1.0 SUMMARY

This is the final report for the program of Measurement of Heat Transfer and Pressure Drop in Rectangular Channels with Turbulence Promoters. This project was conducted by the Turbomachinery Laboratories of the Texas A&M University and was funded through Curtis Walker at the U.S. Army Research and Technology Laboratories. The project was monitored by Robert Boyle at the NASA-Lewis Research Center under NASA Contract No. NAS3-24227.

Periodic rib turbulators have been used in advanced turbine cooling designs to enhance the internal heat transfer. The previous studies (NASA CR 3837) showed that the slant ribs provided a higher heat transfer than that the transverse ribs in a square channel for a constant pumping power. The objective of the present project was to investigate the combined effects of the rib angle-of-attack and the channel aspect ratio on the local heat transfer and pressure drop in rectangular channels with two opposite ribbed walls for Reynolds number varied from 10,000 to 60,000. The channel aspect ratio (W/H) was varied from 1 to 2 to 4. The rib height-to-hydraulic diameter ratio (e/D) was varied from 0.047 to 0.078, the rib pitch-to-height ratio (P/e) was varied from 10 to 20, and the rib angle-of-attack (α) was varied from 90° to 60° to 45° to 30° , respectively.

The highly detailed heat transfer coefficient distribution on both the smooth side and the ribbed side walls from the channel sharp entrance to the downstream region were measured. The results did confirm that, in the square channel, the heat transfer for the slant ribs ($\alpha = 30^\circ$ - 45°) was about 30% higher than that the transverse ribs ($\alpha = 90^\circ$) for a constant pumping power. However, in the rectangular channels ($W/H = 2$ and 4 , ribs on W side), the heat transfer at $\alpha = 30^\circ$ -

45° was only about 5% higher than that $\alpha = 90^\circ$. The results also showed that, in the square channel, the highest heat transfer was obtained at $\alpha = 60^\circ$ accompanying with the highest pressure drop, however, in the rectangular channel with $W/H = 4$, both the highest heat transfer and pressure drop were obtained at $\alpha = 90^\circ$. The average heat transfer and friction correlations were developed to account for rib spacing, rib angle, and channel aspect ratio over the range of roughness Reynolds number. The correlations can be used in the design of gas turbine airfoil cooling passages.

2.0 INTRODUCTION

2.1 Background

In advanced gas turbine blades and vanes, turbulence promoters (rib turbulators) are cast onto two opposite walls of the shaped internal cooling passages to enhance the heat transfer to the cooling air. The cutaway views of a typical advanced gas turbine airfoil are shown in Figure 1. The internal cooling passages can be approximately modeled as rectangular channels with two opposite rib-roughened walls. In [1] and [2, 3], the effects of the rib pitch-to-height ratio (P/e 10 to 40), the rib height-to-channel hydraulic diameter ratio ($e/D = 0.021$ to 0.063), and the rib angle-of-attack ($\alpha = 30^\circ$ to 90°) on the average heat transfer and the pressure drop for fully developed turbulent air flow ($Re = 7,000$ to $90,000$) in a uniformly heated, straight, square channel with two opposite ribbed walls were systematically investigated. The results showed that, at $P/e = 10$ to 20 , the maximum heat transfer occurred at rib angles-of-attack between 60° and 75° , whereas the optimum heat transfer occurred at rib angles-of-attack between 30° and 45° . The maximum heat transfer was defined as the highest heat transfer rate which occurred at the cost of the highest pressure drop, while the optimum heat transfer was defined as the highest heat transfer rate which could be obtained for a given constant pumping power. Semi-empirical correlations for friction factor and heat transfer coefficients were developed to account for rib spacing and rib angle over the range of Reynolds number.

The friction and average heat transfer results obtained for fully developed flow in [1-3] can serve as reference data for turbine airfoil internal cooling designs. However, the results obtained in [1-3] are primarily for the square channel with two opposite ribbed walls. The

effect of the channel aspect ratio on the heat transfer performance is lacking. Moreover, the local heat transfer coefficient on both the smooth side and the rib-roughened side walls of the test channel, from the channel entrance to the downstream region, has not been reported. The local heat transfer coefficient distribution is essential to engineers in the design of effectively cooled turbine airfoils which are not susceptible to structural failure due to uneven metal temperature distributions. Therefore, a systematic investigation to determine the combined effects of the flow channel aspect ratio (W/H), the rib geometry ($P/e, \alpha$), and the roughness Reynolds number (e^+) on the local heat transfer coefficient distribution should be performed.

