Purpose

This report provides demographic information about the officers and enlisted personnel of the United States Army as of 30 November 1976. For purposes of comparison, it also includes selected information gathered from Army-wide surveys in 1973, 1974, and 1975. Individuals who desire more detailed reports on 1973, 1974, and 1975 data should consult DAPC-PMP Report No. 4-74-S, Army Personnel Composite as of 30 November 1973, DAPC-PMP Report No. 3-75-S, Army Personnel Composite as of 30 November 1974, and DAPC-MSF Report No. 21-76-S, Army Personnel Composite as of 30 November 1975.

Method

The Army Sample Survey is a multipurpose instrument administered worldwide on a quarterly basis. Most of the data in this report was collected as part of the 30 November 1976 Army Sample Survey. Statistics from any other sources besides the 30 November 1976 Army Sample Survey are noted on the particular tables.

Sample Population

The sample for all surveys cited in this report consisted of a randomly selected group of active duty officer and enlisted personnel.

FACTORS AFFECTING ACCURACY OF SURVEY DATA

Reliability

a. Definition. Survey accuracy (reliability) is generally expressed in terms of confidence probability and error intervals. Confidence probability (e.g., 95%) refers to the fact that if a survey were administered over and over again to the same population, a certain percentage (95%) of the time the survey results will fall within a specified error interval. The error interval (e.g., $\pm 4\%$) is the range of percentage points above and below a given value in which the repeated results would almost always be expected to fall.

In other words, in a survey with a reliability of $95\% \pm 4\%$, if the same population were resampled, 95 out of 100 samples would provide an estimate within plus or minus four percentage points of a given value. If the accuracy is $95\% \pm 4\%$ and the survey data indicates responses of "Yes" 70% and "No" 30%, then 95 times out of one hundred, the sample data will fall between these intervals: "Yes" 66% - 74%, "No" 26% - 34%.

b. Assumptions underlying the reliability levels. Three important assumptions underlie the reliability figures expressed for this survey.

First, it is assumed that the sample was random. The sampling plan required that respondents be selected by social security numbers so that this assumption would be supported.

Although selection procedures differ at the installations, any error is assumed to be randomly distributed. Comparison of demographic data supports this assumption.

Second, in determining the reliability of the data it was assumed that the population totals at least several thousand for each independent variable (column heading). Army-wide this is usually the case. For example, there are many thousand women in the whole army population, or similarly, there are many thousand E-5's. In cases where there are fewer than 2000-3000 in the specified population, the reliability statistics err on the side of making too stringent a demand for sample size. In this way reliability limits at least as high as those specified are assured.

Reliability for crosstabulations is determined for each multiple choice response or group of responses in comparison to all the other response choices to a question. The third assumption is that 50% of the sample respond to one choice, with the remaining 50% distributed among the other choices. The effect of this assumption is to again apply a strict standard to ensure that the specified reliability is met. As the survey respondents collectively favor one choice more than another, reliability increases.

c. Meaning of column notations on Tables. Based on the above assumptions, the accuracy of the independent variables generally is $95\% \pm 5\%$ or better. However, if a column of an independent variable has an asterisk (*) below it then the reliability level of data in that column is between $95\% \pm 6\%$ and $95\% \pm 9\%$.

Nonresponse Bias

The overall nonresponse rate was 32%. It was not possible to determine if personnel who did not respond to the survey differed significantly from those who did. Obviously, any differences between the two groups could bias the results.

Personal Bias of the Respondent

Individual respondents may have had a conscious or unconscious desire to take sides for or against the organization sponsoring the survey, and to protect any personal interest at variance with those of the proponent.

Variable Responses to Items

Included in this factor are different interpretations of the same situation given by the same person or given by different persons. Variability of response may be due to many factors: the psychological state of the respondent, a mismarked response, an intended distortion of the truth, misunderstanding of the question, or computer processing errors.

Comments or Information Request

Comments on this report or requests for other reports cited within should be forwarded to:
