ABSTRACT

★
This report contains data from first time testing of dissected Minuteman II Stage II motor S/N 0022123 assigned to the Reentry System Launch Program (RSLP). No statistical inferences were determined with only one set of data, except for hardness, where humidified and non-humidified specimens were tested.

Data have been overlayed on multi-motor regression plots for visual reference only. Plots have been made to show differences between different blocks and slices of propellant within the same motor used for mini-thin tensile testing.

Visual observation indicates this motor resembles motor S/N 0022135 more closely than any of the previously tested dissected motors.

GLOSSARY OF ABBREVIATIONS AND TERMS

Aging Trend	(Refer to Figure 3 or statistical analysis) A change in properties or performance resulting from aging of material or component
ANX	Outer propellant, ANP-2862
ANY	Inner Propellant, ANP-2864
ASPC	Aerojet Strategic Propulsion Company
Bi-Propellant	Equal sections of ANP-2862 and ANP-2864 in one specimen
CSA	Cross Sectional Area
DB	Dogbone
Degradation	Gradual deterioration of properties or performance
E	Modulus (psi), defined as the slope of the line drawn tangent to the initial linear portion of the curve
EB	End bonded
EGL	Effective Gage Length
e_m	Strain at Maximum Stress (in/in)
e_r	Strain at Rupture (in/in)
"F" ratio	The ratio of the variance accounted for by the regression function to the random unexplained variance. The regression function having the most significant "F" ratio is used for plotting data. The ratio is also used in detecting significant changes in random variation between succeeding time points.
JANNAF	Joint Army, Navy, NASA, Air Force Committee
MAQCP	Propellant Laboratory at OO-ALC
OO-ALC	Ogden Air Logistics Center
Regression	The general form of the regression equation is $Y = a + bX$
Regression Line	Line representing mean test values with respect to time
S_b	Standard error of estimate of the regression coefficient
S_e or $S_{Y.X}$	Standard deviation of the data about the regression line
S_m	Maximum Stress (psi)

GLOSSARY OF TERMS AND ABBREVIATIONS (cont)

S_r	Stress at Rupture (psi)
Standard Deviation (S_y)	Square root of variance
Strain Rate	Crosshead speed divided by the EGL
't' Test	A statistical test used to detect significant differences between a measured parameter and an expected value of the parameter (determines if regression slope differs from zero at the 95% confidence level).
Variance	The sum of squares of deviations of the test results from the mean of the series after division by one less than the total number of test results
3 Sigma Band	The area between the upper and lower 3 sigma limit. It can be expected that 99.73% of the inventory represented by the test samples would fall within this range assuming that the population is normally distributed
90-90 Band	It can be stated with 90% confidence that 90% of the inventory represented by the test samples would fall within this range assuming that the population is normally distributed

INTRODUCTION

PURPOSE: The purpose of this program is to continue surveillance testing of Minuteman Reentry System Launch Program Stage II propellant. This surveillance will elucidate the aging characteristics of the propellant and, using statistical trends derived from laboratory testing, will help to establish the service life expectancy of similar motors in the inventory.

BACKGROUND: Surveillance testing was initiated in 1963 on cartons of propellant cast from the same propellant used in motor manufacture.

In 1971, all laboratory prepared insulation material and case-to-propellant bond specimens were destroyed in a conditioning chamber malfunction. The number of cartons of propellant was also near depletion, which would have terminated the OO-ALC Surveillance Program.

A force modernization program made available some older Minuteman I Stage II motors. In 1973, three of these motors were selected to represent the motor inventory and were dissected for laboratory surveillance testing. The motors selected were S/N 0022135, cast date June 1963; S/N 0022583, cast date January 1964; and S/N 0022788, cast in July 1964. An additional motor, S/N 0022687, cast in April 1964, became available and was dissected in 1981 for continuing surveillance testing. The test data from Stage II dissected motors were assumed to have a normal population that could be combined. This was a fallacious assumption as shown in MAQCP Report Nr. 496(84) where individual regressions for each motor were made and compared using the analysis of covariance. There were four test periods for motor S/N 0022583, and seven for motors S/N 0022135 and S/N 0022788.