2.2 Objective

The objective of the project was to investigate the combined effects of the channel aspect ratio and the rib angle-of-attack on the friction factor and the local and the average heat transfer coefficients in rectangular channels with two opposite ribbed walls for Reynolds number varied from 10,000 to 60,000. Three flow channel aspect ratios (W/H) were examined, namely, 1, 2, and 4, respectively. In each channel, periodic ribs were placed on the channel width side (W). The rib height-to-hydraulic diameter ratio (e/D) was varied from 0.047 to 0.078, the rib pitch-to-height ratio (P/e) was varied from 10 to 20, whereas the corresponding rib angle-of-attack (α) was varied from 90° to 60° to 45° to 30° , respectively. The local heat transfer coefficient distributions on the smooth side and the ribbed side walls, from the channel entrance to the downstream region, were measured. Heat transfer performance was compared, and the best rib geometry was identified. Semi-empirical correlations for the average friction and heat transfer coefficients were developed to account for channel aspect ratio, rib

spacing, and rib angle. The correlations can be used in the design of gas turbine airfoil cooling passages.

3.0 EXPERIMENTAL APPARATUS AND DATA REDUCTION

3.1 Experimental Apparatus

A schematic of the experimental apparatus is shown in Figure 2. A 5 HP blower forced air through a settling chamber and a 4 in. diameter pipe, equipped with a 1.5 in. diameter orifice plate to measure flow rate. A plexiglass plenum was connected between the pipe and the test channel, to ensure that the air entering the test channel had a sharp contraction entrance condition. At the end of the test channel, the air was exhausted into the atmosphere. The Reynolds number based on the channel hydraulic diameter (D) was varied between 10,000 and 60,000.

Both square and rectangular channels were constructed. The square channel had a cross-section of 2" x 2", while the rectangular channel I had 4" x 2". The same rectangular channel I was also served as the rectangular channel II by replacing the channel height (H) from 2" to 1". The periodic ribs were placed on the channel width (W) side. The dimensions of the three test channels and the associated plenums are shown in Figure 3.

The rectangular channel I ($W/H = 4"/2"$) consisted of four wood-plexiglass plates with a total thickness of 0.75 in., as shown in Figure 4. Each plate was covered separately by the 0.001 in. thick stainless steel foil, which was cemented to the front surface of each plate and could be individually controlled by a variac transformer, to provide a controllable electrical heat to the test channel. A single strip foil with a width of $1\frac{7}{8}"$ was used for the channel height (H) side. Meanwhile, three parallel strip foils with each a width of $1\frac{1}{4}"$, connected in series from one end to the other by the buss bar, was used for the channel width (W) side, as shown in Figure 4.

The same rectangular I was also used for the rectangular channel II ($W/H = 4"/1"$) by changing the strip foil on the channel height (H) from a width of $1\frac{7}{8}"$ to that of $\frac{7}{8}"$. The square channel ($W/H = 2"/2"$) was constructed in a same way as that of the rectangular I, except that a single strip foil with a width of $1\frac{7}{8}"$ was used separately for each side wall of the channel.

For the case of ribbed channel tests, the brass ribs of a square cross-section were glued periodically in line onto the top and bottom plates (i.e., the width side of the channel) of the foil-heated channels in a required distribution. The rib geometries for each test channel are shown in Figure 5.

The detailed thermocouple locations for each test channel are shown in Figure 6. The square channel had 180, 36 gauge, copper-constantan thermocouples in the strategic locations to measure the local surface temperature. Ninety of them were placed on the bottom ribbed wall (channel width side), while the other ninety on the right hand side smooth wall (channel height side). Sixty out of each ninety thermocouples were placed along the centerline of the ribbed and the smooth walls, respectively. The rest of each thirty thermocouples were well distributed on the middleline and the edgeline of each walls, as shown in Figure 6. The thermocouple locations for the rectangular channel I were similar to that the square channel. In order to check the symmetry of thermocouple readings on the opposite smooth walls, there were two thermocouples placed on the left hand side smooth wall (LHS), at the downstream region of the channel I. The same bottom ribbed wall of the rectangular channel I was used for that of the rectangular channel II. But, on the right hand side smooth wall (RHS) of the channel II, the thermocouples were only placed along the

centerline of the test plate. The thermocouples were soldered underneath the thin foil through holes in the wood-plexiglass plate, as shown in Figure 7. Each test channel was well insulated by fiberglass material. A Fluke 2280 A Data Logger and a TI PC were used for temperature readings and storages.

The pressure tap locations are shown in Figure 8. Six pressure taps along the top ribbed wall, and the other six along the left hand side smooth wall were used for the static pressure drop measurements. A pressure tap was also installed in the plenum to check the static pressure of air entering the test channel. A Dywer Microtector with an accuracy up to 0.001" water was used for pressure drop measurements in the test channel. Figure 9 shows a photograph of the test channels.

