ABSTRACT

A computer-aided data acquisition system was developed and a microthermocouple probe constructed to obtain thermal distributions in turbulent buoyant jets exposed to a cross-flowing ambient fluid. The system performed high speed temperature measurements as a microthermocouple probe was automatically traversed through a sequence of preprogrammed positions under the control of a microcomputer. Operability of the apparatus was demonstrated by measuring temperature distributions in planes perpendicular to the streamwise axis of jets from which contour plots of temperature were generated. Using temperature distributions along with velocity distributions allow buoyant jet characteristics to be computed, including the entrainment rate of ambient fluid, jet trajectory, and heat transfer to the ambient. The experimental technique is discussed and temperature contour plots for a jet at various planes are presented.

I. INTRODUCTION

Buoyant jets are very common in nature. We see them in the form of exhaust gases emitted from smoke stacks of refineries, mills and ships. We see them in the form of heated waste water expelled into the sea from power plants and from the main propulsion condensers in steam driven ships and submarines. It is no wonder that the fluid mechanics and heat transfer characteristics of buoyant jets have been of interest to environmental, civil and mechanical engineers for decades. To evaluate their ecological impact, and of most recent interest, to harness buoyant jets as a means of detecting military targets and guiding weapons, it is necessary to develop models which accurately predict their trajectory and decay.

Most studies to date have dealt with buoyant jets rising through a quiescent ambient fluid; however, in nature most problems involve flowing ambient fluids. Relatively little experimental work has been done with buoyant jets in cross-flow and, according to Hilder [Ref. 1], the trajectories of jets and the entrainment rates of ambient fluid predicted from previous work do not agree well with one another. Most mathematical models of buoyant jets in crossflow assume Gaussian profiles for velocity and temperature. Nickodem [Ref. 2] has shown through experiments that in fact, the

Gaussian profiles of velocity are altered by crossflow. This leads one to suspect that the same may be true for the temperature profiles.

The objective of this work was to develop a system to thermally map a buoyant jet in crossflow. Then, by measuring both velocity and temperature distributions, improved computations of entrainment, trajectory and heat transfer characteristics of jets can be made thereby giving rise to more accurate models.

II. BUOYANT JETS DISCHARGED TO A CROSSFLOW

A. PROPERTIES OF BUOYANT JETS

A buoyant jet is characterized by a momentum and a density differential between the jet and its surrounding ambient resulting from a variation in temperature and/or fluid concentrations. Therefore, fluid motion in the jet is governed by both inertial and buoyant forces. The non-dimensional ratio of these forces, known as the densimetric Froude number, provides an important quantitative measurement of jet characteristics and is shown below.

$$F = \frac{U_o^2}{gD(\rho_a - \rho_o)/\rho_o}$$

where U_o is the jet's discharge velocity, g is the acceleration of gravity, D is the discharge diameter of the jet, ρ_a is the density of the crossflowing ambient and ρ_o is the density of the jet fluid at its point of discharge.

The Gaussian velocity and temperature profiles assumed by most models of buoyant jets are very similar. Velocity behavior is given by:

$$U(r) = U_m \exp(-r^2/B^2)$$

where U_m is the centerline velocity, r is the independent variable and a radial distance from the centerline of the

jet, and B is defined as nominal jet halfwidth. As r approaches B , velocity decays to $(1/e)U_m$ [Ref. 3]. Similarly, temperature behavior is given by:

$$T(r) = T_m \exp(-r^2/\lambda^2 B^2)$$

where T_m is the centerline temperature, r and B are defined the same as above and λ , a spreading ratio, is the inverse of the turbulent Schmidt number (S). S is defined as the ratio of the molecular momentum and mass diffusivities and is equal to ν/D_{AB} where ν is the kinematic viscosity and D_{AB} is the binary mass diffusion coefficient associated with substances A and B [Ref. 4]. Although λ varies inversely with the Froude number, the change is very slight, and in the case where substances A and B are both water, λ is slightly greater than 1. Hirst [Ref. 3] found λ to vary between 1.16 at $F = 0$ to 1.11 at $F = \text{infinity}$. The net effect then, is a more gradual temperature decay than was found with velocity.

