1.0 INTRODUCTION

The following report presents the results of Task 1 of the open-end contract for Engineering Analysis of Ocean Engineering Projects for the Chesapeake Division, Naval Facilities Engineering Command.

This study has been conducted by Brian Watt Associates, Inc. (BWA) of Houston, Texas, and was performed under contract N62477-83-D-0165. It represents an effort of approximately 13 man-weeks. The study was performed as BWA Project No. 210.

1.1 Objectives

The goal of this task is to determine the steady-state dynamic mooring forces for a three-leg semisubmersible buoy, moored in water depths ranging from 100 to 400 feet, and being subjected to the survival wind, current, and wave for the site. The dynamic response of the moored semisubmersible to the survival environment will be simulated using Computer-Aided Design techniques.

1.2 Scope of Work

The scope of work as defined by the Department of Navy was as follows:

- Computer simulation of the dynamic response of the moored semisubmersible for the survival environment at water depths of 400, 250, 150 and 100 feet.
- Design of a mooring system for each water depth. The mooring will be composed of three equal lengths of ABS grade 2 stud link chain. This includes specifying the location of the mooring anchors, the length of the mooring chain, and the size of the mooring chain.
- The mooring will be designed such that the angle formed by the mooring leg, the anchor, and the ocean bottom does not exceed zero degrees and that the maximum tension does not

exceed 35 percent (± 5 percent) of the chain's proof load at any time during the simulation.

- The mooring will be orientated such that one mooring leg will be required to resist all environmentally applied loads.
- The ballasting of the semisubmersible will be adjusted to compensate for the vertical load on the semisubmersible from the mooring legs before performing the dynamic simulation. The dynamic simulation will be continued until the steady-state response can be determined.
- The computer model used must be able to simulate the rigid body motions of the semisubmersible as function of time when subjected to the following external forces:
 1. Hydrodynamic loading on the submerged portion of the structure due to a series of nonlinear near-breaking waves.
 2. Hydrodynamic loading on the submerged portion of the structure due to a uniform current.
 3. Aerodynamic loading on the exposed portion of the structure due to a uniform wind.
 4. Concentrated loading on the structure due to the nonlinear catenary behavior of the three mooring legs.
- The computer model used does not have to be able to simulate environmental loading on the mooring chains, the internal stresses or deflections of the semisubmersible's structural components, or the dragging of the mooring leg anchors when overloaded.

1.3

Government Furnished Information

The following information was provided by the government in performance of this task:

1. An engineering drawing of the semisubmersible. These have been included in this report as Figures 1.1, 1.2 and 1.3.
2. Table 1.1 gives the survival wind, current and wave for each of the four water depths as specified by the government.

2.0 ANALYSIS AND MODEL DETAILS

This section discusses the software used for this task, the details of the computer model, the stream function analysis and the mooring system design procedure.

2.1 BWA Software

The main program used for the simulation, titled SEMI, is a FORTRAN code developed by BWA. This program simulates the motions of tension leg platforms and semisubmersibles in the time domain.

The program SEMI has the following capabilities:

- Wind loading
- Current loading
- Airy wave loading
- Stream Function wave loading
- Catenary moorings
- Tension leg moorings

In addition, the following software has been used as part of the design cycle.

FREQ: A frequency domain program for motion analysis of tension leg and catenary moored semisubmersibles. The program uses Airy wave theory, iterates for a best fit linearizing of the viscous damping and conducts eigenvalue, eigenvector analysis.

DAMS: A program for the design and analysis of single and multi-component mooring systems. Clump weights or buoys can be placed on the mooring lines. Restoring forces on the vessel, high line tension and vessel excursion are printed out.

Apart from the above software which has been developed by BWA, a finite element package ANSYS was run to obtain the system mass, radii of gyration and center of gravity.

2.2 Analysis Methodology

The analysis methodology consisted of iterating in a design loop until a workable system was achieved. The design loop incorporated the evaluation of the moorings, and the evaluation of the entire system in both the frequency domain and the time domain. This simulation cycle is shown in Figure 2.1; related software is listed in Table 2.1.

The analysis began with the estimation of the mean quasi static forces due to wind, wave and current loading. This estimation was made using a time domain analysis with the semi moored by tension legs as shown in Figure 2.2. The extreme length of the tension legs limited out-of-plane forces.

Once the mean forces were known, the magnitude of the first order motions was assumed. The mooring program DAMS then evaluated the proposed mooring systems. After a satisfactory mooring system was found, the required ballast for the operating draft was calculated. The finite element program ANSYS was used to determine the vessel CG and radii of gyration.

A frequency domain analysis was made to determine the mooring loads, and the oscillatory wave forces and motions. Any refinements to the mooring system were made at this point.

After all modifications were completed, the system was analyzed in the time domain. The results of the time domain analysis determined the acceptability of the system.

No effort has been made here to optimize the mooring system. Based on these results a further refinement could be undertaken and additional time domain analyses performed.