3.2 Data Reduction

The local heat transfer coefficient was calculated from the local net heat transfer rate per unit surface area from the wall to the cooling air, the local wall temperature, and the local bulk mean air temperature as

$$h = \frac{q}{A(T_w - T_b)} \quad (1)$$

Equation (1) was used respectively for the ribbed side wall and the smooth side wall heat transfer coefficient calculations. The local net heat transfer rate was the electrical power generated from the foil, subtracting heat loss to the outside of the test channel. The electrical power generated from the foil was determined from the measured foil resistance and the current through the foil on each plate. The electrical power was also checked with the measured voltage drop

across the foil on each plate. In order to place the results on a common basis, the heat transfer area used in equation (1) was always that of a smooth foil on each wall. It was found that the foil provided a nearly uniform heat flux on each wall of the test channel. The maximum heat loss from the ribbed side wall and the smooth side wall was estimated to be less than 3% and 5%, respectively, for Reynolds numbers greater than 10,000. The net heat flux (q/A) level was varied from about 300 to 800 Btu/hr-ft² depending upon the test conditions.

The local wall temperature used in equation (1) was derived from the thermocouple measurement. The bulk mean air temperatures entering and leaving the test channel were measured by thermocouples which could be travelled vertically and horizontally. The local bulk mean air temperature used in equation (1) was calculated, assuming a linear air temperature rise along the flow channel. It was checked that the total net heat transfer from the test channel to the cooling air agreed well with the cooling air enthalpy rise along the test channel. The inlet bulk mean air temperature was about 75° to 85°F depending upon the test conditions.

The reported local Nusselt number was normalized by the Nusselt number for the fully developed turbulent channel flow derived by Dittus and Boelter as

$$\frac{Nu}{Nu(FD)} = \frac{hD/K}{0.023 Re^{0.8} Pr^{0.4}} \quad (2)$$

The maximum uncertainty in the Nusselt number was estimated to be less than 8% for Reynolds numbers larger than 10,000 by using the uncertainties estimation method in [4].

The pressure drop across the test channel was measured by a microtector. In fully developed channel flow, the average friction factor was calculated from the pressure drop across the flow channel and the mass flow rate of the air as

$$\bar{f} = \frac{\Delta P}{4(L/D)(G^2/2\rho g_c)} \quad (3)$$

The average friction factor of the present investigation was based on the adiabatic conditions (tests without heating). The maximum uncertainty in the average friction factor was estimated to be less than 9% for Reynolds numbers greater than 10,000.

4.0 EXPERIMENTAL RESULTS

4.1 Experimental Results for Smooth Channels

The typical results for the four-sided smooth channels are shown in Figures 10-12. In general, the local Nusselt number ratios along the bottom wall (channel width side) and the right hand side (RHS) wall of the test channels exhibit the same trend, except that the local Nusselt number ratios along the right hand side wall (channel height side) are slightly higher than that along the bottom wall for the rectangular channels I and II, respectively. It can be seen that flow separation occurs right after the entrance due to sharp contraction, and then the flow reattachment attains at about $0.5 D$ from the entrance, producing a high heat transfer coefficient. At further downstream from the entrance, for the square channel the Nusselt numbers are about 5 to 10 percent higher than that the fully developed turbulent flow results, while for the rectangular channels the Nusselt numbers are about 5 to 20 percent higher than that the fully developed values.

The experimental results from Boelter, Young, and Iversen [5] and Sparrow and Cur [6] are also included in Figures 10-12 for comparisons. In reference [5], the results were obtained for flow in a circular tube with a sharp entrance and heated by condensing steam. In reference [6], the data were based on the local measurements for flow in a high-aspect-ratio rectangular duct ($W/H = 18$) with a sharp entrance by using the Naphthalene sublimation technique. In the developing region ($X/D = 1 \sim 6$), the present data agree qualitatively with those of [5] and [6]. In the fully developed region ($X/D = 8 \sim 10$), the present data agree fairly well with those of [5] and [6]. It is interesting to note that both the present study and the reference [6] show that the flow reattachment attains at about $0.5 D$ from the entrance. These smooth channel results

prove that the test sections are reliable to reproduce data for the cases when the periodic ribs are applied.

The average friction factor and the average heat transfer coefficient in the fully developed region are shown in Figure 13 and compared with the results given in the literature. The friction factor differs by up to 12% from the Blasius friction factor equation, and the Nusselt number differs by up to 10% from the Dittus-Boelter equation. The Blasius equation for the four-sided smooth channel friction factor is:

$$f(FD) = 0.079 (Re)^{-0.25} \quad (4)$$

The Dittus-Boelter equation for the four-sided smooth channel heat transfer is:

$$Nu(FD) = 0.023 Re^{0.8} Pr^{0.4} \quad (5)$$

4.2 Experimental Results for Rib-Roughened Channels

The brass ribs of a square cross-section were glued periodically in-line onto the top and bottom walls of the test channels in patterns to achieve the desired spacing and angle-of-attack. In each channel, a total of eight rib geometries (two rib spacings, $P/e = 10$ and 20 ; each rib spacing having four different rib angles-of-attack, $\alpha = 90^\circ, 60^\circ, 45^\circ$, and 30°) were tested respectively for three Reynolds numbers, $Re = 10,000, 30,000$, and $60,000$, as indicated in Figure 5. Additionally, the rectangular channels I ($W/H = 4"/2"$, ribs on W side) and II ($W/H = 4"/1"$, ribs on W side) were modified to become the rectangular channels IA ($W/H = 2"/4"$, ribs on W side) and IIA ($W/H = 1"/4"$, ribs on W side), respectively, by simply replacing the periodic ribs from the top and

bottom walls to the right and left hand side walls, for two rib spacings ($P/e = 10$ and 20), one rib angle ($\alpha = 90^\circ$), and three Reynolds numbers, respectively. The detailed raw data for all test runs are given in Appendix. Only the most representative results will be presented as follows.

4.2.1 Local Heat Transfer and Pressure Drop Data

Figures 14-16 show the typical local temperature distribution along the centerline in both the bottom ribbed wall and the RHS smooth wall of the test channels. As expected that the ribbed wall heat flux is higher than the smooth wall. These wall temperature profiles were used for determining the local heat loss through the test plate and the insulation material to the outside of the test channel. These wall temperature profiles were also used for calculating the local heat transfer coefficient according to equation (1).

Effect of rib spacing. The typical results to illustrate the effect of rib spacing on the centerline heat transfer coefficient on both the ribbed side wall and the smooth side wall of the test channels are shown in Figures 17-19 for the case of $Re = 30,000$ and $\alpha = 90^\circ$. The results show that the local Nusselt number ratios on the RHS smooth wall of the ribbed channels decrease sharply with distance for both P/e ratios. These are similar to the four-sided smooth channel results, except that the former have some small fluctuations and about 20-100% higher values than that the latter, due to the influence of the adjacent periodic ribs. However, the local Nusselt number ratios on the ribbed side wall have larger fluctuations and decrease slowly with distance after the first two ribs ($X/D > 2.0$), due to flow separation from ribs and reattachment between ribs. For the case of $P/e = 10$, heat transfer coefficients increase after flow separating from ribs and decrease after

flow reattaching on the surface (about 4 rib height downstream from separation) and then increase again before flow hits next rib.

For the case of $P/e = 20$, the similar flow and heat transfer patterns are observed, except that heat transfer coefficients are about 10-20% lower than that of $P/e = 10$, because of wider rib spacing creating thicker boundary layer thickness after flow reattachment between ribs. The periodic heat transfer profiles are obtained after $X/D > 3$. At $X/D < 1.0$, for both $P/e = 10$ and 20 the Nusselt number ratios on both the ribbed side and the smooth side walls are about the same, while at $X/D > 1.0$, the ribbed side wall Nusselt number ratios are gradually departed from that the smooth wall values and up to about two times higher at the downstream fully developed region, $X/D > 7.5$.

Effect of Reynolds number. The typical results to demonstrate the effect of Reynolds number on the centerline heat transfer coefficient of the ribbed channels are shown in Figures 20-22 for the case of $P/e = 20$ and $\alpha = 90^\circ$. In general, the Nusselt number ratios for $Re = 10,000$ and 60,000 shown in Figures 20-22 have the same trend as that for $Re = 30,000$ shown in Figures 17-19. It can be seen that flow tends to reattach quicker for $Re = 60,000$, about 2 rib height downstream from separation, than that for $Re = 10,000$, about 6 rib height downstream from separation. Therefore, the Nusselt number ratio decreases with increasing Reynolds number.

Effect of channel aspect ratio. The typical results to show the effect of channel aspect ratio on the centerline heat transfer coefficient are shown in Figures 23-24 for the case of $\alpha = 90^\circ$ and $Re = 30,000$. In general, the Nusselt number ratios on both the ribbed side and the smooth side walls show the same trend for different channel

aspect ratios. It can be seen that the Nusselt number ratio gradually increases with increasing channel aspect ratio. This is because that, for the same rib geometry ($e/D = 0.047$, $\alpha = 90^\circ$, $P/e = 10$ or 20) and flow condition ($Re = 30,000$), the high aspect ratio channels ($W/H = 2, 4$) have wider ribbed side surfaces (i.e., narrower smooth side walls) to produce higher heat transfer coefficient, while the low aspect ratio channels ($W/H = 1/2, 1/4$) have narrower ribbed side surfaces (i.e., wider smooth side walls) to produce lower heat transfer coefficient.

Combined effects of rib angle-of-attack and channel aspect ratio.