Most buoyant jet models consider the entrainment of the ambient fluid into the jet and are based on relevant conservation equations of mass, momentum and energy. In conservation of mass, the downstream change in total mass of the jet is equated to the mass of the entrained fluid. The conservation of momentum must consider both vertical and horizontal contributions. Changes in vertical momentum are equated to the buoyant forces while changes in the horizontal

momentum of the jet are equated to the horizontal momentum of the entrained fluid. The conservation of energy involves energy changes resulting from variations in the ambient temperature as caused by the jet. Hilder [Ref. 1] developed the following governing equations in non-dimensional differential form.

$$\text{CONTINUITY} \quad \frac{d}{ds}(u_m b^2) = 2ab \left[\left| \frac{u_m}{R} - \cos \theta \right| + a_3 R \sin \theta \right]$$

$$\text{HORIZONTAL MOMENTUM} \quad \frac{d}{ds}(u_m^2 b^2 \cos \theta) = 4Rab \left[\left| \frac{u_m}{R} - \cos \theta \right| + a_3 R \sin \theta \right]$$

$$\text{VERTICAL MOMENTUM} \quad \frac{d}{ds}(u_m^2 b^2 \sin \theta) = \left(\frac{\rho_a - \rho_m}{\rho_a - \rho_{mo}} \right) \cdot \frac{2\lambda^2 b^2}{F^2}$$

$$\text{ENERGY} \quad \frac{d}{ds} \left(u_m T \cdot \frac{\lambda^2 b^2}{(\lambda^2 + 1)} \right) = \frac{\Delta t_a}{ds} (u_m b^2)$$

B. FLOW REGIMES

The jet passes through several regimes as it travels from the nozzle through the ambient. The three regions most frequently referred to are shown in Figure 1. They are the zone of flow establishment, the zone of established flow and the far-field zone [Ref. 3]. In the zone of flow establishment, the velocity and turbulence profiles transform from the conditions within the nozzle to a free turbulent flow condition. It is in this region that the jet begins to mix with the ambient fluid; however, the flow is still more

Figure 1. Typical Flow Regions in a Buoyant Jet

strongly influenced by the nozzle discharge conditions than by the ambient. When the turbulent mixing has reached the centerline of the jet, the zone of established flow is said to begin. In this region, the profiles have assumed their free turbulent shapes. Now the flow is governed by the jets' momentum and buoyancy as well as by the condition of the crossflow. The far field zone is defined as that region in which jet momentum is depleted and the jet fluid is convected and diffused by the ambient currents and turbulence.

C. EFFECTS OF CROSSFLOW

At the immediate exit of a cylindrical nozzle, a vertically discharged buoyant jet has a nearly uniform velocity distribution and has the same cross-sectional shape as the nozzle itself. The velocity gradient between the jet and the crossflowing ambient creates longitudinal shear stresses at the jet's sides, a positive pressure region immediately upstream and a negative pressure region immediately downstream of the jet. This results in the deflection of the jet's trajectory in the downstream direction (Figure 2), the creation of counterrotating vortices at the jet's outer edges and the deformation of the original circular cross-sectional shape into the form of a kidney. As the stream-wise axis of the jet approaches the direction of the crossflow, these effects become progressively less pronounced.

Figure 2. Coordinate System for a Buoyant Jet

III. EXPERIMENTAL APPARATUS

A. SYSTEM OVERVIEW

A surplus milling machine was configured with synchronous drive motors interfaced with a microcomputer that automatically positioned its bed. It was used as a three-dimensional positioning platform in the same manner as in the laser Doppler velocimetry work undertaken by Nickodem [Ref. 2]. The milling machine was placed adjacent to a rectangular plexiglass flume through which the crossflowing ambient fluid flowed. A vertical nozzle was installed in the base of the flume to provide the jet. A temperature probe was suspended through an opening in the top of the flume above the nozzle by an arm attached to a base mounted on the milling machine bed as shown in Figure 3. As the probe was automatically traversed through a series of preprogrammed positions across the jet, temperature data was automatically sensed and stored at high speeds by the computer.