2.3 Model Generation

The model generation consisted of defining the semisubmersible by a set of nodes and elements. Each node point is defined by its X, Y, and Z coordinates in three dimensional space. Each element is described by its nodal end

points, its equivalent circular diameter, and its drag and added mass coefficients.

The fluid model generated for this analysis contained 219 elements. The elements were grouped as shown below:

<u>Item</u>	<u>Quantity</u>	<u>No. of Elements</u>
Pontoons	3	3 x 30
Columns	3	3 x 22
Lower Braces	6	6 x 5
Upper Braces	3	3 x 5
Deck Supports	3	3 x 5
Triangular Dampers	3	3 x 1
		219

Plots of the fluid model are shown in Figures 2.3 through 2.9.

The mooring system was attached at a point 12 ft above the bottom of each column. Figure 2.10 shows a plan view of the semisubmersible and the coordinate system adopted. The origin was 27 ft above the bottom and Z is positive upwards.

2.4

Element Size Considerations

In order to properly model the semisubmersible the element sizes must be small enough to avoid numerically induced errors during the solution. There are two criteria for determining the size of major elements exposed to fluid loadings. First, the element length should be less than 10% of the wave length, about 70 feet in this case. Second, a member should be divided into at least twenty elements to enable the proper calculation of inertias and other moment like quantities.

For this particular model, the major elements were divided much finer than required to insure the accurate attainment of moment and inertia quantities.

2.5 Added Mass and Drag Coefficients

The solution technique requires an added mass coefficient and a drag coefficient for flow normal to the element axis and for the exposed ends of the element.

There are two instances when the end of an element must be considered as exposed. The first and most obvious is when the end really is exposed. The second instance occurs at a connection (column to pontoon) where, for pressure equilibrium, a nonexposed end must be input as exposed.

The following values for the drag and added mass coefficients were used:

<u>Item</u>	<u>C_D</u>	<u>C_A</u>	<u>C_D</u>	<u>C_A</u>
	<u>Normal</u>	<u>Normal</u>	<u>End</u>	<u>End</u>
Cylinders	.62	.90	0.4	1.0
Triangles	0.0	0.0	2.0	2.83

The following reference was used in obtaining these values "Mechanics of Wave Forces on Offshore Structures, Turgut Sarpkaya & Michael Isaacson, Van Nostrand Reinhold Company." Figures 3.20 and 3.21 from this reference give the variation of C_D and C_A and have been included as Figure 2.11 in this report. The values of Reynolds number and Keulegan-Carpenter number required to use these figures are shown below:

<u>Item</u>	<u>R_e</u>	<u>K</u>	<u>C_d</u>	<u>C_m</u>	<u>C_a</u>
Pontoons	1.93 x 10 ⁻⁵	90.93	0.62	1.90	0.90
Columns and Braces	2.09 x 10 ⁻⁵	84.00	0.62	1.90	0.90

The coefficients for the triangular dampers were obtained by direct computation.

2.6 ANSYS Modeling

The basic fluid model of the semisubmersible was input into the finite element program ANSYS. This step was necessary to compute the system mass, center of gravity, and radii of gyration.

The ANSYS model differed from the fluid model in that it required dummy elements to connect the members of the fluid model.

The ANSYS element used to represent the structural members of the semisubmersible was the 3-D pipe element, STIF42. The appropriate values for Young's Modulus, Poisson's ratio, density, diameter and thickness were input. To model the ballast water, the STIF42 element was used again. The wall thickness was set equal to the radius, Young's Modulus was set equal to 1, and Poisson's ratio was set equal to zero.

The results from ANSYS giving the centers of gravity and the radii of gyration are shown in Table 2.2

2.7 Stream Function Analysis

A stream function analysis was performed for the four design cases to obtain vertical and horizontal velocities, accelerations, and pressures. This data is output to a binary file which is read as input to the frequency and time domain programs.

The governing equation for stream function modeling is the Laplace equation. The formulation satisfies kinematic boundary conditions at the bottom and free surface, and the dynamic free surface boundary condition. The water particle kinematics are corrected by a vector addition of the current (Ref.: Dalrymple, R. A., "A Finite Amplitude Wave on a Linear Shear Current," J. Geophysical Research, Vol. 79, pp. 4498-4504, 1974). The bottom and surface currents are specified and a linear interpolation is undertaken. As the wave water particle velocities are corrected for the current, the external imposed current velocity for drag computation in the time domain analysis has been set to zero.

The stream function program used for this analysis was developed at Coastal and Offshore Inc. Input requirements include: wave height, wave period, water depth, bottom and surface currents, the order of the problem, number of computational points over 1/2 the wave, maximum number of solution iterations.

The actual input for the four cases is shown in Table 2.3.

2.8 Aerodynamic Loading

The wind loading was estimated based on section 3.5.2 of the "ABS Rules for Building and Classing Mobile Offshore Drilling Units - 1980". The total estimated wind force was 40 Kips acting at 29.4 ft above waterline. Table 2.4 gives the details of the computation and Figure 2.12 shows the semisubmersible projected area used in the calculations.