The typical results to show the combined effects of rib angle-of-attack and channel aspect ratio on the centerline heat transfer coefficient are plotted in Figures 25-27 for the case of $P/e = 10$ and $Re = 30,000$. In general, the heat transfer patterns of the ribbed side wall are non-similar for different rib angle-of-attack. In the square channel, the Nusselt number ratio for $\alpha = 90^\circ$ maintains about the same level after $X/D > 3$, which implies that the periodic heat transfer distribution at the downstream region ($X/D > 7.5$) is observed. It can be seen that the Nusselt number ratio for $\alpha = 60^\circ, 45^\circ$, and 30° increase after $X/D > 3$. Therefore, at $X/D > 3$, the Nusselt number ratio for $\alpha = 60^\circ, 45^\circ$, and 30° , is higher than that for $\alpha = 90^\circ$. However, as shown in Figure 26, the rib angle effect on the local heat transfer is reduced for the rectangular channel I ($W/H = 2$) and the rib angle effect is completely diminished for the rectangular channel II ($W/H = 4$) as shown in Figure 27. In other words, in rectangular channel II the Nusselt number ratio for $\alpha = 90^\circ$ is higher than that for $\alpha = 60^\circ, 45^\circ$, and 30° , respectively.

In order to examine closely the combined effects of rib angle and channel aspect ratio on the local heat transfer behavior at the downstream region, the typical Nusselt number ratios ($Nu/Nu(FD)$) are

tabulated in Figures 28-30 for $P/e = 10$ and $Re = 30,000$. In the square channel as shown in Figure 28, for $\alpha = 90^\circ$ the Nusselt number ratio on the ribbed side wall varies periodically in the streamwise (axial) direction, and the edgeline Nusselt number ratio is slightly higher than that the centerline values. For $\alpha = 60^\circ$, 45° , and 30° , the Nusselt number ratio on the ribbed side wall varies in both the streamwise and the spanwise (lateral) directions, and the edgeline Nusselt number ratio is much higher than that the centerline values. Meanwhile, the centerline Nusselt number ratio for $\alpha = 60^\circ$, 45° , and 30° , is higher than that for $\alpha = 90^\circ$ at the same values of e/D , P/e , and Re .

In the rectangular channel I ($W/H = 2$) as shown in Figure 29, for $\alpha = 90^\circ$ the Nusselt number ratio behaves similarly to that the square channel as discussed above. However, for $\alpha = 60^\circ$, 45° , and 30° , the edgeline Nusselt number ratio is lower, instead of higher in the case of the square channel, than that the centerline values. Meanwhile, the centerline Nusselt number ratio for angled rib ($\alpha = 60^\circ$ et al.) is only slightly higher than that the transverse rib ($\alpha = 90^\circ$) at the same values of e/D , P/e , and Re . In the rectangular channel II ($W/H = 4$) as shown in Figure 30, the Nusselt number ratio shows the same trend as that in the rectangular channel I for all different rib angles, except that the centerline Nusselt number ratio for angled rib is now lower than that the transverse rib at the same conditions.

At this point, we find that the angled rib has the biggest effect for the square channel ($W/H = 1$), however, the effect is diminished for the rectangular channel II ($W/H = 4$). The same conclusions are also applied for the case of $P/e = 20$ and other Reynolds numbers. It also can be seen that, on the smooth side wall, the edgeline Nusselt number

ratios are always higher than that the centerline values in each channel due to the adjacent rib effect. Meanwhile, in the square channel the smooth side wall Nusselt number ratios for the angled rib are higher than that for the transverse rib, but in the rectangular channels the smooth side wall Nusselt number ratios for the angled rib are much lower than that for the transverse rib.

Figure 31 shows the effect of rib orientations on the temperatures of the opposite smooth walls in the square and rectangular channels. It can be seen that, in the square channel [1], the temperatures on both the RHS and LHS smooth walls are about the same for all α . However, in the rectangular channel I, the temperatures on both smooth walls are about the same only for $\alpha = 90^\circ$. When $\alpha = 60^\circ$, 45° , and 30° , the temperatures on the RHS smooth wall are much higher (30-40% higher) than that on the LHS smooth wall. This implies that the RHS smooth wall heat transfer is lower than that the LHS smooth wall for the rectangular channel I with angled ribs.

The present square channel results confirm what we observed in our previous report [1], except that in the present square channel the highly detailed heat transfer distributions along the ribbed side and the smooth side walls are obtained. However, the rib angle effect for the rectangular channels are beyond our expectations. Based on this observations, it seems that a highly swirling flow (or secondary flow) may be created along the rib angle direction from the left hand side edge to the right hand side edge producing a higher heat transfer at the edgeline than that the centerline for the square channel. However, this swirling flow generated by the angled rib may be damped away for the rectangular channel II ($W/H = 4$, ribs on W side) due to the wider ribbed side wall and the narrower smooth side wall (i.e., the swirling flow

cannot penetrate into the edge, or boundary layer effect on the edge). This may be the reason why the angled rib heat transfer is lower than that the transverse rib for the rectangular channel II, and the edgeline heat transfer is lower than that the centerline on the ribbed side wall and the LHS smooth wall heat transfer is higher than that the RHS smooth wall for the rectangular channel with angled ribs. It is suggested that this results need to be further investigated and confirmed.

