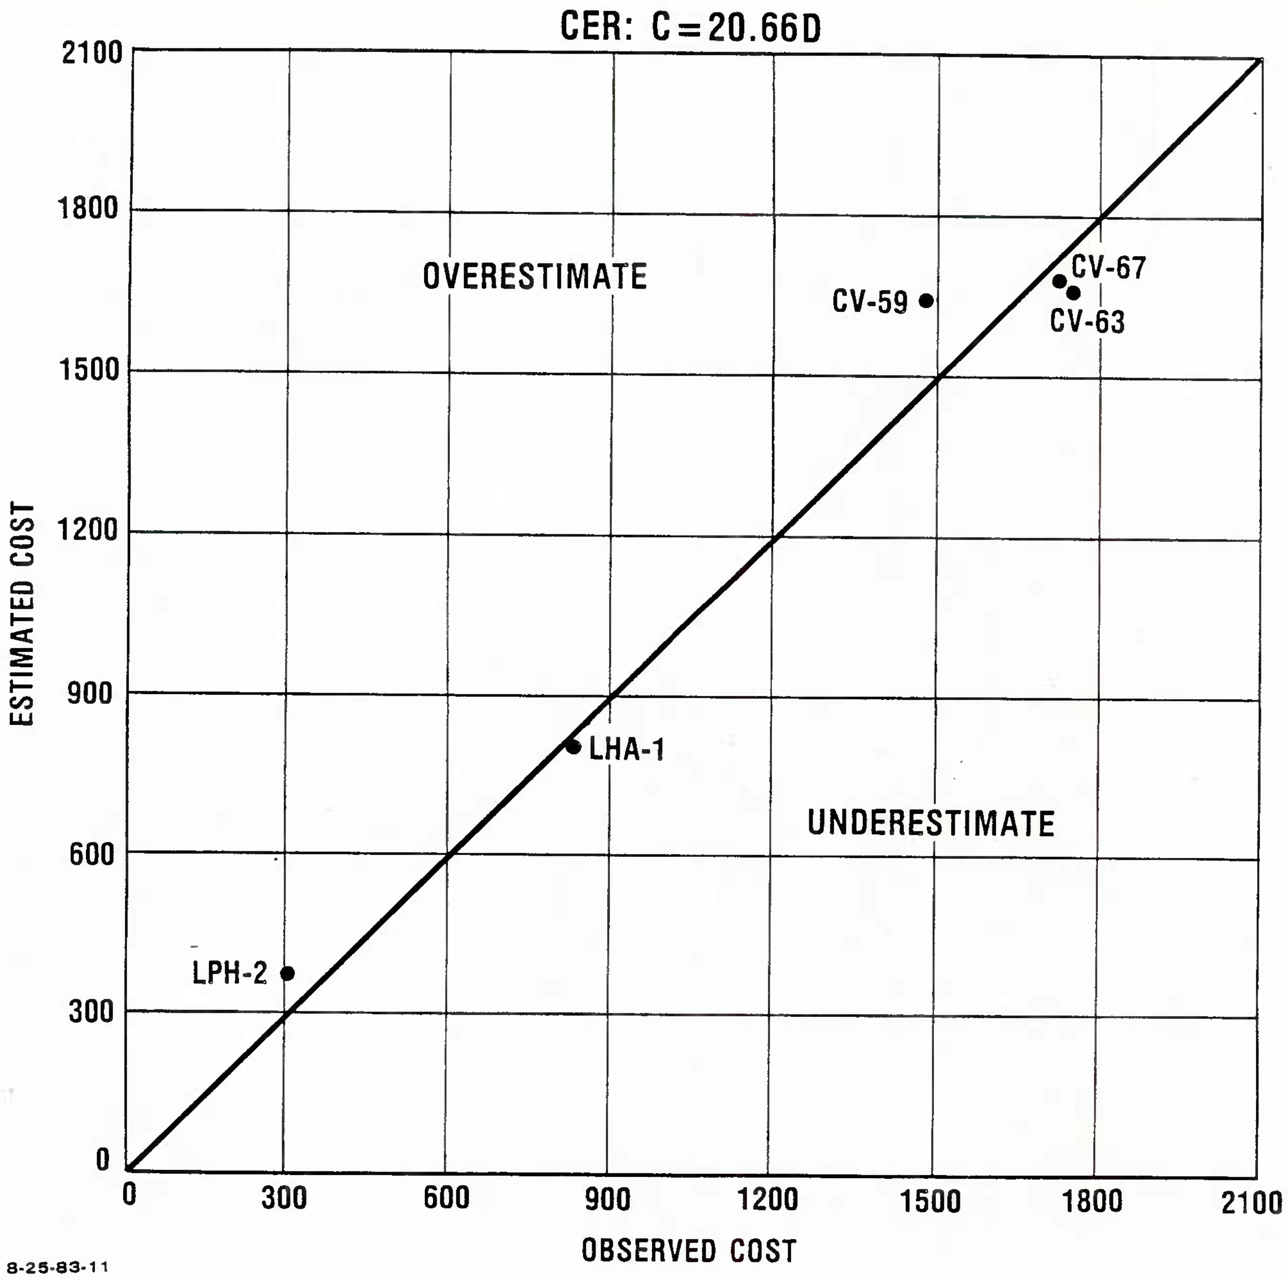

Figure 3. ESTIMATED COST OF AIRCRAFT AND HELICOPTER CARRIERS BASED ON WEIGHT VERSUS OBSERVED COST FOR SHIP PROCUREMENT USING A LINEAR EQUATION

incremental cost for nuclear power was estimated to be $670 million based on the difference between the cost of the CVN-68 class and the non-linear equation of Figure 1 and $730 million based on the linear equation. The non-linear equation that describes the CVN cost estimate curve is $C = 670 + 12.3D^{1.122}$ and the linear one is $C = 730 + 20.66D$.

The reader is cautioned in the case of these CERs. The CERs are based on LPH and LHA data at the smaller displacements and CV/CVN data for displacement values of about 80,000 tons and above. The curve could lead to an under estimation of the cost of building CVs having displacements in the range of 40-60,000 tons. Amphibious assault ships which can support helicopters of VSTOL aircraft, do not possess catapults, angle decks, and the extensive avionics shop and support facilities that would be required of a small CV capable of operating air superiority aircraft.

B. ATTACK SUBMARINES

This category is separated into nuclear powered (SSN) and conventional powered (SS) submarines. Five classes of SSNs have been authorized and funded since 1957. The latest class, the SSN-688 class, is still in the construction phase. Twelve of these SSNs have been delivered and their cost is used in the development of the SSN CER. The cost/displacement relationship for four classes of SSN is linear. One class, the SS-594 class, does not fit on this linear curve. The lead ship of this class was the Thresher (SSN-593) which was lost during sea trials. That loss delayed the building program and concentrated attention on submarine safety. Both were costly and added significantly to the average cost of this class. The average cost of the SSN-594 class was greater than the twelve submarines of the larger, more complex SSN-688 class. Because of these unusual circumstances associated with the SSN-594 class, it was eliminated from the CER calculation. The CER derived from using cost-weight data for the four classes of SSNs is $C = 206 + 45.3D$, which is displayed in Figure 4. The goodness of fit is shown in Figure 5. Even when the SSN-594 is included, the total error for the U.S. SSN category is only 6.4 percent and the average ship class absolute error is 6.0 percent.