Subsequently, assets from these motors have been depleted. There have been three test periods for S/N 0022687. Data from motor S/N 0022123 was visually displayed on the multi-motor plots for comparison only.

Motor S/N 0022687 was dissected in a different manner from earlier motors. The distance between cuts B and C, and cuts C and D was increased to 16 inches (figures 1 and 2). Motor S/N 0022123 was dissected in the same manner as motor S/N 0022687.

Segments A, B, and C, from section 4 of motor S/N 0022583 were used for testing. Figure 3 illustrates the cutting plan for the latest test period. The general test directive (GTD-2 Dissect Amendment 2, April 1984) specified that test specimens be conditioned at controlled relative humidity. Other changes were different test temperatures for stress relaxation, deletion of some testing, and addition of mini-thin tensile from the bore area.

Motors which have been dissected to date are:

<u>Motor S/N</u>		<u>Cast Date</u>

STATISTICAL ANALYSIS

This is the first time motor S/N 0022123 has been tested, therefore, comparisons are mostly of a descriptive nature. The data was collected and the means and standard deviations were calculated for each test. In addition, "F" and 't' tests were performed on hardness data for conditioned and unconditioned specimens (Table 13). These tests were accomplished on hardness data because if there were any differences in the data it would be statistically noticeable in the hardness data. The "F" and 't' tests were also used the last time motor S/N 0022687 was tested. The variance on the hardness data were not consistent with the variance from motor S/N 0022123. There was only one significant result for the hardness test whereas in the previous report there were three. It is suspected that factors other than conditioning were responsible for the large variation between hardness data in these two motors.

The multi-regressions in this report are included for visual display only. It should be noted that the last time motor S/N 0022687 was tested the specimens were conditioned. The relative humidity (RH) conditioning of test specimens were accomplished within $35 \pm 5\%$ RH for a minimum of 14 days for specimens up to 1/2 inch thick and 35 days from specimens over 1/2 inch thick. The last two mean points on the plots were conditioned at controlled humidity. The other data points represent uncontrolled humidity conditioning.

Mini-thin plots were used to observe the differences between blocks for selected slices and differences between blocks. The mini-thin program shows

a profile of the propellant slices obtained at 0.1 inch intervals. Inner and outer test observations of mini-thin values were made for five parameters, i.e., maximum stress, strain at maximum stress, strain at rupture, stress at rupture, and modulus. The parameters were plotted for five of the 10 slices, in particular slices at 0.1, 0.2, 0.3, 0.6, and 1.0 inches.

The mini-thin plots are not regressions, but show sample relation lines. The horizontal axis represents the consecutive 0.10 inch slices in their order of cut as listed in each plot title. Data symbols are used to differentiate and identify one slice from another. The data groups used in mini-thin testing are labeled as to the motor orientation they were obtained from.

The test mean values of motor S/N 0022123 are overlayed onto the multi-regression trend lines for motors S/N 0022135, S/N 0022583, S/N 0022788, and S/N 0022687. No inferences can be made from the multi-plots which are included for visual observation only.

DEFINITION OF THE MASTER STRESS RELAXATION CURVE

The master stress relaxation curve is a composite curve representing the behavior of a polymer over a wide range of time and temperature relationships. From a curve constructed at a given strain level, any combination of time and temperature can be used to determine a corresponding stress relaxation modulus.