B. CROSSFLOW SYSTEM

As illustrated in Figure 4, the crossflow circulation pump took water from the cylindrical 248.8 l (65.7 gal) reservoir shown in Figure 5 and discharged through 5.076 cm (2 in) diameter tubing into a cylindrical flow settling chamber 30.46 cm (12 in) in diameter and 60.91 cm (24 in) tall located within the 60.91 cm $\times$ 60.91 cm $\times$ 88.83 cm

Figure 3. Probe and Traversing Mechanism

Figure 4. Crossflow and Jet Loop Piping Diagram

Figure 5. Flume Circulation and
Jet Loop Pumps

Figure 6. Inlet and Flow
Settling Chambers

(24 in · 24 in · 35 in) inlet chamber shown in Figure 6. The settling chamber was sealed at its bottom so that the water spilled from its top into the inlet chamber through honeycombed flow straighteners to reduce turbulence and evenly disperse the flow. To further reduce turbulence, the flow was broken by another stack of honeycombed flow straighteners and a layer of fiberglass filter material located immediately above the normal operating water level. The flow next entered a 24.4 cm · 32.39 cm · 182.9 cm (9.625 in · 12.75 in · 72 in) flume shown in Figure 7 through a vertical section of the same honeycombed material mentioned above. To avoid inadvertent spillage over the sides of the flume during system start-up, a 5.076 cm (2 in) diameter overflow pipe was located in the inlet chamber. During normal operation, a gate valve in this piping was closed. The flow left the flume through a 7.614 cm (3 in) diameter pipe at its end and re-entered the crossflow circulation pump reservoir. A gate valve located in this piping and shown in Figure 8 was used to regulate the water level and flow velocity in the flume. The optimum adjustment of this valve was determined by trial and error to be closed two turns from its fully open position. Either a globe or ball valve would have been more appropriate for this purpose; however, neither was readily available, so the gate valve was used. The bracket shown at the base of the flume in Figure 8 maintained alignment between the flume and the milling machine. The water

Figure 7. Flume Arrangement

Figure 8. Flume Discharge Piping

in the flume was gradually heated by repetitive circulation through the crossflow pump and by the addition of the heated water from the jet. To maintain a constant temperature crossflow, cooling water from a refrigerated bath shown in Figure 9 was circulated through a coil of 1.269 cm (.5 in) diameter copper tubing located in the flow settling chamber. Also, fresh water was added at the flow settling chamber as an equal amount was drained from the crossflow pump reservoir through a 1.269 cm (.5 in) diameter pipe. Crossflow temperature was monitored by a Type-T thermocouple located in the inlet chamber.

C. JET SYSTEM

In reference to Figures 4 and 5, the jet flow pump circulated water from a rectangular 26.27 l (6.94 gal) reservoir and discharged through 1.26 cm (.5 in) diameter tubing to a 33.0 cm x 50.8 cm x 54.6 cm (13 in x 20 in x 21.5 in) head tank (Figure 10). The amount of flow to the head tank was regulated by a globe valve. Due to a low flow rate to the head tank, water was also recirculated back to the reservoir in order to maintain sufficient flow through the jet pump to prevent overheating it. A constant water level was maintained in the head tank by a stand pipe which allowed overflow back to the reservoir. Sufficient flow into the tank was maintained to make sure that it slightly overflowed continuously. Water drained from the bottom of the head tank through 1.26 cm (.5 in) diameter tubing and passed

Figure 9. Refrigerated Bath

Figure 10. Head Tank

through a rotometer, a .95 cm (.375 in) tubing reducer, a dye injection system (Figure 11), a water heater (Figure 12) consisting of approximately 6.09 m (20 ft) of .95 cm (.375 in) diameter copper tubing coiled in a heated bath and finally a 7.144 cm (.28125 in) nozzle which discharged into the bottom of the flume. Flow was controlled by pinching the tubing between the heater and the nozzle with surgical clamps. Drainage from the crossflow reservoir discussed in Section III.B was used to replenish the jet reservoir. The dye injection system, used in photographing the jet, was located approximately 8.23 m (27 ft) upstream of the nozzle to minimize any disturbance to the jet that it might have caused. The majority of this distance was taken up by the heating coil mentioned above. The vertical distance between the top of the stand pipe in the head tank and the tip of the nozzle in the flume was 2.2 m (86.5 in) which equated to 21.56 KPa (3.127 psig). Jet flow temperature was monitored by a Type-T thermocouple located within the jet flow tubing approximately 1.167 m (46 in) from the nozzle.