As only four conventionally powered attack submarines (the SS-576 and the three ships of the SS-580 class) have been authorized and funded since 1956 there are few data points from which to develop a CER. The other diesel submarines produced in the U.S. (SS-572 and SSG-574) were of such special configuration as to not represent proper members of the category. In this situation the same approach as for aircraft carriers was assumed i.e., that the difference between nuclear and non-nuclear vessels was essentially constant and independent of displacement. Forcing the CER to satisfy the cost for the SS-580 class yields the result: $C = 46 + 45.3D$. The result is a category error of 2 percent for the cost of U.S. diesel submarines and an average ship class absolute error of 4.2 percent.

C. FLEET BALLISTIC MISSILE SUBMARINES (SSBNs)

For the first three classes of SSBNs each successive class grew in size, yet had a smaller average cost per ship (See Table 2). Accordingly, the CER for SSBNs is derived from essentially two data points -- one representing the average of the first three classes of SSBNs and the other being for the Ohio class SSBNs.[1] The exponential CER for SSBNs is $C = 392e^{.078D}$. A linear equation also provides a good fit to the data and essentially parallels the exponential curve except at the lower and upper ends. Figure 6 displays both curves. Data points for the five classes of SSNs are also plotted on Figure 6 although they are not used to derive the SSBN CER. Most of the SSN data

[1]The cost of the first seven Trident submarines is an estimate based on the TOA appropriated and budgeted as of December 1981.

8-25-83-4

Figure 6. COST VERSUS WEIGHT CURVES FOR FLEET BALLISTIC MISSILE SUBMARINES

points plot close to the linear CER. The percent difference using the exponential CER is 8.3 percent for the category error and 11.4 percent for the average ship class absolute error. Using the linear CER the category error is 10.5 percent and the average ship class absolute error is 13.1 percent. A comparison of the curve fit of both equations is portrayed in Figures 7 and 8.

D. DESTROYERS, FRIGATES, AND PATROL COMBATANTS

Patrol combatants (PGs) were included with destroyers and frigates to make one category. A linear equation that best fits the data is C = 11.1 + 37.8D. This equation yields a category error of 2.6 percent and an average ship class absolute error of 9.8 percent. Figure 9 displays the DD, FF, and PG curve, and the curve fit is depicted in Figure 10.

E. GUIDED MISSILE CRUISERS, DESTROYERS, AND FRIGATES

The curve resulting from applying the CER for this category of ships is also plotted in Figure 9. This category includes the CGs, DDGs, and FFGs, all equipped with guided missiles. These ships are sometimes referred to as "G" ships. The equation that provides the best fit to the data is C = 86.1 + 41.2D. The error for this category is essentially zero; however, the average class absolute error is 10.7 percent. The CER curve for this category nearly parallels that of the DD, FF, and PG category. This parallelism indicates that the incremental cost between missile ship and non-missile ship of equal displacement is about $85-100 million. The curve fit for the "G" ships is displayed in Figure 11.

The CG-47 (Aegis cruisers) are conventionally powered ships now under construction. It is assumed that the slope of the CER curve for Aegis CG category ships would be the same as for the FFG, DDG, and CG category. The average cost of the

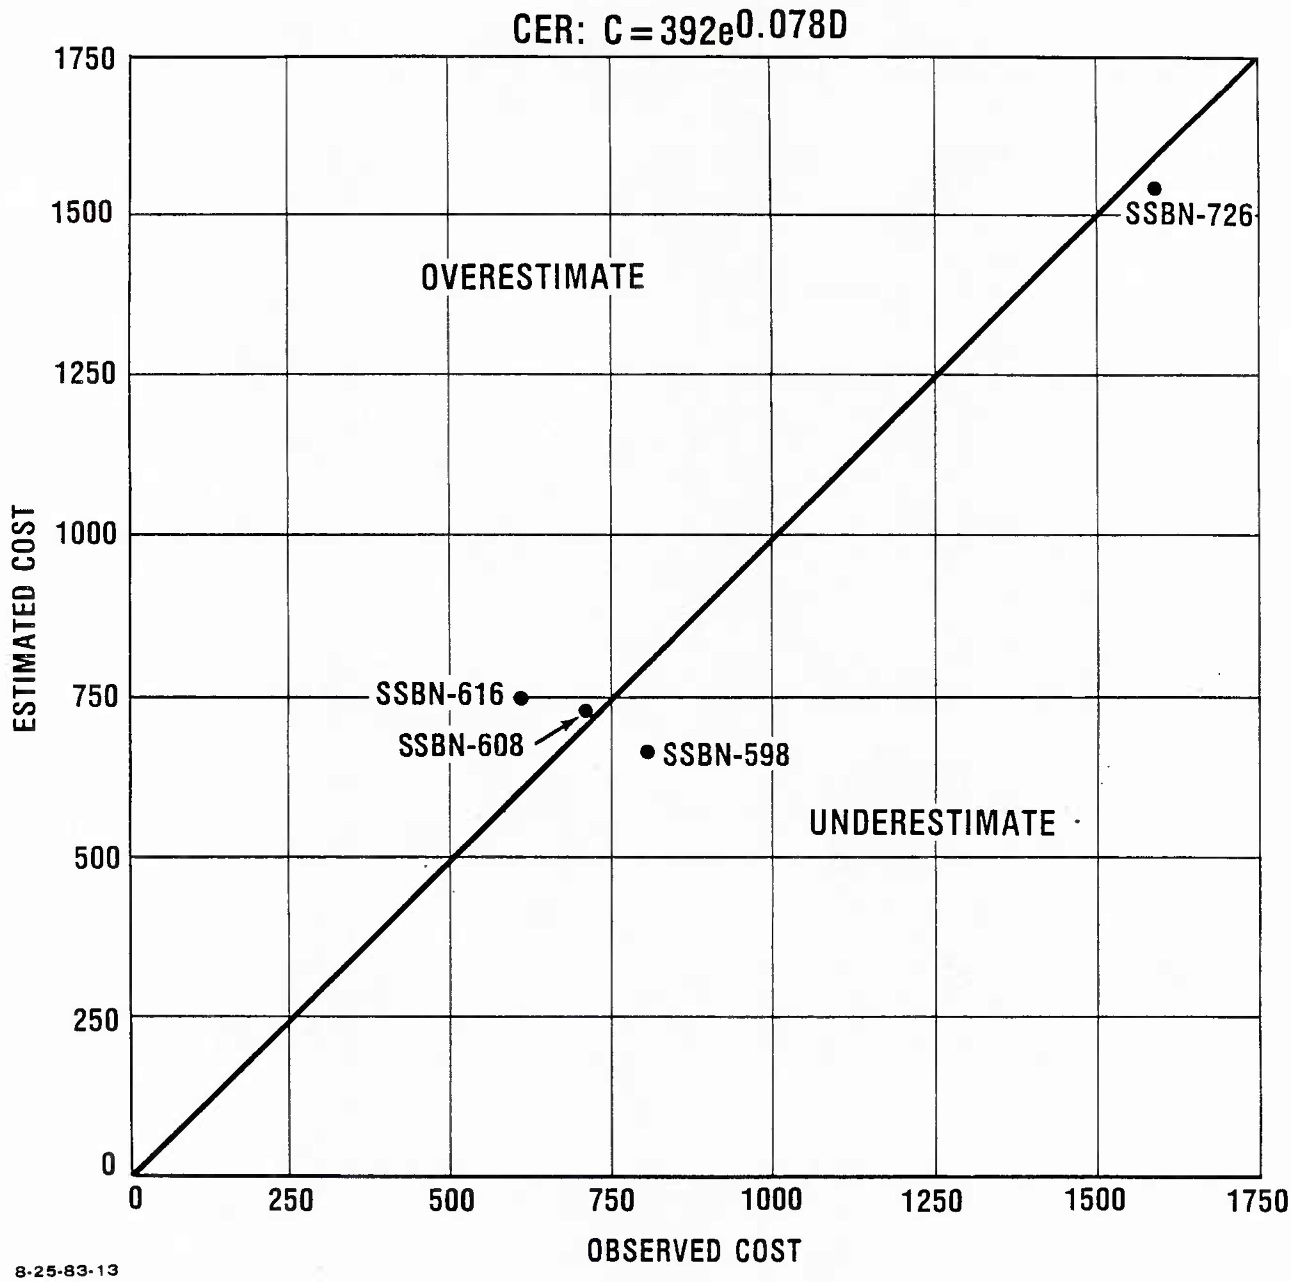

Figure 7. ESTIMATED COST OF FLEET BALLISTIC MISSILE SUBMARINES BASED ON WEIGHT VERSUS OBSERVED COST FOR SHIP PROCUREMENT USING AN EXPONENTIAL EQUATION

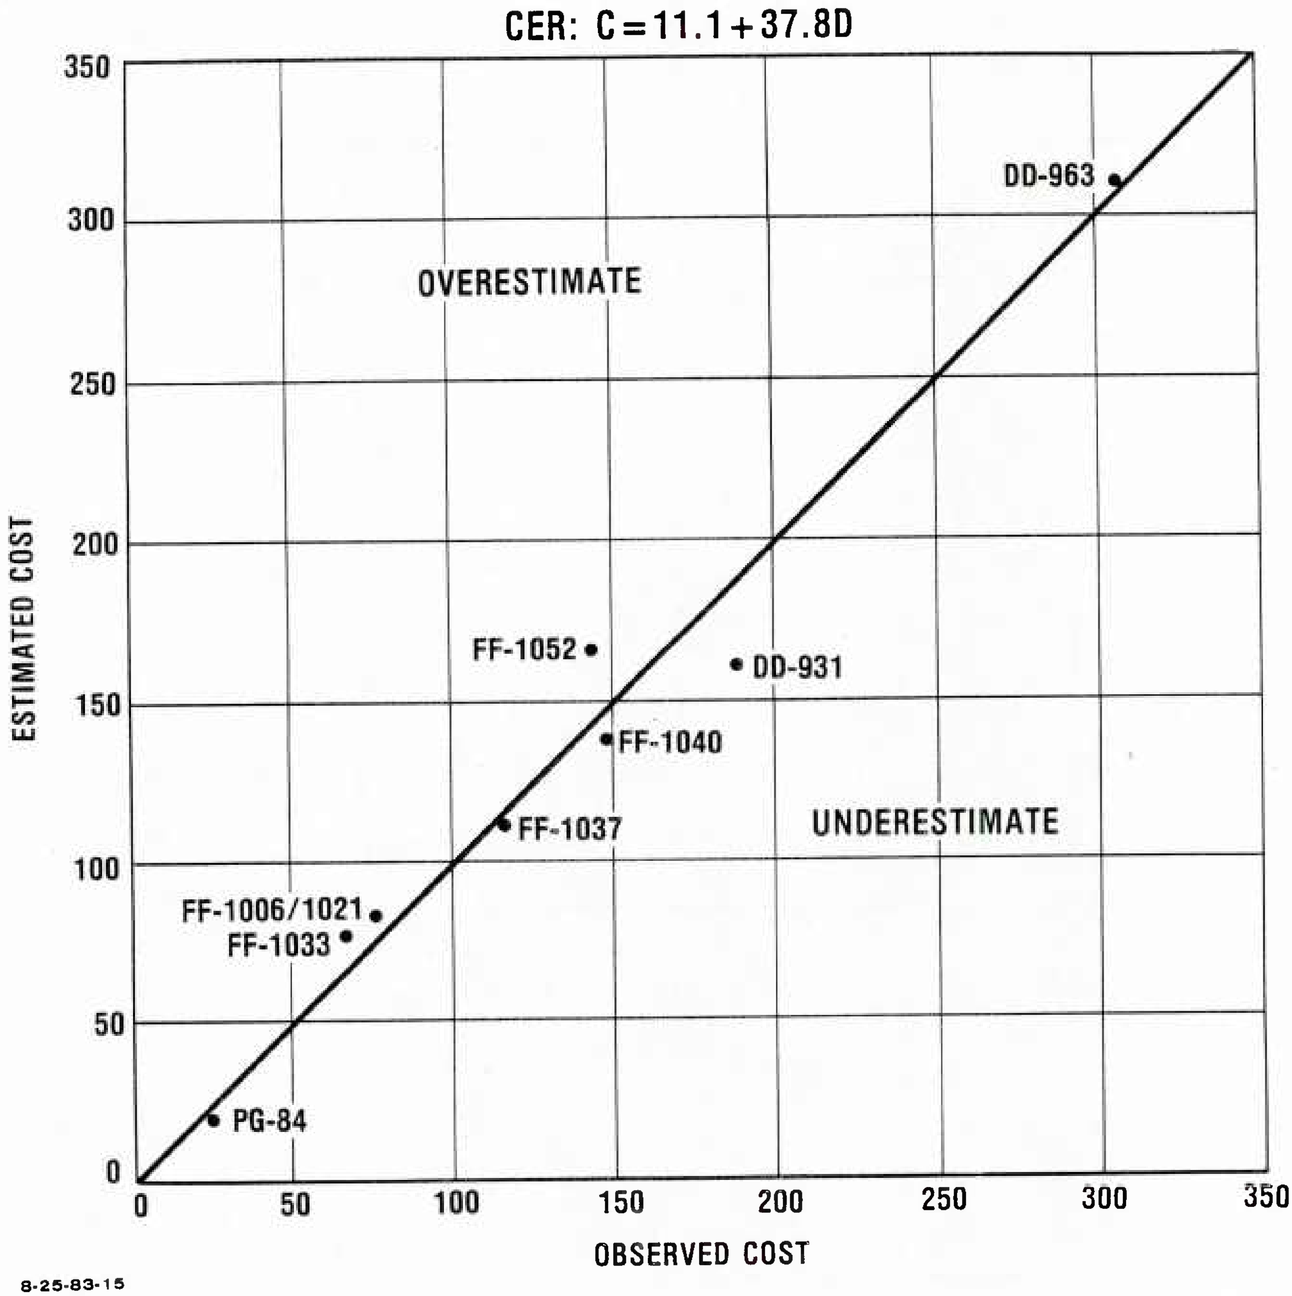

Figure 10. ESTIMATED COST OF DESTROYERS, FRIGATES AND PATROL COMBATANTS BASED ON WEIGHT VERSUS OBSERVED COST FOR SHIP PROCUREMENT USING A LINEAR EQUATION