DETERMINATION OF STRESS RELAXATION MODULUS USING A MASTER STRESS RELAXATION CURVE

From test data at a particular strain level, a polymer's stress relaxation modulus corresponding to any combination of time and temperature can be determined. The horizontal axis of the master stress relaxation plot is a logarithmic value (t/a_T) , and the vertical axis is a linear value, $E(t)298/T$, where $E(t)$ is the stress relaxation modulus dependent on time. T is temperature in degrees Kelvin, a_T equals any relaxation time at temperature T divided by the corresponding time at the reference temperature (298 degrees Kelvin or 77°F), and ' t ' is relaxation time in seconds. The stress relaxation modulus for any combination of temperature and time can be determined by using the following steps:

a. For each stress relaxation plot there is associated a plot of temperature in degrees F versus $\log a_T$. From this plot, determine $\log a_T$ corresponding to the temperature at which stress relaxation modulus is desired.

b. Determine $\log 't'$ or $\log$ of the desired stress relaxation time.

c. Determine $\log (t/a_T)$ by using the equation:

$$\log (t/a_T) = \log t - \log a_T.$$

d. Place the determined value of $\log (t/a_T)$ in the horizontal axis of the large plot and reference the master stress relaxation curve to determine the corresponding value $E(t)298/T$ in the vertical axis.

e. Determine $298/T$ and divide into $E(t)298T$ to find $E(t)$, the stress relaxation modulus at the desired time and temperature.

TEST RESULTS

INTRODUCTION:

Testing in 1985 represents the first test period for motor S/N 0022123. Specimens were conditioned at controlled humidity $35 \pm 5\%$ as required by General Test Directive (GTD-2) Dissect Amendment 2, April 1984. Hardness was measured on the dog bone ends before and after conditioning.

In this report, multi-motor regression plots prepared from other dissected motor data are used to show the visual relationship of motor 0022123 to the other motors. As stated earlier, the motors cannot be statistically combined and data from motor S/N 0022123 was not incorporated in the data base for these plots. The newest motor (S/N 0022123) is merely overlaid on the plots generated for MAQCP Report 514(86) by the Symbol (◇).

A. UNIAXIAL TENSILE TESTS:

1. Very low rate tensile (0.0002 in/min CHS): Testing was not performed since the equipment was not functional during this test period. This applies to both inner and outer tests.

2. Low Rate Tensile:

a. OUTER: Data are listed in Table 1. Mean values are indicated on figures 4 thru 8. Motor S/N 0022123 (◇) was cast 63163 and motor S/N 0022135 (□) was cast 63162. Strain at maximum stress and strain at rupture for motor S/N 0022123 appears to be closer to the data from motor S/N 0022135 than to the other dissected motors.

b. INNER: The mean values for all motors tested are indicated on figures 9 thru 13. Similarity to motor S/N 0022135 is even more noticeable for inner propellant. Whether this relationship continues depends on results from follow-up testing.

B. BIAXIAL TENSILE TEST:

Data are listed on Table 2.

OUTER: The mean values are indicated on figures 14 thru 18. Strain values are outside the 90-90 band of the multi-motor regressions, again showing a similarity to motor S/N 0022135.

INNER: The mean values for all motors tested are indicated on figures 19 thru 23. Maximum stress and modulus for motor S/N 0022123 is above the regression line as compared to all points for S/N 0022135 (figures 19 and 23). Strain at maximum stress and strain at rupture for motor S/N 0022123 is below the regression line as is S/N 0022135 (figures 20 and 22).

C. HIGH RATE HYDROSTATIC TEST:

Data are listed on Table 2.

OUTER: The mean values for all motors tested are indicated on figures 24 thru 28. Except for strain at maximum stress and strain at rupture (figures 25 and 27) which are well below the regression line; motor S/N 0022123 values falls just below the regression line on the multi-motor plots.

INNER: The mean values for all motors tested are indicated on figures 29 thru 33. The similarity between motors S/N 0022135 and S/N 0022123 is apparent for strain at maximum stress and strain at rupture.

