20. ABSTRACT (Continue on reverse side if necessary and identify by block number) / Airblast attenuation through entranceways into structural components was in- vestigated in a small-scale explosive test series during 1983. Thirty tests were performed with steel constructed models of square cross-section tunnels in configurations typically found in field fortifications and personnel shelters. Model structures included tunnels with 15 cm and 30 cm entrance widths and 42 and 17 tunnel diameters long, respectively, blast shields in front of tunnel entrances, and abrupt expansions in entranceways. Spherical charges ranging (Continued)

SECURITY CLASSIFICATION OF THIS PAGE(When Data Entered)

20. ABSTRACT (Continued).

from 113 to 907 grams were detonated outside the tunnel entrances in end-on and side-on geometries. Airblast measurements were made at various positions along the tunnel walls.

Pressure-time histories with corresponding integrated impulse histories and tabulated peak values are presented. Plots of pressure versus scaled distance are presented, along with comparisons of data from previous tests of the airblast penetration program which investigated airblast attenuation in tunnels of round cross-section.

As the distance from the blast source increases, the pressure and impulse values decrease. The data from the previous tests are compared with the data from the current tests. The results show that the airblast attenuation in tunnels of round cross-section is similar to that in tunnels of rectangular cross-section.

PREFACE

This investigation was sponsored jointly by the Office, Chief of Engineers (OCE), U. S. Army, and by the Air Force Engineering and Services Center, Tyndall AFB, U. S. Air Force. The work was performed under OCE R&D Project 4A161102AT22, Task area B0, Work Unit 003.

The investigation was conducted during the period July 1983 to September 1983 by personnel of the Structures Laboratory (SL), U. S. Army Engineer Waterways Experiment Station (WES), Vicksburg, MS. The field tests were conducted by C. D. Little, Jr., R. Walters, S. B. Price, and J. Stout of the Explosion Effects Division (EED).

L. T. Watson and L. Sadler of the WES Instrumentation Services Division (ISD) provided field instrumentation support and instrument calibration, respectively.

Data processing was performed by J. T. Brogan and D. W. McAlpin, EED.

The investigation was under the general supervision of J. W. Brown, former Chief, EED, J. D. Day, Chief, EED, and B. Mather, Chief, SL. COL Tilford C. Creel, CE, was Commander and Director and F. R. Brown was Technical Director of WES during the investigation.

AIRBLAST ATTENUATION IN ENTRANCEWAYS AND OTHER TYPICAL COMPONENTS
OF STRUCTURES: SMALL-SCALE TESTS DATA REPORT 2

CHAPTER 1
INTRODUCTION

1.1 BACKGROUND

Many permanent shelters and field fortifications have openings into which airblast from near-miss conventional warhead explosions may propagate to produce damage and injury to the interior. A large amount of research has been conducted for long duration pulses simulating nuclear detonations (Reference 1). But before this test program only a small amount of information was available for high pressure, extremely short duration pulses produced by conventional weapons. Experimental data in this area are limited to a few shock tube tests (Reference 2), and limited small-scale high explosive tests (References 3 and 4). Important differences between these results and the nuclear blast simulations have been noted, and calculational techniques developed for the long duration pulses have often had poor success in predicting the attenuation of high pressure, short duration pulses.

This investigation was designed to obtain information needed to determine fundamental characteristics of short duration shock penetration into structures through openings.

1.2 OBJECTIVE

The objective of this investigation was to develop an experimental data base for the airblast produced by conventional high explosive detonations which intrudes into structures through air entrainment systems, doors and other openings. This information will provide an experimental basis for the development

of airblast prediction methods for the selection of blast doors and blast valves and the design of the geometrical configuration of personnel and air entrainment entranceways to suppress blast.

The objective of this report is to present the experimental data obtained in the small-scale explosive test program and a brief and limited analysis of some basic observations.

This report describes the second phase of the experimental effort consisting of a comprehensive small-scale explosive test program conducted in the summer of 1983.

1.3 PURPOSE

The purpose of the 1983 series of the investigation was to enhance the existing data base by providing test data from square tunnels, many tunnel diameters in length. The results will be useful in correlating airblast attenuation in long square tunnels with that of long round tunnels (investigated in 1981 and 1982 series). The effects of abrupt expansions in entranceways and reflections off entrance shields from side-on bursts were also investigated.

CHAPTER 2

EXPERIMENTAL PLAN

2.1 TEST PROGRAM

The experimental program consisted of 30 spherical charges, ranging from 113 to 907 g of Composition C-4 explosive, detonated outside the entrance of tunnels of square cross-section. The model structures consisted of a 30 cm square tunnel 17 tunnel diameters in length and a 15 cm square tunnel 42 tunnel diameters in length. Seven of the 22 tests of the 30 cm square tunnel included a blast shield placed in front of the tunnel entrance. Side-on bursts were used with this configuration to access the effects of reflected blast waves from the entrance shield which intrude into the tunnel opening. Seven of the 30 cm square tunnel tests included a 15 cm square contraction insert which was placed in the entrance of the 30 cm tunnel. The purpose of the insert was to provide an abrupt expansion from a small tunnel to a larger tunnel. End-on burst configurations were used for all tests except for the side-on bursts used with the entrance shield configurations. Details of test parameters are given in Table 2.1.

The test structures were fabricated from steel plate and heavy wall (0.95 cm thickness) steel tubing. Pressure transducers were mounted from the outside of the tunnel so that the sensing surface was flush with the inside wall to obtain side-on blast measurements.

The tests were performed at the Waterways Experiment Station Big Black Test Site near Vicksburg, MS.

2.2 STRUCTURE DESCRIPTION

Shots 1-15 of the 1983 series used a 30 cm square tunnel that was

5.18 meters (17 feet) in length (Figure 2.1). Figure 2.2 illustrates the dimensions and gage locations of the tunnel. Shots 3, 5-8, 14, and 15 included a 0.6 m x 0.6 m x 1.27 cm (2 ft x 2 ft x 1/2 in.) entrance shield placed 0.3 and 0.6 meters (1 and 2 feet) in front of the tunnel entrance (Figure 2.3). Entrance shield stand-off distances are listed in Table 2.1.

Shots 16-22 used the same tunnel as Shots 1-15 with the addition of a square tunnel contraction insert (Figure 2.4). The insert reduced the tunnel entrance from 30 cm to 15 cm for a distance of 30 cm and then abruptly returned to the 30 cm square cross-section. Figure 2.5 shows the tunnel, insert, and gage locations for Shots 16-22.

Shots 23-30 used a 15 cm square tunnel that was 6.4 meters (21 feet) in length (Figure 2.6). The tunnel was used to determine the adequacy of scaling routines between the 15 cm and 30 cm tunnels. Dimensions and gage locations are shown in Figure 2.7.

2.3 INSTRUMENTATION AND DATA PROCESSING

2.3.1 Transducers. Airblast overpressures for the 1983 series of tests were measured with Kulite HKS-375 pressure sensors in ranges from 3.45 to 34.5 MPa (500 to 5,000 psi) with natural frequencies of 350 to 675 kHz, respectively, and Kulite XT-190 pressure sensors in ranges from 0.69 to 1.38 MPa (100 to 200 psi) and with natural frequencies of 160 to 200 kHz, respectively.

The transducers were placed in specially designed mounts to reduce vibration and noise caused by shock waves traveling down the tunnel walls. The mount shown in Figure 2.8 was used in locations where high pressure, multiple peak shocks occur, such as near the tunnel entrance. This mount consisted of an aluminum casing and a solid nylon insert. In areas of lower pressure, smooth peaked shocks the mount shown in Figure 2.9 was used. It consisted of

an aluminum case and a nylon insert with a RTV silicon rubber annulus between the aluminum and nylon. Figure 2.10 shows the gage mount adapter for the XT 190 transducers. The transducer/mount assembly was mounted in the tunnel wall flush with the inside surface.

The gages were connected to a junction box approximately 30 meters (100 feet) away with large Beldon 4 conductor shielded cable. The junction box was connected to the recording system with approximately 45 meters (150 feet) of twenty twisted pair, individually shielded cable.

2.3.2 Recording System. The analog signals for the 1983 series tests were recorded using a Sangamo Sabre V 32-track FM wide band Group I magnetic tape recorder with a flat frequency response from dc to 80 kHz. Signals were conditioned with WES developed amplifiers with flat frequency response from dc to 100 kHz.

2.3.3 Data Processing. The analog data signals were converted to digital format using the WES high-speed analog-to-digital converter. All channels were digitized at a rate of 500 kHz. Baseline corrections were applied when necessary to produce zero impulse at shock front arrival.

2.4 TEST PARAMETERS

Composition C-4, a military high explosive, was used for all tests. Most charges were detonated in an end-on position in front of the entrance. Side-on bursts were also used with the entrance shield configurations. Figure 2.11 illustrates the notation used to describe the charge location. Explosive weight, charge location, and entrance shield stand-off distances for each test are shown in Table 2.1. Other information such as shot date, time, and air temperature are listed in Table 2.2.

CHAPTER 3

RESULTS

3.1 WAVEFORMS AND TABULATED DATA

The measured pressure-time histories and corresponding impulse-time histories for the 1983 series tests are given in Appendix A. Information found in the waveform label includes shot number, tape channel number, measurement number, test series title, test component, digitizing rate, and processing date.

Appendix B contains the tabulated parameters illustrated in Figure 3.1 for each test. It should be noted that the impulse listed for the second pulse is the total impulse and not the increase in impulse due to the second pulse.

3.2 OVERVIEW OF DATA

In general, there was a high percentage of data recovery for all tests of the 1983 series. With the exception of Test 12, approximately 80 to 90 percent of the data was recorded in an useable form. No data was recovered from Test 12 due to instrumentation difficulties.

Waveform characteristics observed for this series were very similar to those observed for the 1981 and 1982 series. Waveforms near the tunnel entrance indicate a complex pattern of reflections and diffractions which result in high peaked, short duration pulses, many which contain two peaks. This phenomena appears to be a function of the curvature of the shock front at the entrance of the tunnel. For a given entrance pressure level, smaller charges near the entrance tend to produce this phenomena more than larger charges which are located at a greater radius from the tunnel entrance.

As the airblast shock front attenuates down the tunnel, the sharp-peaked

pulses approach a more stable, uniform condition. Observations from all series tests of the investigation show this stable condition to occur approximately 5 to 8 tunnel diameters from the tunnel entrance. Charges located off center of the tunnel entrance can increase the number of tunnel diameters required for stabilization from test to test. Airblast records at and beyond this stabilization point are much more consistent than records near the tunnel entrance.

The reflected pulse from the end of the tunnel can be observed easily from the latter waveforms of each test. The reflected pulses considerably increase the total impulse observed in the end of the tunnel.

Peak pressure values from the waveforms are overdriven in many cases by a front-end spike caused by gage overshoot. Gage overshoot occurs when the gage is excited by shock front frequencies near its resonant frequency. The peak pressure values tabulated in Appendix B are the author's best attempt at compensating for gage overshoot, and are subject to reexamination.

3.3 COMPARISON OF SQUARE TUNNEL DATA TO ROUND TUNNEL DATA

Comparison of data from square tunnel tests with data from round tunnel tests for similar yields and nominal entrance pressures requires use of a scaling parameter that will establish similitude between the different entrance geometries. The concept of an effective diameter was introduced during the 1981 and 1982 series, and was proposed as equal to $\sqrt{A}$, where A is the cross-sectional area of the tunnel opening. The use of $\sqrt{A}$ as a scaling factor yields the dimensionless parameter $X/\sqrt{A}$, where X is the distance down the tunnel from the entranceway.

Figures 3.2-3.6 illustrate the comparison of peak pressure data from the 30 cm diameter round tunnel tests of the 1982 series with peak pressure data

from the 30 cm square tunnel tests of 1983. Pressures are plotted versus scaled distance, $X/\sqrt{A}$, for several yields (W) and entrance pressures (P_0). The plots indicate reasonable agreement in peak pressure at large scaled distances, where at small scaled distances the data scatter broadens due to uncertainties of the near entrance airblast peaks. However, a general trend of peak pressure attenuation with distance down the tunnel can be determined from the plots. An interesting variation in the two data sets is that peak pressures near the entranceway for the square tunnel tests tend to be higher than near entrance pressures for the round tunnel tests.

As an alternative to $\sqrt{A}$, the diagonal $\sqrt{B^2+B^2}$ was used as the geometrical scaling parameter for the square tunnel data, where B is the width of the entrance. Figures 3.7-3.11 illustrate the comparison of peak pressure data from square tunnels, scaled by $\sqrt{B^2+B^2}$, with round tunnel pressure data, scaled by $\sqrt{A}$. The data tend to agree better when scaled by this method, especially at large scaled distances, although near entrance pressures are still widely scattered.

3.4 COMPARISON OF 30 cm AND 15 cm SQUARE TUNNEL DATA

Cube-root scaling indicates that similitude should exist between the 30 cm and 15 cm tunnels for charge weights of 907 g and 113 g, respectively, at a given entrance pressure. All linear dimensions and times should scale by the factor $\left(\frac{907}{113}\right)^{1/3} = 2$, and peak pressure values should remain the same for similar scaled distances. Figures 3.12-3.14 illustrate the comparison of peak pressure data for the 30 cm and 15 cm square tunnels as a function of scaled distance X/B . Again, data agree well at large values of X/B , but tend to scatter significantly at small values of X/B . Use of the diagonal $\sqrt{B^2+B^2}$ as a scaling parameter would not change the relationship since the parameter for

both tunnels would differ by the factor $\sqrt{2}$.

Figure 3.15 shows the relationship of peak pressure data from the 15 cm square tunnel, $W = 113$ g, with that of the 30 cm round tunnel test from 1982, $W = 907$ g. Scaled distance is shown as $X / \sqrt{B^2 + B^2}$ for the square tunnel and $X / \sqrt{A}$ for the round tunnel.

3.5 EFFECTS OF ENTRANCE SHIELD AND ABRUPT EXPANSION

The effects of the entrance shield on the penetrating airblast wave can best be observed from the individual waveforms for each test. In general, the reflected wave from the entrance shield arrives shortly after the initial pulse, with amplitude at or near that of the initial pulse.

The effects of the abrupt expansion entranceway on airblast penetration are best explained from the individual waveforms, also. Waveforms from measurement locations immediately after the expansion indicate a complex pattern of peaks and reflections similar to those observed in near entrance waveforms. Several tunnel diameters from the expansion, the waveforms tend to stabilize and attenuate with distance at a higher rate than airblast in the regular, non-expansion tunnels of equal width. This is illustrated in Figures 3.16-3.19 for several entrance pressures. Peak pressures are plotted versus scaled distance X/B . The reduction in pressure at large scaled distances would appear to be a result of energy dissipation by the expansion.

CHAPTER 4

CONCLUSIONS

Conclusions developed from the investigation results are as follows:

1. Airblast shock fronts immediately following entranceways and abrupt expansions in tunnel diameter are complex due to reflections and diffractions. Peaks tend to stabilize at 5 to 8 tunnel diameters from the entrance.
2. Square tunnel peak pressure data tend to agree with $\sqrt{A}$ scaled round tunnel peak pressure data better when scaled by the cross-section diagonal $\sqrt{B^2+B^2}$ than when scaled by $\sqrt{A}$ for a given entrance pressure, charge weight, and $D = B$. Pressure values at large scaled distances from the entrance are more consistent and attenuation trends are readily determined.
3. Airblast shocks reflected from entrance shields for side-on detonations tend to further complicate the blast pattern near the entrance with peaks of amplitude at or near that of the initial pulses.
4. Airblast attenuation rates following abrupt expansions from small to large tunnels tend to be greater than rates observed for tunnels of similar large dimensions but without expansions.