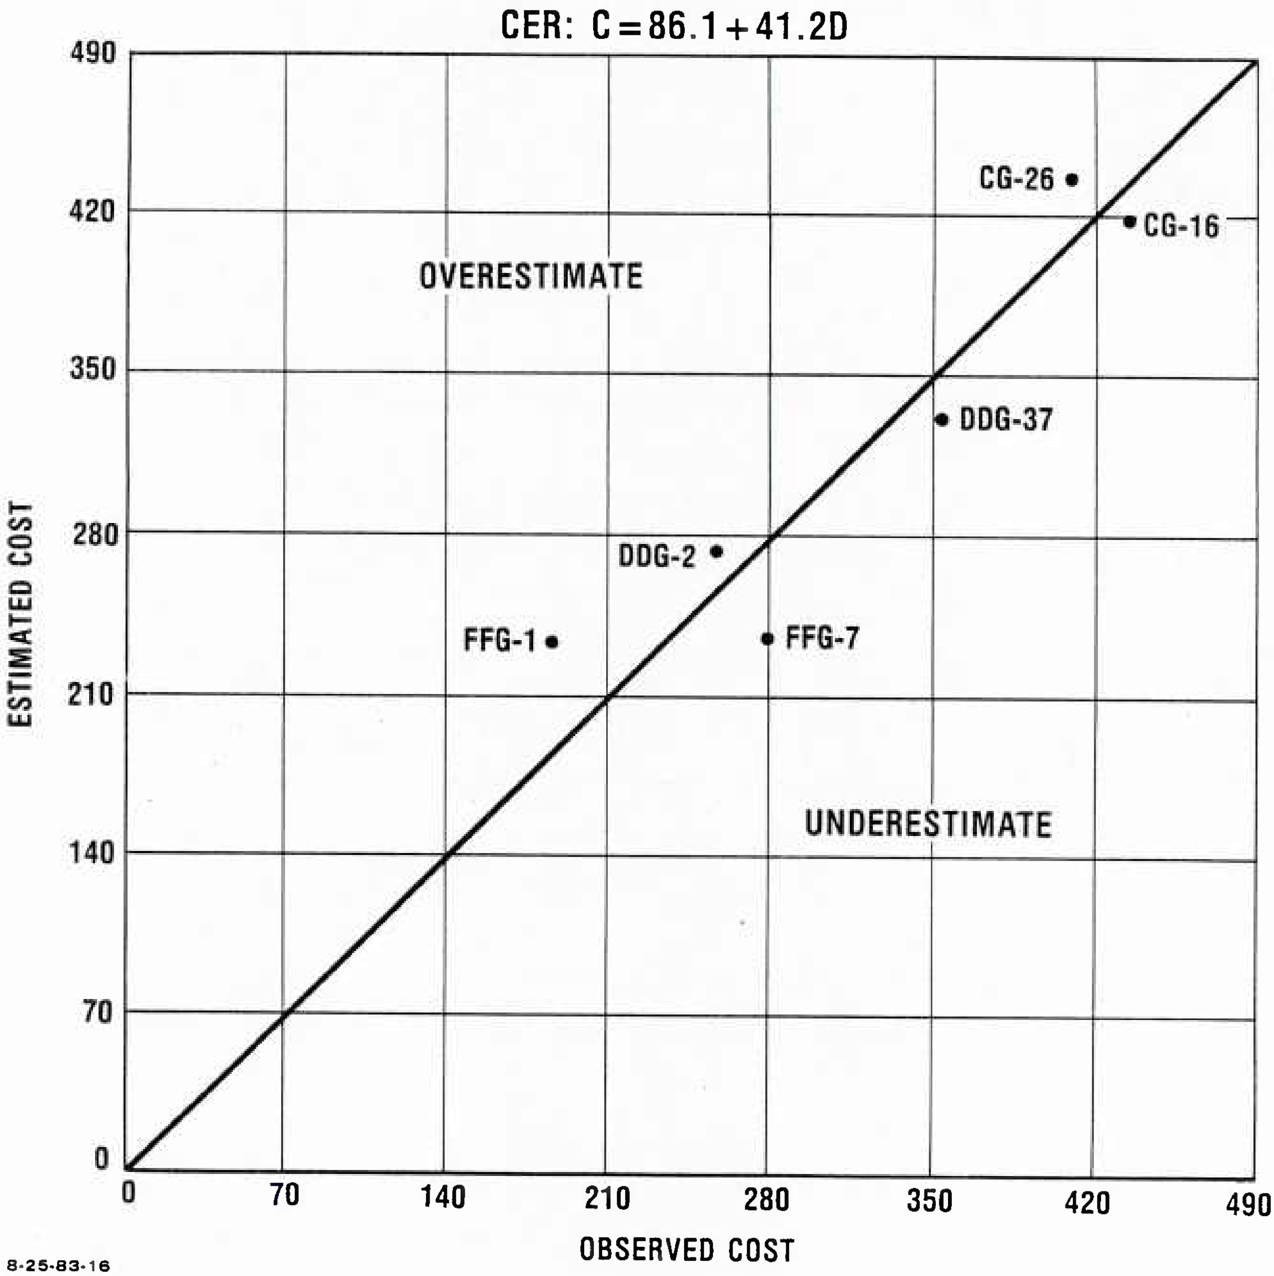

Figure 11. ESTIMATED COST OF GUIDED MISSILE CRUISERS, DESTROYERS, AND FRIGATES BASED ON WEIGHT VERSUS OBSERVED COST FOR SHIP PROCUREMENT USING A LINEAR EQUATION

first seven Aegis cruisers is $1,077 million with each ship having full load displacement of about 9,200 long tons. Thus the cost-weight ratio for this class of ship greatly exceeds that of similar-hull vessels constructed previously. The resulting CER is C = 698 + 41.2D. The reader is cautioned that this CER is based on the same slope as the FFG, DDG, and CG category and is based on a single data point.

F. GUIDED MISSILE CRUISERS (NUCLEAR POWERED)

This category includes nine nuclear powered cruisers built for the U.S. Navy. For eight of the nine the spread in displacement is only 2,200 tons. The remaining cruiser, CGN-9, was the first nuclear powered cruiser constructed and it underwent major design changes during construction. It is omitted from the derivation of the CGN CER for that reason. Since the remaining four classes of CGN have a narrow displacement and cost range that does not lend itself to deriving a valid CER, the incremental cost of CGNs above that for the FFG, DDG, CG equation was calculated as $390 million and applied to that equation. The same slope as the CER curve for FFG, DDG, CG was assumed. Figure 12 displays the resulting CGN equation C = 476 + 41.2D. This equation produced a category error of 6.8 percent and an average ship class absolute error of 10.8 percent. Figure 13 presents the curve fit of this equation.

G. AMPHIBIOUS SHIPS

The type of ships comprising this category are the LST, LSD, LPD, and LCC. The LPH and LHA amphibious assault ships were included with aircraft carriers and the amphibious cargo ships (LKA) are included in the underway replenishment ships category, because of their similarity in construction to Ammunition ships (AEs) and Refrigerated Stores ships (AFs).

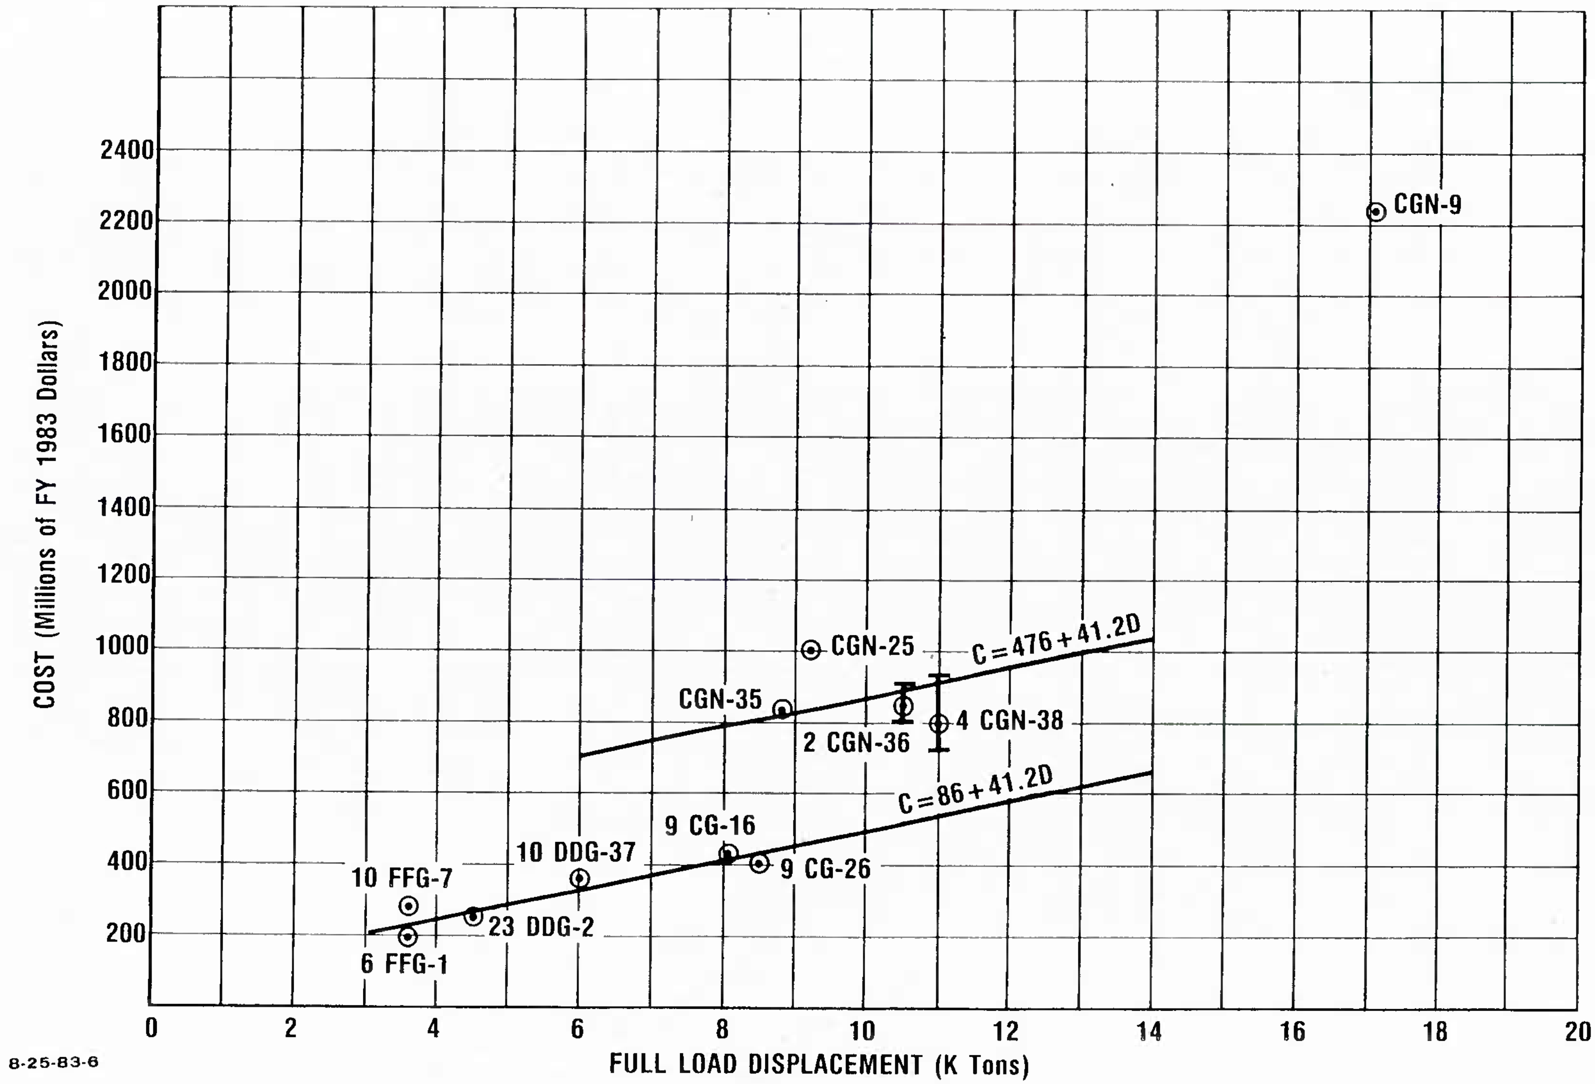

Figure 12. COST VERSUS WEIGHT CURVE FOR NUCLEAR POWERED CRUISERS

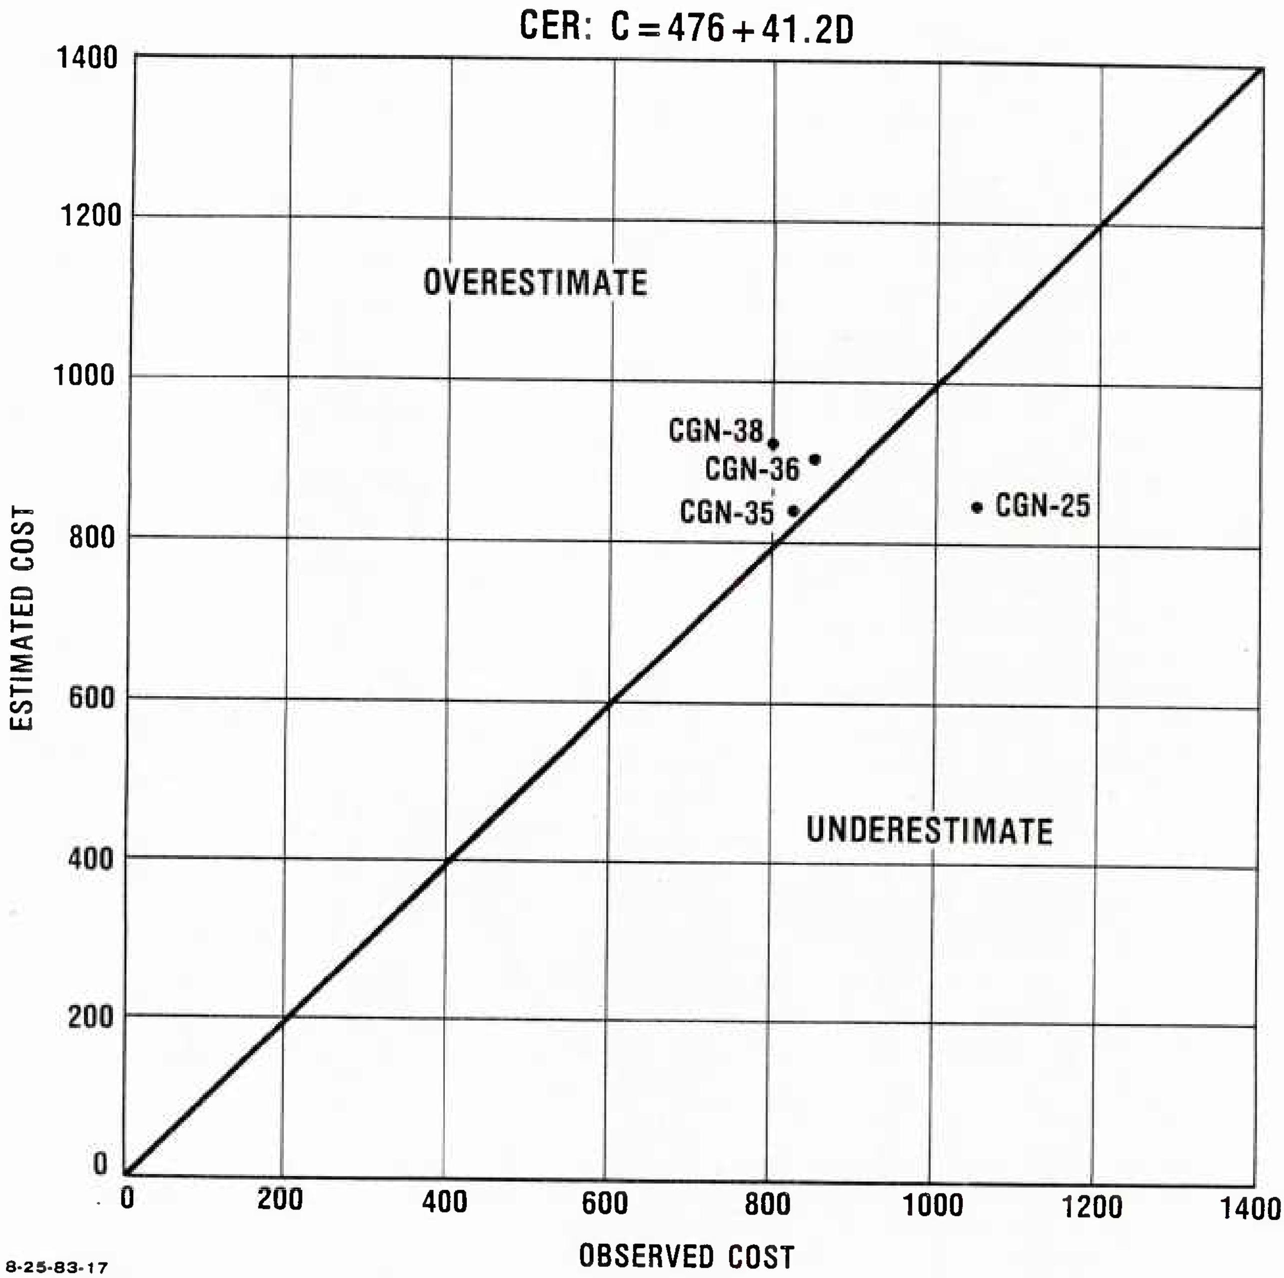

Figure 13. ESTIMATED COST OF GUIDED MISSILE CRUISERS (NUCLEAR POWERED) BASED ON WEIGHT VERSUS OBSERVED COST FOR SHIP PROCUREMENT USING A LINEAR EQUATION

From Figure 14 it is apparent that a good curve fit cannot be obtained from the data points. There are three conditions that prevent a good curve fit. First, the ships of the LSD-36 class which displace about 2,000 tons more than ships in the LSD-28 class, were constructed about twelve years after those in the LSD-28 class at about the same cost in constant dollars. Second, a somewhat similar situation exists with respect to the LPD-1 and LPD-4 classes. The three ships of the LPD-1 class were constructed by the New York Naval Shipyard. This same shipyard constructed the first three ships of the LPD-4 class, which displace about 2,300 tons more than ships of the LPD-1 class. These three ships had an average construction cost of $329 million; whereas, the last nine ships of the LPD-4 class were built in three private shipyards at an average cost of $218 million. Thus the larger LPDs were constructed at a lower average cost than were the smaller LPDs.

The third condition is the construction of the two LCCs. The lead ship was built in a Naval shipyard at a cost factor of 1.8 times the cost of the second LCC, which was built in a private shipyard. The resulting high average cost combined with a full load displacement that is about the same as the LPD-4 class produces very divergent data points. From the three curve fits attempted, an exponential equation $C = 33.2e^{.135D}$ was selected for this CER. The cost estimate error for this category is 6.7 percent. The average ship class absolute error is 20.7 percent.

The CER results obtained using a simple linear equation ($C = 17.8D$) produced an estimate error for this category of 21.7 percent and an average ship class absolute error of 34.7 percent. The goodness of curve fit to the data is displayed in Figures 15 and 16.

