ABSTRACT

This thesis determines the relationships of helicopter design parameters by first depicting graphically all possible pairings of selected design parameter values and then, secondly, depicting graphically respective curve fits for the data point plots which meet an acceptance criteria. In generating the curve plots, the specific constants of each curve equation are determined, thus allowing the designer the ability to derive quantitatively the values of many of the design parameters heretofore selected by trial and error methods.

I. INTRODUCTION

The evolution of helicopter design has proceeded far beyond the starting point where design decisions were based on a 'trial and error' criteria. In major helicopter industry, the design process has evolved to a largely technical discipline where, with the noted exceptions of technological breakthroughs which cause a drastic departure from the norm (an example being the Hughes NOTAR, a helicopter without a tail rotor!), a new helicopter design is built by piecing together critical design parameters in a fashion dictated by past successful designs. Those critical design parameters, logically, are determined by the intended user's requirements (e.g., carrying capacity, and mission (scout vs. utility vs. attack)), performance requirements (e.g., speed, climb, and range), and the geometric requirements (e.g., length, and width).

Definite relationships between these critical design parameters (30 have been selected), are frequently unavailable, or unknown, and are not used during the preliminary design process. By examining all possible pairings, or permutations, across a large number of present helicopter designs (10 have been chosen), one could produce equations of curves which would consistently, accurately and quickly produce the quantitative value for the design parameter a designer seeks.

A. OBJECTIVES AND SCOPE

The objective of this thesis is to determine if quantitative relationships exist between the pairings of critical helicopter design parameters. If they do exist, specific

equations of curves, forming a curve fit of the data, and specific constants, are to be determined.

II. APPROACH TO THE PROBLEM

Thirty design parameters were selected and a data base was compiled of the values of these design parameters for 10 helicopters. The 10 helicopters chosen were selected purposely to represent a varied mix of single-mission aircraft (utility, heavy utility, scout or observation, and attack), and old and new technology, ranging from the 1950's to the late 1970's, to lend creditability to the resulting relationships for use in any future preliminary helicopter design process. Selected design parameters, and the respective values for each of the chosen helicopters are listed in Appendix A. A planform and abstract picture of each helicopter, for referencing, is contained in the same Appendix. Table 1 is a brief summary which illustrates the diversity of the helicopters chosen to compile the data base for this thesis.

Pairing each parameter singularly against each other yielded 435 permutations at the start of the evaluation. The pairings are referenced by 2 numbers. For example, the pairing number '1-30' pairs the first design parameter, Main Rotor Blade Radius, against the thirtieth design parameter, Maximum Gross Weight. Appendix B contains a complete listing of pairings. A simple data point graph (X vs. Y) was made of each pairing and, for the graphs that showed a clear relationship existed, data points are curve fitted yielding a curve equation with specific constants. Both the singular data points, and the curves, generated from the curve equations, are depicted graphically, reinforcing the closeness of the curve fits, and that a relationship does indeed exist.

TABLE 1
Summary Characteristics of Chosen Helicopters

Military Designator	Weight Class	Primary Service	Year of Manufacture	Year of Technology	Mission Purpose
AH-64	Medium	USA	1983	1970	Attack
CH-53C	Light	USA	1969-78	1960	Observation
SH-3H	Medium	USN	1961-72	1950	Utility
S-76	Medium	USN	1982	1970	Utility
UH-60A	Medium	USA	1979	1970	Utility
CH-54B	Heavy	USA	1974	1960	Utility
CH-53D	Heavy	USN (MC)	1969	1960	Utility
CH-53E	Heavy	USN	1981	1970	Utility
AH-1S	Medium	USA	1970-81	1960	Attack
UH-1H	Medium	USA	1965-76	1950	Utility

In addition to original programs, two pre-existing computer programs were used to facilitate the accomplishment of the thesis objective. The data point plots were generated with 'Helicopter Data Display', written by Captain Gary Bishop, USA, [Ref 1], and the curve fit evaluation was accomplished with 'Crvfit', a Hewlett-Packard hand-held computer program, written by Commander Pat Sullivan, USN, [Ref 2]. The 'Helicopter Data Display' graphic output was re-sized to meet the requirements for thesis submission, and the pre-existing data base revised with additions of data from 3 more helicopters, a deletion of 1, and correction of some incorrect data. The 'Crvfit' program was used as is, with an acceptance criteria, called the correlation factor, of .8 or greater.