Local pressure drop data. Figures 32-34 show the pressure drop ($\Delta P = P - P_{atm}$) along the test channels for $P/e = 10$ and $Re = 30,000$. In the square channel the 60° rib angle produces the highest pressure drop than other rib angles. However, the rib angle effect is gradually decreased for the rectangular channel I, and diminished for the rectangular channel II. It is noted that the pressure distribution is approximately a linear when $X/D > 5$ for all tests. These figures also indicate that the sharp pressure drop between the plenum and the channel entrance is about the same for a given Reynolds number in a given channel regardless the rib angles in each channel.

4.2.2 Average Heat Transfer and Pressure Drop Data

In order to develop the heat transfer and friction correlations and to compare the heat transfer performance in each channel, the average heat transfer coefficient and friction factor are required. Based on the local heat transfer and pressure distribution, it was found that, for $\alpha = 90^\circ$, the Nusselt number became a periodic profile and the friction factor became a constant value in the region where $X/D > 3$. Therefore, the heat transfer and pressure data in the region with $X/D > 3$ in each channel was used to provide the average Nusselt number and the average friction factor, respectively. In this report, the average

Nusselt number on both the smooth and the ribbed side walls was based on the average value of the centerline Nusselt number between $X/D = 2.9-3.7$ and $X/D = 8.5-9.4$ for both the square channel and the rectangular channel I. The average Nusselt number was the average value of the centerline Nusselt number between $X/D = 4.8-6.2$ and $X/D = 14.2-15.6$ for the rectangular channel II. The average Nusselt numbers and the average friction factor for all test runs are tabulated in Appendix. Only the most representative results are discussed here.

The typical results to show the effect of Reynolds number and P/e ratio on the ~~Nusselt number and friction factor ratios~~ Nusselt number and friction factor ratios in each channel are plotted in Figures 35-37 for the case of $\alpha = 90^\circ$. As expected that the average heat transfer ratios on both the ribbed and smooth walls decrease with increasing with Reynolds number for all channels, whereas the average friction factor ratios increase with Reynolds number. The results also show that, for a given Reynolds number, both the average heat transfer and friction factor ratios decrease with increasing the P/e ratio for all channels. The typical results to illustrate the effect of the channel aspect ratio on the average heat transfer and friction ratios are also shown in Figures 36-37. Again the results show that the average Nusselt number and friction factor ratios increase with increasing the channel aspect ratio from 1/2 to 2, and 1/4 to 4.

The typical results to illustrate the combined effects of the channel aspect ratio and the rib angle on the average heat transfer and the average friction factor ratios are shown in Figures 38-40. In the square channel, both the average Nusselt number and friction factor ratios increase with decreasing α and reach a maximum value at $\alpha = 60^\circ$, then decrease with further decreasing α . In the rectangular channel I, both the average Nusselt number and friction factor ratios increase very

much slightly with decreasing α and reach a peak value at $\alpha = 60^\circ$, then decrease with further decreasing α . However, in the rectangular channel II, both the average heat transfer and friction factor decrease monotonically with decreasing α .

4.2.3 Heat Transfer Performance Comparison

The typical results of the increased Stanton number of the ribbed side wall, $St(R)/St(FD)$, and the accompanying increased average friction factor, $\bar{f}/f(FD)$, in each channel vs α for $P/e = 10$ and $Re = 30,000$ is shown in Figure 41. It is noted that, in the square channel, both the highest Stanton number and friction factor ratios occur at $\alpha = 60^\circ$, however, in the rectangular channel II (4" x 1"), both the highest Stanton number and friction factor ratios occur at $\alpha = 90^\circ$. Specifically, in the square channel the Stanton number ratio at $\alpha = 60^\circ$ is about 30% higher than that at $\alpha = 90^\circ$ and the accompanying friction factor ratio is about 40% higher.

The typical efficiency index, $St(R)/St(FD)/(\bar{f}/f(FD))$, in each channel vs α for $P/e = 10$ and $Re = 30,000$ is shown in Figure 42. The Stanton number shown in the upper plot of Figure 42 was that of the ribbed side wall, while the Stanton number shown in the lower plot of Figure 42 was that of the average value (weighted by area) between the ribbed side and the smooth side walls. It can be seen that the 30° rib has the highest efficiency index and the 60° rib has the lowest in each channel. At any rib angle, the square channel has a better efficiency index than the rectangular channels I and II.

One of the performance evaluation criteria was to compare the increased heat transfer, $St(R)/St(FD)/(\bar{f}/f(FD))^{1/3}$, for equal surface area and pumping power as presented in [1, 3]. The typical results of

the effect of rib angle on the increased heat transfer in each channel is shown in Figure 43 and Figure 44, respectively, for $Re = 30,000$ and $\bar{e}^+ = 200$. The results show that the highest heat transfer for a constant pumping power occurs at $\alpha = 30^\circ$ for the square channel and at $\alpha = 45^\circ$ for the rectangular channels I and II. Specifically, in the square channel the increased heat transfer at $\alpha = 30^\circ$ is about 25% higher than $\alpha = 90^\circ$, however, in the rectangular channels I and II, the increased heat transfer at $\alpha = 45^\circ$ is only about 5% higher than $\alpha = 90^\circ$. Similarly, for a typical average roughness Reynolds number $\bar{e}^+ = 200$, in the square channel the increased heat transfer at $\alpha = 30^\circ$ is about 30% higher than $\alpha = 90^\circ$, while in the rectangular channels I and II, the increased heat transfer at $\alpha = 45^\circ$ is only about 5% higher than $\alpha = 90^\circ$.

The increased heat transfer for a constant pumping power vs α , or vs W/H , is summarized in Figure 45 for $\bar{e}^+ = 200$. One can conclude that, in general, the square channel ($W/H = 1$) provides a better heat transfer than the rectangular channels ($W/H = 2, 4$). In the square channel, the heat transfer increases with decreasing the rib angle, however, in the rectangular channels, the dependence of the heat transfer on the rib angle is dramatically reduced. The heat transfer for rectangular channels with $W/H = 1/2$ and $1/4$ (ribs on the W side) at $\alpha = 90^\circ$ is also included in Figure 45 for reference. Unfortunately, the data with other rib angles are not available.

4.2.4 Heat Transfer and Friction Correlations

For the results of the rectangular channels with turbulence promoters to be most useful for designers, general correlations are required for both the average heat transfer and friction which cover a wide range of parameters, e/D , P/e , α , W/H , and Re .

Based on the theoretical analysis derived in [2] for fully developed turbulent flow in rectangular channels with four sided ribbed walls, the friction factor, the channel aspect ratio, and the rib height-to-hydraulic diameter ratio, should be able to be correlated into a so-called momentum transfer roughness function, R , as

$$R = (2/f_r)^{1/2} + 2.5 \ln[(2e/D)(2W/(H+W))] + 2.5 \quad (6)$$

In order to apply equation (6) for rectangular channels with two opposite ribbed walls of the present study, the friction factor may be replaced by the average friction factor (weighted by area), as discussed in [2], by

$$f_r = \bar{f} + (H/W)(\bar{f} - f_s) \quad (7)$$

By substituting equation (7) into equation (6), the momentum transfer roughness function of the present study can be written as

$$R = \left[\frac{2}{\bar{f} + (H/W)(\bar{f} - f_s)} \right]^{1/2} + 2.5 \ln[(2e/D) \cdot (2W/(H+W))] + 2.5 \quad (8)$$

where f_s , the friction factor in smooth rectangular channels, can be calculated from equation (4).

Correlation of the present friction data is shown in Figures 46-47. The data for the non-geometrically similar roughness are displaced due to their different value of α , W/H , and P/e . The dependence of R on α , P/e , and W/H shown in Figure 47 is

$$R/[(P/e/10)^{0.35}(W/H)^m] = 12.31 - 27.07(\alpha/90^\circ) + 17.86(\alpha/90^\circ)^2 \quad (9)$$

Where $m = 0$, for $\alpha = 90^\circ$

$m = 0.35$, for $\alpha < 90^\circ$, if $W/H > 2$, let $W/H = 2$.

The average friction factor ($\bar{f}$) can be determined by combining equations (8) and (9) for a given e/D , P/e , α , W/H , and Re .

Similarly, in rectangular channels with four sided ribbed walls, the friction factor, the momentum transfer roughness function, and the Stanton number, can be correlated into a so-called heat transfer roughness function, H , as

$$H = R + [f_r/(2 St_r) - 1]/(f_r/2)^{1/2} \quad (10)$$

To apply equation (10) for rectangular channels with two opposite ribbed walls of the present study, the Stanton number in equation (10) should be replaced by the average Stanton number (weighted by area) in the following equation, according to [2],

$$St_r = \bar{St} + (H/W)(\bar{St} - St_s) \quad (11)$$

where St_s , the Stanton number in smooth rectangular channels, can be calculated from equation (5).