2.9 Mooring System

The mooring systems used in this study to restrain the semisubmersible were conventional, single-component spread moorings. The basic catenary relationships used for mooring system design are shown in Figure 2.13.

Table 2.5 gives the pertinent properties for various sizes of chain. The maximum chain size allowed was limited to 6 in. This is the largest size commercially produced at the present time without the need for extensive expansion of manufacturing facilities.

Figure 2.14 shows the relationship between scope and water depth used in this study. The scope-water depth curve is nonlinear and corresponds to a constant line length of 2,000 ft.

The coefficient of bottom friction used throughout the study was 0.80. The design of the mooring system at each depth followed the same general procedure:

- (1) Estimate the mean quasi-static force due to wind, wave, and current and the magnitude of 1st order motions using a time domain analysis of the semimoored by tension legs.
- (2) Estimate a starting anchor location based on the line length and water depth (see Figure 2.15).
- (3) Perform a series of mooring analysis varying the chain size. Evaluate systems with respect to high line tension and anchor forces when subjected to forces and motions established in Item 1 (see Table 2.6).
- (4) Select the candidate system based on a review of the results.
- (5) Perform another series of runs, this time varying the anchor location. Evaluate the system with respect to high line tension and anchor forces when subjected to the forces and motions established in Item 1 (see Table 2.7). Select final anchor location.
- (6) Adjust ballasting of semi to account for the vertical load arising from the vertical component of mooring line tension and calculate new CG and radii of gyration using ANSYS program.
- (7) Perform a frequency domain analysis of the trial mooring system to determine natural periods, R.A.O.'s, and phase angles of the system, and to obtain an estimate of the maximum line tensions and anchor loads.
- (8) Revise system based on results of frequency domain analysis, if required.

-11-

- (9) Perform time domain analysis of system.
- (10) Review time domain results to determine system acceptability/rejection.

3.0**RESULTS**

Appendix A to this report contains the frequency domain results and time history plots for each of the design cases.

Table 3.1 gives the parameters for each of the four design cases.

A time step of 0.25 seconds was selected in the time domain simulation. The simulation was carried until steady state was achieved. This corresponds to 400 time steps with a total span of 100 seconds.

The maximum chain size was limited to 6 in. This limit was based on the maximum chain size commercially available from present installations. It was felt that the economics of the problem would not permit any special arrangements for larger chain sizes.

A summary of the results from the frequency domain and time domain are included here.

Table 3.2 gives the results from the frequency domain analysis. The important quantities in this table are the natural periods, response amplitude operators and phase angle in surge, heave, and pitch.

Summary results from the time domain simulation are given in Tables 3.3 through 3.6. The results from this simulation are:

<u>Water Depth</u>	<u>Mooring Chain</u>	<u>Peak Tension (% Proof Read)</u>
412 ft	5 in.	30.84
262 ft	5 in.	31.26
162 ft	6 in.	59.8
112 ft	6 in.	114.8

Figures 3.1, 3.2, and 3.3 give the mooring system characteristics for water depths of 412 ft, 262 ft, and 162 ft. Figure 3.4 gives the variation of the peak horizontal dynamic force against water depth.

4.0

CONCLUSIONS & RECOMMENDATIONS

Based on the preliminary study conducted here, a feasible mooring system, that satisfies all the design criteria defined by the U.S. Navy, has been designed for water depths of 400 ft and 250 ft. The designed mooring system consists of a 5 in. diameter, Grade 2 stud link chain. The length of chain was 2,000 ft for all depths.

No effort has been made under this task to optimize or refine the mooring system. Based on these results, the conclusion is that a 4½ in. diameter chain could be used. Also, the length of chain needs to be optimized and can be reduced in most cases.

All the evaluation in this task was for a survival environment. The response of the system to a design environment with operational constraints also needs to be examined.

A feasible solution was not found for the 150 ft and 100 ft depth. For the 150 ft depth the peak line tension is 59.8% with a 6 in. diameter chain. It is our opinion that an optimization exercise may yield a workable solution. For the 100 ft depth, the peak line tension is 114.8%.

The coupled response of surge, heave, and pitch plays a dominant role in the behavior of the mooring system. At water depths of 400 and 250 ft, the maximum surge displacement is coupled with a negative heave (downwards) and a positive pitch. This results in a slackening of the most loaded line and, thereby, reducing the tension to acceptable levels. At the 150 ft water depth, the maximum surge displacement is coupled with zero heave and a positive pitch. At the 100 ft water depth, the maximum surge displacement is coupled with a positive heave (upwards) and a sharp variation in the pitch response from negative 22 degrees to a positive 9 degrees within a very narrow band. The net result is to make the mooring chain taut, causing high line tensions.

In our opinion, further evaluation of the system needs to be conducted at the 150 ft water depth. A more thorough time domain simulation with irregular sea states, to alleviate the strong dependence on a particular wave frequency and the resulting phase relationship, is recommended to prove the system performance.