III. SOLUTION TO THE PROBLEM

Of the first 435 pairings, 153 were cut from consideration following an initial consultation with Thesis Advisor Prof. Donald Layton based on his own expertise. Those pairings disregarded from further evaluation are indicated by a prefixed "XX" in Appendix B. An example of pairings which were disregarded outright were those involving 'Degree Twist of Blades'. By experience, and verified thru conversations with helicopter company representatives, 'Twist of the Blade' has in the past been decided on by a 'what's on the shelf' selection criteria, thus explaining why some companies produce helicopters predominantly with a -10 degree twist, while others produce helicopters predominantly with a -8 degree twist, or, a 0 degree twist. 282 simple X-Y plots of the remaining pairings were then generated, with the first number of each pairing designated as the X-abscissa, or horizontal axis, and the second number, as the Y-ordinate, or vertical axis. Plots appear in Appendix C and are referenced with figure numbers consistent with the method used to reference the initial pairings (Example: Fig 1-30). The selection for further evaluation for determining curve fits was accomplished by empirically judging whether the data points tended to show that a relationship existed. Those figures referenced with a suffix 'a' indicate that a relationship does exist and a data point curve fit follows. The two examples are illustrated in Figures 3.1 and 3.2.

The data of the data points plots that were questionable were submitted to the Crvfit program which made the final decision as to whether there was an interrelationship with a resulting program correlation factor of .8 or greater.

Figure 3.1 Data Point Plot Chosen to be Curve Fitted.

Figure 3.2 Data Point Plot Chosen Not to be Curve Fitted.

At the same time, the 'Crvfit' program determined which of 4 (four) curve types, linear (Type 1), exponential (Type 2), logarithmic (Type 3), or power (Type 4), best fit the data points plotted. An example of one of each of the 4 curves is illustrated in Figures 3.3 through 3.6. Curve fits for the respective pairings, referenced with a suffix 'b', indicating curve fit (Example: Fig 1-30b), and which includes the best curve fit equation, follow their respective data point plots in Appendix C.

Figure 3.3 Example of Type 1 Curve Fit.

Figure 3.4 Example of Type 2 Curve Fit.

Figure 3.5 Example of Type 3 Curve Fit.

Figure 3.6 Example of Type 4 Curve Fit.

IV. RESULTS AND CONCLUSIONS

282 pairings were evaluated to determine whether an interrelationship existed between the selected design parameters. 185 were determined to produce positive curve fit data which met or exceeded the chosen correlation factor. Of the 30 design parameters selected for evaluation, the parameters Maximum Gross Weight and Operating Weight were most interactive, resulting in positive quantitative relationships with 16 other parameters. This is understandable for both parameters are geometric parameters, driven by mission and performance requirements and both influence many of the others. 10 design parameters had no influence, resulting in no relationship with any other parameter. A demonstration of the validity of the derived relationships is illustrated as follows where both the curve fit equation, and an alternate method (used in AE 4306 Helicopter Design Manual [Ref 3]), are used to generate specific design parameters of Gross Weight and Tail Rotor Radius. The results are compared to an existing, flying helicopter.

Required: Compute Gross Weight, MGW, as a function of Tail Rotor Radius, RTR, given as 2.6 feet.

Curve Fit - $MGW = 324.88 \times RTR^{2.3829} = 3166 \text{ lbs}$
Equation

AE 4306 - $MGW = 591.716 \times RTR^{2.0} = 4000 \text{ lbs}$
Design Manual
(Alternate Method)

2.6 feet is the actual tail rotor radius of the OH58C Army Observation/Scout Helicopter whose actual Gross Weight is 2550 lbs.

By comparison, the curve fit equation generates a value of Gross Weight 24% above actual design, whereas the alternate method generates a value 52% above actual design.

Table 2 lists the number of relationships, or the influence of each design parameter upon each other.

A. CONCLUSIONS

The objective of this thesis has been achieved by establishing the clear relationships that exist between selected Helicopter design parameters. The curve fit equations that were derived, and the specific constants for each equation, provide the designer, be he professional, in the industry, or student, a means to quantitatively derive values of design parameters that are encountered during the preliminary design process.

Until technological breakthroughs force a drastic departure from the established design norms developed over the last 30 years, the curve fit equations can produce a quantitative, quicker, and more optimum solution than the methods employed to date.

APPENDIX D

FORTRAN AND HEWLETT PACKARD COMPUTER PROGRAMS

A. 'CRVFIT' (DETERMINATION OF CURVE FIT EQUATIONS) HP PROGRAM

This program will determine a curve of best fit to a set of data points. The four standard curve types the program handles are:

1. Linear $y = b \cdot x + a$
2. Exponential $y = a \cdot e^{bx}$ ($a > 0$)
3. Logarithmic $y = b \cdot \ln(x) + a$
4. Power $y = a \cdot x^b$ ($a > 0$)

The program will compute the coefficients a and b in the equation of one of the above four curve types as well as compute a value r^2 called the coefficient of determination which is a measure of the goodness of fit. Once a set of data has been fit to a given curve type, a prediction may be made for the y -value given a new x -value, or a prediction may be made for the x -value given a new y -value. The functions available on the top row of keys on the keyboard are indicated in the following diagram.

These same functions are referenced in the examples and instructions by enclosing the name of the function on the key in square brackets [].

Example 1: Find the straight line which best fits the following data:

(1.1, 5.2), (4.5, 12.6), (8.0, 20.0),
(10.0, 23.0), (15.6, 34.0)

Then predict y when $x=20$ and predict x when $y=25$.