D. TEMPERATURE PROBE

Measuring temperatures in a buoyant jet with a thermocouple is intrusive. To reduce the probability of distorting results, steps were taken to minimize the cross-sectional area of the temperature measuring device as seen by the flow of the jet. A .0254 mm (.001 in) diameter Type-E micro-thermocouple was selected. The suspension device for the

Figure 11. Dye Injection System

Figure 12. Jet Heater

microthermocouple had to be rigid and have a small cross-sectional area, for reasons discussed above, as well as be an electrical insulator to prevent interference with the thermocouple performance. A glass annulus approximately 1.45 mm (.057 in) in diameter and 11.27 cm (4.4375 in) in length was chosen. One lead of the thermocouple was threaded through the annulus and the other was glued with a fast drying modelers' glue along the outer surface, allowing the microthermocouple junction to protrude slightly from the tip of the annulus. The leads at the opposite end of the annulus were welded to .0762 mm (.003 in) diameter wire which subsequently was connected to 28 AWG extension wire to the computer. The annulus was mounted as shown in Figure 13. Henceforth, this device will be referred to as the probe.

E. PROBE ACTUATOR ASSEMBLY

The cross sectional area of the probe as seen by the jet was further reduced by orienting the probe tangentially to the trajectory of the jet as shown in Figure 14. This photograph indicated that the probe created no noticeable interference with the jet hydrodynamics. Probe orientation was accomplished by the linkage assembly shown in Figure 15. The fixed end of the probe was hinged to a streamlined tube 23.495 cm (9.25 in) long with a maximum width and depth, as seen by the jet, of 3.175 mm (.125 in) and 6.35 mm (.25 in) respectively. It was rigidly connected to the mounting

Figure 13. Probe Profile

Figure 14. Probe in Jet

Figure 15. Probe Assembly Linkage

bracket as shown in Figure 15 which was connected to the probe arm shown in Figure 3 by a single stud which allowed pivoting of the probe from side-to-side. The stud was also hollowed so that a linkage rod could extend from the hinge assembly through the tube and stud to a stroking pulley which was rotated by a small motor. The hinge assembly and the stroking pulley were spring loaded to reduce hysteresis. As shown in Figures 16 and 17, the 1.5 VDC motor, geared to one rpm, was directly coupled to a potentiometer as well as the drive pulley. The potentiometer was configured in a voltage divider such that the amount of motor rotation, and ultimately the degree of probe deflection, was proportional to the potential difference sensed across the potentiometer. Limit switches were installed at the stroke pulley as shown in Figures 16 and 18 to prevent damage to the linkage assembly due to over-rotation.

F. MICROCOMPUTER INTERFACE

The data collection process consisted of adjusting the probe angle of deflection, traversing the three-dimensional positioning platform and measuring temperature profiles. All of the mechanisms which controlled these events were interfaced to an HP-9826 computer shown in Figure 19 through an HP-6942A multiprogrammer which performed high speed analog-to-digital conversions and ultimately provided control signals to govern relays within the system. Refer to MAIN_T in Appendix B for the microcomputer software which directed this process.

Figure 17. Probe Actuator Motor-Potentiometer Arrangement

Figure 18. Probe Actuator

Figure 19. HP-9826 Microcomputer

1. Probe Angle Adjustment

As discussed in Section III.E, a potentiometer configured as a voltage divider provided probe angle feedback to the computer as shown in Figure 20. The direction of motor rotation was controlled by the computer through Type-MRR1CDL replays connected as shown in Figure 21. When the probe was at a desired position, a 5.0 VDC signal was applied to pins 6L and 6R which allowed both relays to assume the normally closed (NC) positions which opened the power circuit to the motor. When it was desired to rotate the motor clockwise, pin 6R was grounded which resulted in 5.0 VDC applied across the coil in the right-hand relay. This caused the relay to assume its normally open (NO) position resulting in a 1.5 VDC signal at terminal B of the motor causing it to rotate in the clockwise direction. The left-hand relay was activated in a similar manner for counterclockwise rotation. Refer to PROBE_SUBS in Appendix B for probe positioning software.