D. MINI-THIN TENSILE:

Mini-thin tensile specimens are cut from the case and bore areas as shown in figure 3. The blocks were not conditioned and specimens were tested the day after being cut to 0.1 inch slices. The values for each block are plotted as shown in figures 34 thru 43. The values are not consistent as no pattern is apparent for either inner or outer propellant. There is a difference in mean values and standard deviations for each block (Tables 4 thru 8).

In an effort to determine any similarities among slices, the position within the block, values were plotted for each parameter. These plots are shown in figures 44 thru 53. Again no pattern is apparent.

E. STRESS RELAXATION:

The master stress relaxation curves are shown in figures 54 and 55. The master curve is flatter than the curves which had test temperatures below 0°F. Table 9 lists the mean values. The points are indicated on figures 56 thru 63. Inner propellant from motor S/N 0022123 is above the regression line of the multi-motor plots. The data from motor S/N 0022135 is completely above the trend line for both inner and outer testing. None of the other motors tested show data above the regression trend line.

F. THERMAL COEFFICIENT OF LINEAR EXPANSION: (TCLE)

Table 10 lists the data, means, and standard deviations. Figures 64 thru 69 shows data from all of the motors are scattered including motor S/N 0022123. The point is not consistently above nor below the regression slope line.

G. HARDNESS:

The tensile specimens were tested for hardness when first machined. After conditioning at $35 \pm 5\%$ RH, hardness readings were taken a second time. These data are listed in Table 11. There is a significant difference between the means of 10 sec readings on inner propellant (Table 13). The data are indicated on figures 70 and 71.

H. BOND PROPERTIES:

SHEAR: Poker chip specimens which are 2 inches in diameter with the Avcoat removed, were tested under 500 psi at 2 in/min and 20 in/min. The data are listed in Table 14. Failure mode at the lower speed is mostly caused due to the peeling of liner from propellant with failure in the propellant layer and minimally in the liner. At 20 in/min failure is chiefly in the propellant, with some failure in the liner and between liner and insulation.

CONSTANT LOAD TENSILE: Sleeved tensile specimens (2 inch diameter with fillet to reduce diameter to 1.5 inch) are tested with varying loads to cause failure at different times. When log stress is plotted vs log time, an equation is derived which gives failure loads at specific times. The data are listed in Table 14.

I. MISCELLANEOUS PROPERTIES:

Chemical properties on liner and insulation were not determined. These tests will be done on material from the forward dome which was not available during this test period.

CONCLUSIONS AND RECOMMENDATIONS

CONCLUSION:

1. The most striking aspect of testing this motor is the apparent relationship to motor S/N 0022135. The relationship is visual, since no numerical inferences can be drawn with only one set of data. Moreover, since motor S/N 0022123 was approximately 21 years old when first dissected there can be no age correlations.

2. Only hardness testing had data from specimens which were tested before and after conditioning. Statistically, one of four parameters was significant. However, the next test period will use specimens which are unconditioned and conditioned. These specimens will not be from locations stipulated in the test plan nor will numbers be the same as required due to insufficient propellant.

RECOMMENDATIONS:

Continued testing of motor S/N 0022123 is needed to determine if the aging pattern is similar to that of motor S/N 0022135 or if it resembles one of the other motors in the (RSLP) program. The main need for continued testing is to help determine if these motors are capable of supporting the flight programs in the late 80's and early 90's.

19. KEY WORDS (Continue on reverse side if necessary and identify by block number) Minuteman Solid Propellant Dissected Motors		
20. ABSTRACT (Continue on reverse side if necessary and identify by block number) This report contains data from first time testing of dissected Minuteman II Stage II motor S/N 0022123 assigned to the Reentry System Launch Program (RSLP). No statistical inferences were determined with only one set of data, except for hardness, where humidified and non-humidified specimens were tested. Data have been overlayed on multi-motor regression plots for visual reference only. Plots have been made to show differences between different blocks and slices of propellant within the same motor used for mini-thin tensile tests.		

Visual observation indicates this motor resembles motor S/N 0022135 more closely than any of the previously tested dissected motors.