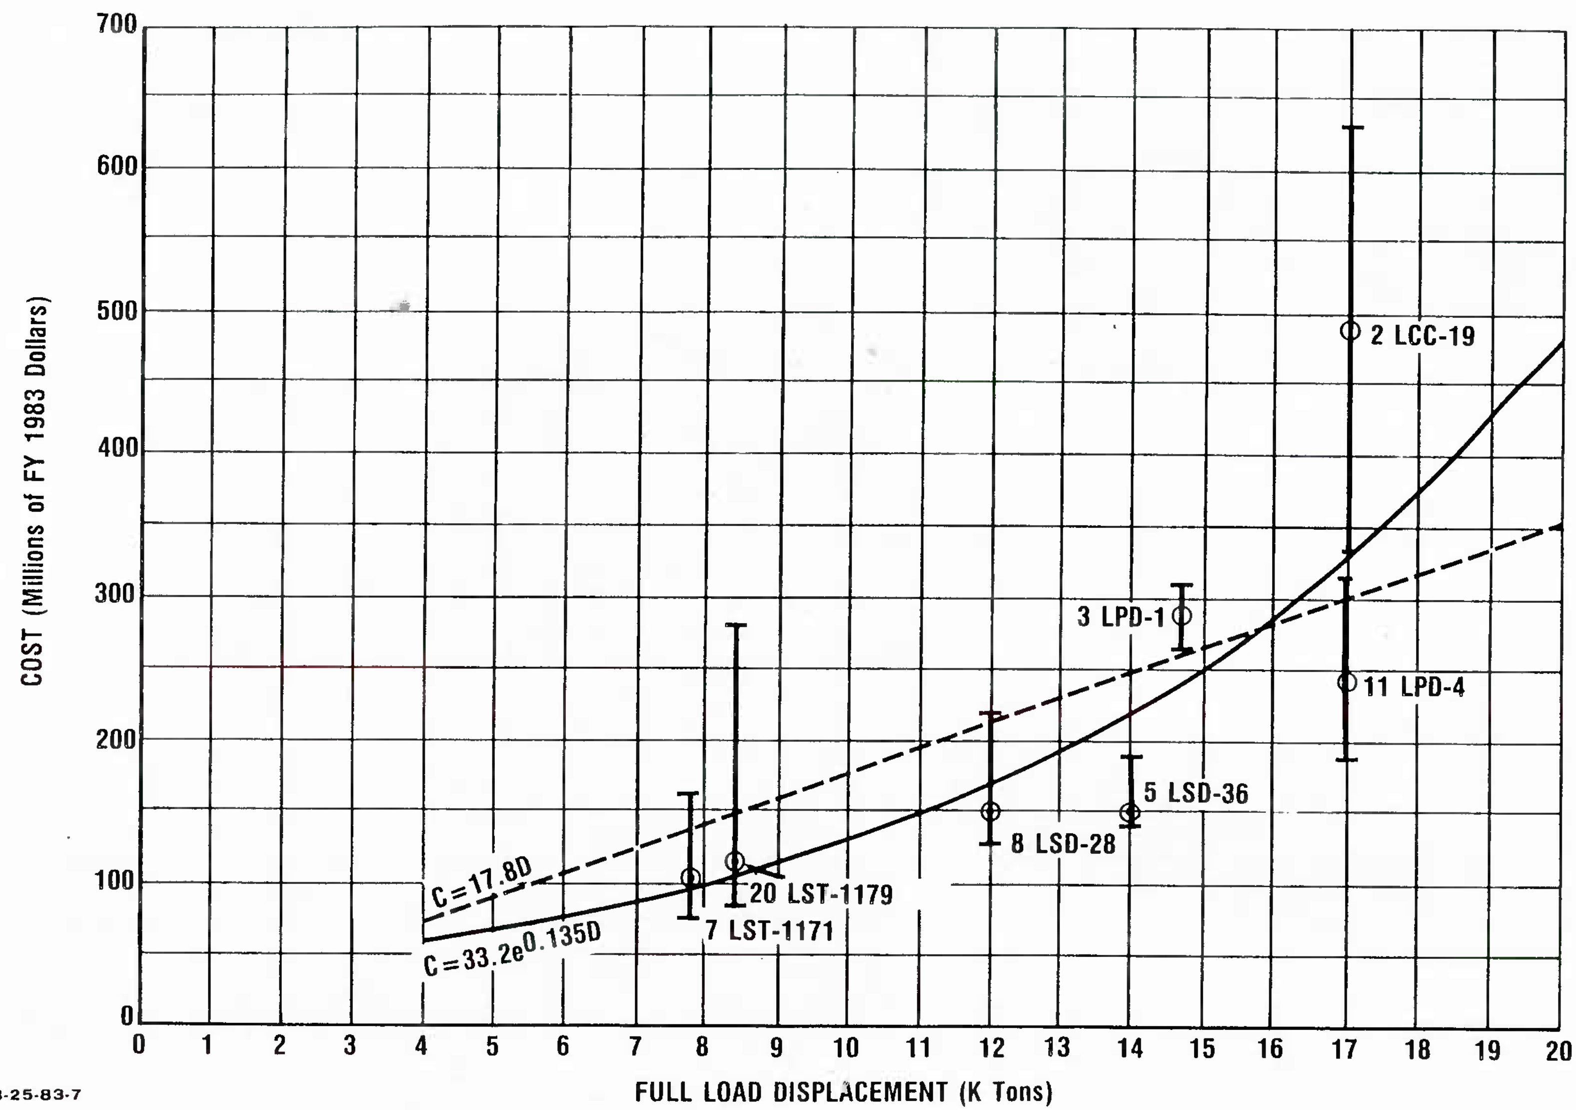

Figure 14. COST VERSUS WEIGHT CURVE FOR AMPHIBIOUS SHIPS

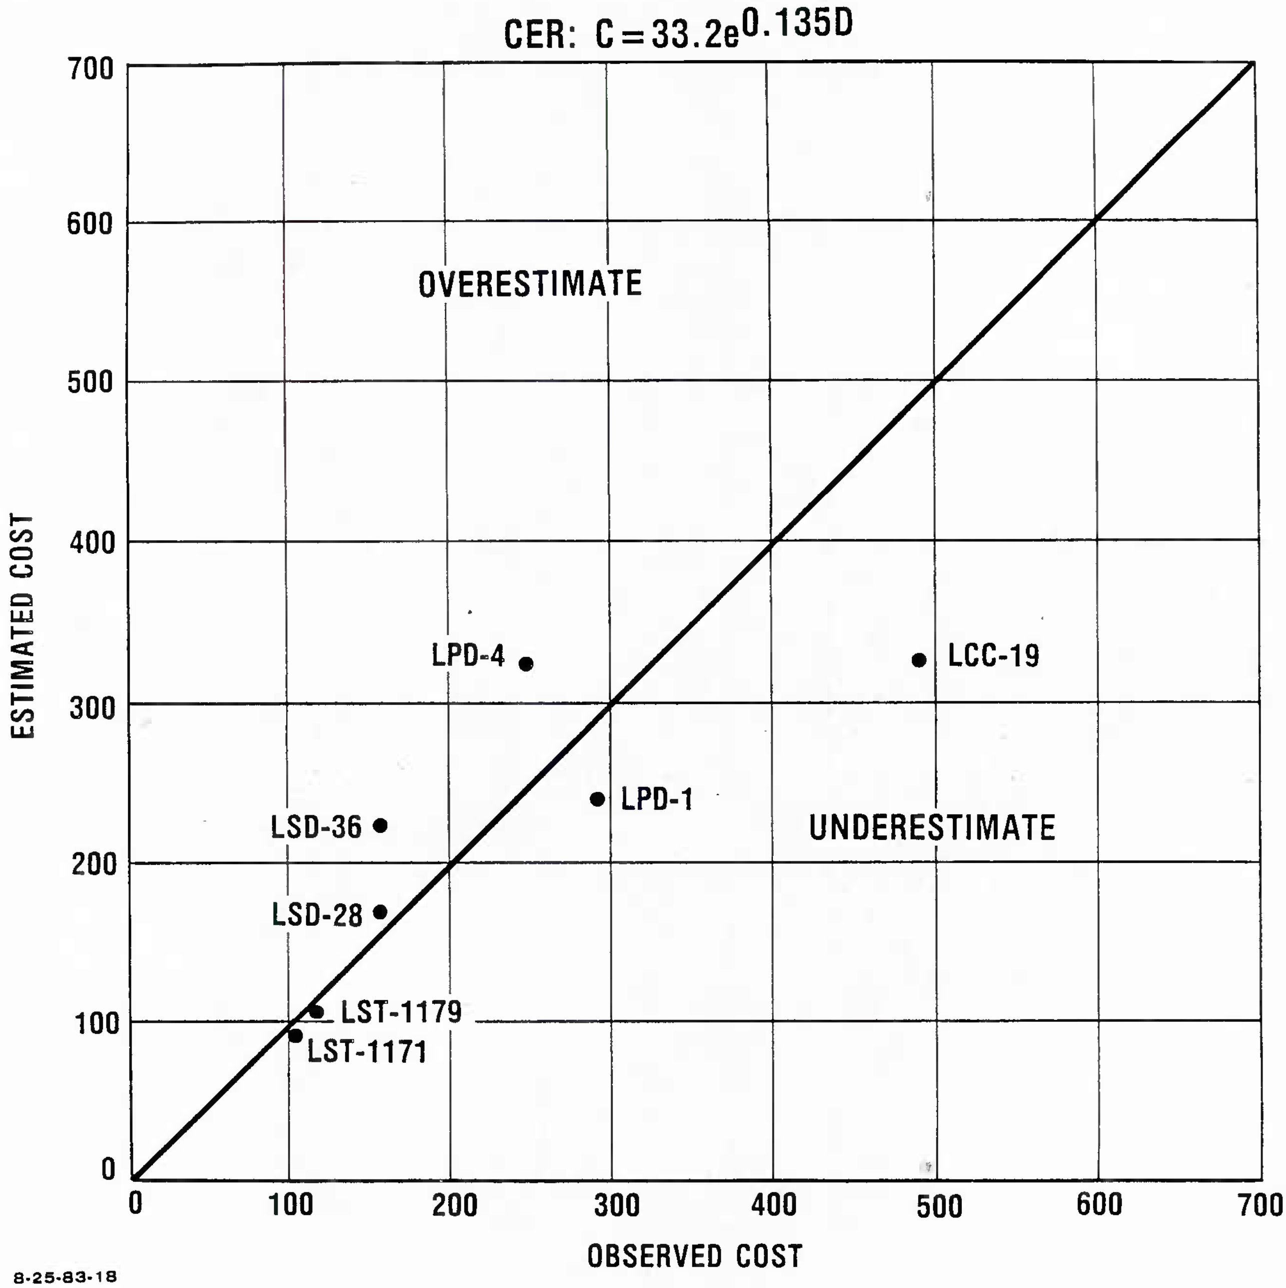

Figure 15. ESTIMATED COST OF AMPHIBIOUS SHIPS BASED ON WEIGHT VERSUS OBSERVED COST FOR SHIP PROCUREMENT USING AN EXPONENTIAL EQUATION