2. 3-D Positioning Platform Movement

Positioning platform movement was controlled in a manner similar to the probe and was discussed in detail by Nickodem [Ref. 2]. Refer to MTR_SUBS in Appendix B for associated HP-9826 software.

3. Temperature Data Collection

Three thermocouples were monitored in the data collection process. A Type-T thermocouple located in the inlet chamber measured the ambient fluid temperature in the flume,

Figure 20. Computer Bus and Probe Voltage Divider Wiring Diagram

Figure 21. Probe Motor Wiring Diagram

a Type-T thermocouple located in the tubing between the heater and the nozzle measured nozzle temperature and a Type-E microthermocouple in the probe measured the temperature in the jet. The EMF's generated by these thermocouples were amplified by "Omega Omni-Amp IIB" millivolt amplifiers shown in Figure 22 prior to entering the multiprogrammer for analog-to-digital conversion and eventual transformation to temperature readings. Fourth-order least squares coefficients for this conversion were taken from Beckwith [Ref. 5]. Operation of the crossflow circulation pump created sufficient electrical interference to distort the thermocouple signals. This problem was corrected by applying a thin coating of silicon sealant to the Type-T thermocouple junctions and by connecting the crossflow circulation pump casing, the nozzle and the jet tubing in the vicinity of the nozzle thermocouple to a common ground. Because the jet tubing was plastic, it was necessary to manufacture a brass "T" connector as shown in Figure 23 which was grounded and located in close proximity to the thermocouple junction. Refer to T_SUBS in Appendix B for associated software.

Figure 23. Nozzle Thermocouple Grounding Arrangement

IV. EXPERIMENTAL PROCEDURES

A. CALIBRATION

Before the data collection process could begin, the rotometer, the thermocouples, the probe and the positioning platform had to be calibrated. The detailed steps taken are discussed below.

1. Rotometer

With a constant level maintained in the head tank and the jet tubing disconnected from the nozzle and elevated to the same height as the top of the nozzle, five 100 ml samples were drawn through the rotometer and timed to the nearest 0.01 second at each rotometer reading from 10% to 75% in 5% increments. Flowrates and standard deviations in ml/s are shown in Table 1.

2. Thermocouples

Since nozzle and probe temperatures were to be normalized by the ambient temperature, the nozzle and probe thermocouples were calibrated relative to the ambient thermocouple by using the microcomputer program T_CAL in Appendix B. The procedure followed is outlined in the initial comments of the program. Coefficients for first order curve fits were solved by the least squares method with the mainframe programs TCAL and TFIT found in Appendix C.

3. Probe

As the probe assembly was being developed, it was convenient to test its suitability with the probe calibration panel shown in Figure 24. Resistance changes across the potentiometer were recorded for varying degrees of deflection. Analysis of this information led to improved designs from the standpoint of reduced hysteresis and repeatability. The microcomputer program PROBE_CAL in Appendix B was developed to enable calibration of the final design after it was installed in the system as shown in Figures 25 and 26. The calibration procedure is outlined in the preliminary comments of the program.

4. 3-D Positioning Platform

The positioning platform was calibrated in a manner that placed the tip of the probe at desired locations within the flume relative to the tip of the nozzle. Referring to the coordinate system illustrated in Figure 2, the center of the nozzle was defined as (0,0,0) in xyz-coordinates. The following relationships apply to the probe geometry shown in Figure 27:

$$X(\text{real}) = X_0 - R_a \cos \alpha \tan(\pi/4 - \alpha/2)$$

$$Y(\text{real}) = Y_0 + r_p(1 - \cos \gamma) + R_a \cos \alpha$$

$$Z(\text{real}) = Z_0 - r_p \sin \gamma$$

Figure 25. Probe Calibration Panel

Figure 27. Probe Positioning Geometry

(X_0, Y_0, Z_0) was the position of the milling machine bed when the tip of the probe was at position $(0,0,0)$ with $\alpha = 0$ and $\beta = \gamma = 90$ degrees. For calibration, the probe and probe arm were configured with these settings as shown in Figure 28. With measured values of r_p and R_a entered into the microcomputer program MAIN_T, the calibration was accomplished by the program MOTOR_CAL. The step-by-step procedure followed was outlined in the subprogram "SUB Calibrate." As illustrated in figures 3, 27 and 28, the length of R_a could be modified to compensate for adjustments of α and β to positions other than 90 degrees. Decreasing α increased the distance along the Y-axis in which the probe could be positioned. Increments of α and β were scribed on the top of the base and at the tip of the probe arm in Figure 28 to accommodate this change, if desired. The program MAIN_T queried the user for the value of α and assumed $\alpha = \beta$. The calibration software also established position limits to prevent driving the probe into the sides of the flume.

B. PRELIMINARIES

Crossflow velocity was determined by injecting blue food coloring into the flow and timing its travel through a 1.0 m interval. The average of several trials indicated the velocity was .130 m/s (.427 ft/sec) with the flume outlet valve closed two turns from its fully open position.

Figure 28. Probe Arm Positioning for Motor Calibration

Figure 29. Typical Buoyant Jet as Observed with Dye Injected

Photographs of jet profiles as shown in Figure 29 were taken to determine jet trajectory and halfwidths along the streamwise axis. This was done by infecting blue food coloring into the jet flow as discussed in Section III.C. The specific gravity of the food coloring was found to be considerably less than that of water. To eliminate the added buoyant effect this would have had on the jet, a small quantity of alcohol was mixed with the food coloring as suggested by Merzkirch [Ref. 6]. The amount of alcohol added was determined by trial and error. As small quantities were added and mixed, samples were gently placed on the surface of a beaker of water. Pure food coloring laid on the surface and very slowly mixed with the water. As alcohol was added, this buoyant effect grew progressively less and the mixture would settle into the water. The mixture was considered satisfactory when it no longer laid on the surface, but settled to some equilibrium position in the beaker.

Slide photographs of the jets were projected onto large sheets of 3.175 mm (.125 in) grid graph paper and digitized along approximate streamwise axes and half-width trajectories. A scaling factor was determined by equating the projected width of the nozzle to its known outer diameter of 7.9375 mm (.3125 in). The above data was fit to the Michaelis-Monter Equation [Ref. 7] shown below by the least squares method with the mainframe program JETCURV in Appendix C:

$$z = \frac{ay}{b + y}$$

Correlation coefficients close to 1 were consistently obtained. To determine positions within the jet at which to make temperature measurements, five evenly spaced positions per jet flow rate were selected along the streamwise axis in the zone of established flow. Data planes slightly larger than the jet width were centered at these points and oriented perpendicular to the streamwise axis. One hundred data points were selected in a symmetric square matrix with points most densely populated near the center. The planes were identified alphabetically and in consecutive order from "A" to "F", where "A" represented the plane nearest the nozzle. The positions were entered into the microcomputer and stored by plane on a floppy disk by the program LOAD_XYZ in Appendix B. Accompanying each data point was a probe deflection angle used to orient the probe parallel to the path of the jet to minimize interference. This angle was determined by evaluating the first derivatives of the equations developed for the streamwise axis and the half-widths and performing an interpolation based upon the data points' position relative to the two curves.

C. DATA ACQUISITION

The flow systems were placed into operation and the ambient and nozzle temperatures were monitored with the program T_SUBS to evaluate system stability and readiness for data acquisition. The system usually took approximately two hours to come into equilibrium. This could be monitored

by watching the jet nozzle temperature. When conditions were stable, data consisting of two hundred probe, ten ambient and ten nozzle temperature samples per position was collected, one plane at a time, by the program MAIN_T. The following information was stored on a floppy disk for each data point: x, y, and z coordinates; mean probe, nozzle and ambient temperatures and the standard deviation of the probe measurements. The data was transferred to the mainframe computer by using a modem, the microcomputer program SEND_DATA and the mainframe program GRAB.

D. DATA REDUCTION

The raw data was organized into a more usable format by the mainframe program TDATA which also converted the XYZ coordinates into the XSW system shown in Figure 2. The resulting data was selectively sent to the program CONTOUR4 which applied calibration coefficients to the temperature data and normalized it in the following manner:

$$T = \frac{T_p - T_a}{T_n - T_a}$$

where T_p was the jet temperature as measured by the probe, T_a was the ambient fluid temperature and T_n was the temperature of the jet within the nozzle.