LOAD "CVF" PROG. into the 41C and SIZE 027. GTO "CVF" and go into USER mode. This puts the program counter in ROM and makes the curve fit functions available on the top row of keys. Pressing [INITIALIZE] will initialize the program. This clears registers R11 thru R24 so that a new set of data may be entered. In this example the 5 data points will be entered using the [Σ+] key. Key in each pair as x ENTER y and push [Σ+].

<u>Do:</u>	<u>See:</u>
[INITIALIZE]	1.0000
1.1 ENTER 5.2 [Σ+]	2.0000
4.5 ENTER 12.6 [Σ+]	3.0000
8.0 ENTER 20.0 [Σ+]	4.0000
10.0 ENTER 23.0 [Σ+]	5.0000
15.6 ENTER 34.0 [Σ+]	6.0000

All the data has now been entered and the parameters for the curve will be computed next. Since in this example we are interested in a straight line we key 1 (J=1) and push [SOLVE TYPE J]. When execution stops the values a, b, and r are available in the stack as:

Z: r	and are also stored as	R08: b
Y: a		R09: a
X: b		R10: r

For this example:

Z: r=0.999035140.
Y: a=3.499147270
X: b=1.972047542

The value r ranges between -1 and +1 and is a measure of how well the data fits the given curve type. The sign of r indicates whether the data is positively or negatively skewed. The closer r is to one of the extremes ± 1 the better the fit. For this example the line has positive slope and the fit is extremely good (all sample problems seem to work well).

Having computed the values b and a (these remain stored in R08 & R09 until new data is input) we can determine new points along the line. Key in 20 and push [y] for the predicted y-value. y=42.94009811 when x=20. Key in 25 and push [x] for the predicted x-value. x=10.90280649 when y=25.

COMPLETE INSTRUCTIONS FOR "CVF"

(Keyboard Operation)

- 1) Key GTO " ", SIZE 027 and go into USER mode. The keyboard functions should now be now available on the top row of keys.
- 2) Press [INITIALIZE] to initialize the program. This step clears data registers R11 thru R24 inclusive. These registers will be used to accumulate the data for all four curve types. The display will show 1.

3) Key in the next data pair (x,y) as x ENTER y and push [I+]. Repeat this step for all data pairs. The display will stop with a count of the number of the next data pair to be entered. This feature makes it possible to enter only the y-values when the x-values are consecutive integers which start counting from 1. In this case the display provides the x-values which need not be entered. If an improper data pair has just been input with the [I+] key, then immediately pressing R/S will delete the pair. Otherwise an improper or undesired data pair can be deleted by re-entering both x and y and pressing [I-].

4) As data pairs are entered it is possible that some x or y value is negative or zero. In these cases only one or two of the four curve types may be applied to the data. The four curve types and their respective equations are as follows:

Type J	Name	Equation
1	Linear	$y = b^*x + a$
2	Exponential	$y = a * e^{bx} \quad (a > 0)$
3	Logarithmic	$y = b * \ln(x) + a$
4	Power -	$y = a * x^b \quad (a > 0)$

If any x-values are negative or zero then only types 1 & 2 are feasible curves. If any y-values are negative or zero then only types 1 & 3 are feasible curves. If in any data pair both x and y are negative or zero then type 1 is the only feasible curve. The a coefficient must be positive for curve types 2 and 4.

5) After all data pairs have been input the next step is to select the desired curve type. This step can be accomplished in one of two ways. Under either option, the 41C should not be interrupted or else there is a possibility that the data registers will not be returned with their normal contents.

a) To fit a particular curve type, key in the number 1-4 for that type and press [SOLVE TYPE J]. The stack returns with:

Z: r	and these parameters	R07: J=curve type
Y: a	remain stored in	R08: b
X: b		R09: a
		R10: r

Step a) may be repeated at any time for any of the four curve types.

b) If all data input is positive then pressing [SOLVE BEST] will automatically choose the curve of best fit according to the curve type with largest absolute value of r . In this case the stack returns with:

T: r	and these parameters	R07: J =curve type
Z: a	remain stored in	R08: b
Y: b		R09: a
X: J =best curve type		R10: r

6) Predictions for new x or y values may be made only after step 5) has been completed. Predictions for new values are based on the settings of flags F08 and F09 which are automatically set during the fit process in step 5). The status of flags 8 and 9 for the four curve types are as follows.

	<u>Flag 8</u>	<u>Flag 9</u>
1 Linear	clear	clear
2 Exponential	set	clear
3 Logarithmic	clear	set
4 Power	set	set

In general the user need not be concerned with these flag settings, and F08 and F09 are not available for other use and must not be disturbed. To predict y given x , key in x and press [$\hat{y}$]. To predict x given y , key in y and press [$\hat{x}$]. In both cases the predicted value is left in the X-register.

7) New data may be added or deleted at any time via the [$\Sigma+$] or [$\Sigma-$] keys. However, step 5) must be performed after updating the data before any new predictions can be made using step 6). The parameters a and b are automatically destroyed after input of new data.