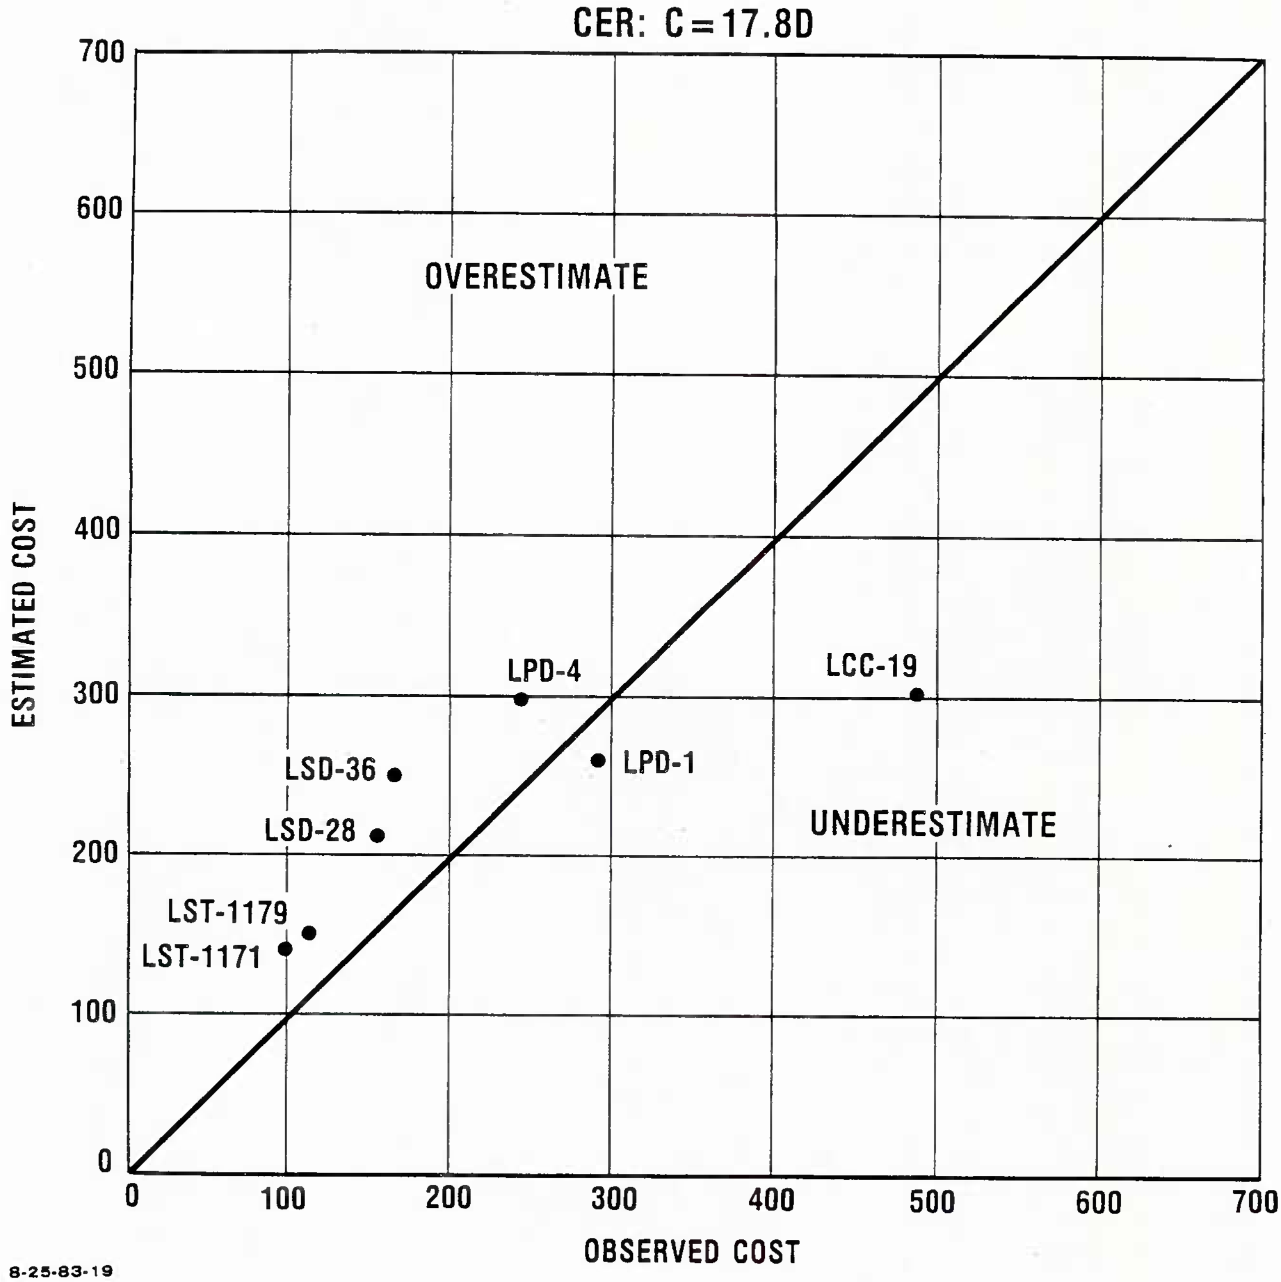

Figure 16. ESTIMATED COST OF AMPHIBIOUS SHIPS BASED ON WEIGHT VERSUS OBSERVED COST FOR SHIP PROCUREMENT USING A LINEAR EQUATION

H. UNDERWAY REPLENISHMENT SHIPS

The ships that comprise this category are the AE, AF, AFS, LKA, AO, AOE, and AOR. As mentioned in the preceding section, the LKAs are included in this category because of their similarity in construction to AEs and AFs. One group of ships tends to cluster around a point at the intersection of 18,000 tons displacement and \$140 million. The remaining AOs, AORs, and AOEs stretch out, but not in a consistent pattern.[1] Two equations result in curve fits that are about equal. They are a linear function $C = 37.4 + 5.54D$, and an exponential function $C = 92.2e^{0.024D}$. The category error using the exponential CER is negligible; the linear CER is about 2.6 percent. The average ship class absolute error for the exponential CER is 15.9 percent, and for the linear CER 18.1 percent. Both curves are displayed in Figure 17. The fit of the curves to the data is shown in Figures 18 and 19.

I. DESTROYER AND SUBMARINE TENDERS

The last category of ships for which an attempt was made to derive a CER is the AD and AS ships. Three different sorts of the data were fed into the curve fit model and none of the results produced a curve that would fit the data. An inspection of Figure 20 reveals that there is a variance of less than 3,700 tons displacement among the ship classes and less than \$140 million in construction cost. The data in Figure 20 can be interpreted as tending to cluster about a single point which has the values of \$370.6 million and 21,304 tons displacement.

---

[1]The AO-143 class ships with a displacement of over 1.4 times that of the AO-177 class ships were constructed at about 77 percent of AO-177 class average cost. This is not a very good comparison because only the first three AO-177 class ships have been completed and are used to calculate the class average cost.

J. SUMMARY

The methodology used in the attempt to derive CERs for twelve categories of ships was presented followed by the results of entering cost and displacement data into three computerized curve fit equations. In some instances the data were too clustered to produce an acceptable CER; e.g., Destroyer and Submarine Tenders, and in other cases only one data point was available; e.g., CVN-68, SS-580, and CG-47 classes. In these latter cases assumptions were made that a parallel curve having a constant differential value was appropriate.

For each category of ship the range of errors between the CER estimate and the observed cost were identified and both the ship category error and the average ship class absolute error were presented. These data arranged by ship category are tabulated in Table 2.