Contour plots of this information, generated by the CONTOUR option of the graphics package DISSPLA [Ref. 8], are presented in Figures 30 through 35.

E. RESULTS

The contour plots found in Figures 30 through 35 support the conjectures in Section II.C concerning the effects of the crossflow. Figure 30, a plot of plane A centered on the streamwise axis 46 degrees from horizontal and 7.327 mm (.288 in) downstream of the nozzle shows significant distortion. Figures 31 through 35 show planes A through E sequentially plotted on the same scale in order to observe overall jet behavior. Plane E was located 87.313 mm (3.438 in) downstream of the nozzle and 86 degrees from horizontal. It can be seen that as the jet traveled further downstream, the distorting effect grew progressively less, as expected.

The rate of heat transfer from the jet to the ambient was calculated for each plane utilizing the temperature distribution matrix generated in the program CONTOUR4 in Appendix C and the following relationship:

$$\dot{Q} = \sum_{i=1}^m \sum_{j=1}^n \rho c_p A_{ij} U_{ij} T_{ij}$$

where ρ was the relative density of the jet, A_{ij} was the area of each matrix segment, U_{ij} was the velocity in each segment, c_p was the specific heat of the jet and T_{ij} was the temperature in each segment. Velocity was measured along the streamwise axis by a laser Doppler velocimeter (LDV). It appeared to be nearly constant in the region of the jet observed. The mean and standard deviation was 44.875 mm/s

and 1.8 mm/s respectively. By assuming the Gaussian profile shown in Section II.B, velocity was determined at radii corresponding to each segment in the matrix mentioned above. The rates of heat transfer are shown in Table 2.

V. CONCLUSIONS AND RECOMMENDATIONS

The objective of this thesis was to develop a computer-aided data acquisition system and construct a microthermocouple probe to be used by follow-on students to study temperature distributions in turbulent buoyant jets. Sample data was taken to verify system operability. Based on results, the system performed in a satisfactory manner and will be an invaluable tool for subsequent studies of buoyant jets in a crossflowing ambient.

Data point positions were hand calculated and loaded into the microcomputer with the program LOAD_XYZ. This was an extremely time consuming task and distracted the user from defining more than 100 data points per plane. The system can be greatly improved with the addition of microcomputer software that would automatically determine and load data point positions. Data point population could then be increased with ease which should result in smoother contour plots and more accurate heat transfer calculations.

It was necessary to continuously add fresh water to the crossflow system as an equal amount was drained from it in order to maintain the crossflowing ambient at a constant temperature. This was because the cooling coil located within the flow settling chamber was inadequate to compensate for the heat added to the system by the jet and the

crossflow circulation pump by itself. Although it was possible to maintain the ambient constant within 1.4 C by this method, in the interest of conserving water, it is recommended that either a larger capacity chilled water bath or a cooling system that circulates a refrigerant rather than water be appropriated for this purpose.

APPENDIX A
UNCERTAINTY ANALYSIS

Experimental uncertainty was analyzed in accordance with the guidelines set forth by Holman [Ref. 9]. Uncertainties in the primary measurements, based upon manufacturer specifications and/or the number of significant digits which could be read, follow:

1. Time (rotometer calibration):	.01 s
2. Volume (rotometer calibration):	1.0 ml
3. Rotometer reading:	1.0 percent
4. 3-D positioning platform resolution:	.1524 mm
5. Probe deflection angle resolution:	.5 degrees
6. Thermocouple resolution:	.0099 °C
7. Thermocouple time constant:	.004 s
8. Time (crossflow velocity):	.01 s
9. Length (crossflow velocity):	.05 m

Based on the above, the uncertainty of the flow rate of the jet was estimated to be 1.0 ml/s. Maximum uncertainty in the position of the probe's tip due to the uncertainty in deflection angle was determined to be .983 mm (.0387 in). Combined with the resolution of the positioning platform, the tip of the probe was positioned with an uncertainty of 1.135 mm (.0447 in) in each plane, or with an overall uncertainty of 1.605 mm (.063 in) in three-dimensional

space. Temperature was measured at the approximate rate of 100 samples per second, well within the constraints of the thermocouple time constant. Uncertainty in the temperature measurements were governed by the resolution of the analog-to-digital converter which was .0099 °C. Uncertainty in the crossflow velocity was .00625 m/s (.0205 ft/sec).

940 ! Calibrate the positioners on the
950 ! milling machine movement.
960 ! Onto disk, write out the calibration
970 ! coefficients and the hard boundaries
980 ! that must be observed!
990 ! This file will be called "Motor_coef".
1000 !
1010 ! A. Position the probe volume at the
1020 ! wall of the tip of the nozzle. This
1030 ! position is (0,0,0). All readings
1040 ! will be in inches. Read all three
1050 ! potentiometers. Ask the user for the
1060 ! nozzle outer diameter and compute the
1070 ! zero position. Ask the user for the
1080 ! milling machine readings.
1090 !
1100 ! B. Next, move the bed to some new posi-
1110 ! tion using the override switches.
1120 ! Take readings from the pots and ask
1130 ! for the milling machine readings.
1140 ! Compute the calibration coefficients.
1150 !
1160 ! C. Move the bed to each of the extremes
1170 ! in the X, Y, and Z directions using
1180 ! the override switches and have the
1190 ! user tell the computer when each of
1200 ! these boundaries are hit. Enter each
1210 ! of these onto the disk file.

50
60      SUBPROGRAM T_COUPLE
70
80      by Bill Culbreth
90      19 April 1984
100
110      PURPOSE: This program is designed to
120                read type T or E thermocouples and
130                return the actual temperature to
140                the calling routine.
150
160      Temperature -- Temperature from the
170                thermocouple in degrees F or C from
180                the thermocouple identified by
190                "Choice$".
200      Choice$ -- Thermocouple choice, current-
210                ly: "AMBIENT", "NOZZLE", or "PROBE".
220      Scale$ -- "F" for Fahrenheit or "C" for
230                Celsius, or "H" for histogram in "C".
240      No_readings -- How many readings of the
250                same thermocouple should the routine
260                take?
270      Stdev -- The standard deviation of the
280                temperature for the indicated number
290                of readings in the units given by
300                "Scale$".
310
320
330      1. Open all relays and initialize the
340          A/D converter.
350
360      OUTPUT 723:"CC,1T"

6. CONTOUR4

```

C
C
C      CONTOUR4
C
C      PURPOSE: THIS PROGRAM IS DESIGNED TO DISPLAY BUOYANT JET
C                TEMPERATURE DATA USING A CONTOUR PLOTTING PACKAGE
C                AVAILABLE WITH DISPLA. THE FOLLOWING RAW DATA IS
C                READ FROM A DISK FILE: PROBE POSITIONS IN XYZ
C                COORDINATES RELATIVE TO THE NOZZLE TIP, AMBIENT
C                TEMPERATURE, PROBE TEMPERATURE AND NOZZLE TEMPERATURE.
C                THE PROBE AND NOZZLE TEMPERATURES ARE TRANSFORMED
C                BY CALIBRATION COEFFICIENTS AND NORMALIZED WRT AMBIENT
C                TEMPERATURE. THE XYZ COORDINATES ARE CONVERTED TO
C                XSA COORDINATES RELATIVE TO THE INTERSECTION OF THE
C                DATA PLANE WITH THE CENTERLINE TRAJECTORY OF THE JET
C                (THE S-AXIS IS TANGENT TO THE TRAJECTORY). THIS
C                PROGRAM ALSO COMPUTES THE RATE OF HEAT TRANSFER FROM
C                THE JET TO THE AMBIENT.
C
C      NOTE: THE FOLLOWING VALUES MUST BE INSERTED AS THE
C            FIRST LINE OF DATA IN FREE FORMAT: THE TOTAL NUMBER
C            OF DATA POINTS (NITEMS), THE ACUTE ANGLE BETWEEN
C            THE DATA PLANE AND HORIZONTAL (THETA) AND THE VERTICAL
C            DISTANCE BETWEEN THE Z-AXIS AND THE INTERSECTION