Correlation of the present heat transfer data is shown in Figures 48-49. No significant dependence of H (heat transfer roughness function) on P/e and W/H (channel aspect ratio) is observed. For a Prandtl number of 0.7 of the present study, the dependence of H on α and e^+ can be represented by

$$H = 1.88(W/H)^{0.1}(e^+)^{0.35}(\alpha/90^\circ)^m(P/e/10)^n \quad (12)$$

for square channel: $m = 0.35$

$$n = 0.1$$

for rectangular channels I and II:

$$m = 0$$

$$n = 0$$

The average Stanton number ($\overline{St}$) can be found by combining equations (10) to (12) for a given e/D , P/e , α , W/H , and Re .

In design consideration, correlations for the ribbed side wall Stanton number, $St(R)$, and the smooth side wall Stanton number, $St(s)$, may be useful. Assuming that equation (10) can be used to correlate the ribbed side wall heat transfer data by replacing $H(R)$ and $St(R)$ for H and St_r , one obtains

$$H(R) = R + (f_r / (2St(R)) - 1) / (f_r / 2)^{1/2} \quad (13)$$

Heat transfer correlation of the ribbed side wall shown in Figure 49 is

$$H(R) = 2.24 (W/H)^{0.1} (e^+)^{0.35} (\alpha/90^\circ)^m (P/e/10)^n \quad (14)$$

where the m and n values are the same as that in equation (12). The deviation of equation (14) is about $\pm 10\%$ for 90% of data shown in Figure 49. If $H(R)$, R , and f_r are known for a given e/D , P/e , α , W/H , and Re , the ribbed side wall Stanton number, $St(R)$, can be calculated by combining equations (13) and (14). After determining $\overline{St}$ and $St(R)$, the smooth side wall Stanton number $St(s)$ can be found by

$$St(s) = \overline{St} + (W/H) (\overline{St} - St(R)) \quad (15)$$

5.0 CONCLUSIONS AND RECOMMENDATIONS

1. The results obtained in the square channel of the present investigation confirm that was observed in the previous study [1]. In that, the heat transfer in the square channel with angled ribs ($\alpha = 30^\circ$ to 45°) is about 30% higher than that the transverse ribs ($\alpha = 90^\circ$) for a constant pumping power. However, the heat transfer in the rectangular channels I and II at $\alpha = 30^\circ$ - 45° is only about 5% higher than at $\alpha = 90^\circ$.

2. The highest heat transfer and pressure drop can be obtained at $\alpha = 60^\circ$ in the square channel, while the highest heat transfer and pressure drop are occurred at $\alpha = 90^\circ$ in the rectangular channel with a channel aspect ratio of 4 ($W/H = 4$). The heat transfer and pressure drop at $\alpha = 60^\circ$ are only slightly higher than that at $\alpha = 90^\circ$ in the rectangular channel with a channel aspect ratio of 2 ($W/H = 2$).

3. The heat transfer and friction decrease with decreasing the channel aspect ratio, W/H , from 4 to 2, to 1, to $1/2$, and to $1/4$, if the turbulence promoters are placed on the "W" side of the channel (i.e., the channel width).

4. For $\alpha = 90^\circ$, the local heat transfer after $X/D > 3$ becomes a periodic distribution in the streamwise direction in each channel. However, for $\alpha = 60^\circ$, 45° , or 30° , the local heat transfer varies in both the streamwise and the spanwise directions in each channel.

5. In the square channel the edgeline heat transfer on the ribbed side wall is higher than that the centerline at all rib angles, however, in the rectangular channels the edgeline heat transfer on the ribbed side wall is lower than that the centerline for the cases of angled ribs. Meanwhile, the edgeline heat transfer on the smooth side wall is always higher than that the centerline in all channels.

6. In the square channel, the RHS and LHS smooth wall temperatures are about the same for all rib angles. In the rectangular channel, the RHS smooth wall temperature is higher (30-40%) than that the LHS smooth wall when the ribs have angles ($\alpha = 60^\circ$, 45° , or 30°) to the flow. However, the RHS and LHS smooth wall temperatures are about the same for the $\alpha = 90^\circ$ and for the four sided smooth channel. It is recommended that this unexpected results need to be further investigated and confirmed.

7. The heat transfer and friction correlations are developed to account for rib spacing, rib angle, channel aspect ratio, and roughness Reynolds number.

8. It is suggested that the effect of rib angle for the rectangular channels with $W/H = 1/2$ and $1/4$ needs to be studied.

7.2 Tabulated Local Pressure Drop Data

Nomenclature:

1-4S	the smooth square channel
1-90/10	the square channel ($W/H = 2"/2"$) with $\alpha = 90^\circ$ and $P/e = 10$
2-60/20	the rectangular channel I ($W/H = 4"/2"$) with $\alpha = 60^\circ$ and $P/e = 20$
4-45/10	the rectangular channel II ($W/H = 4"/1"$) with $\alpha = 45^\circ$ and $P/e = 10$
1/2-90/10	the rectangular channel IA ($W/H = 2"/4"$) with $\alpha = 90^\circ$ and $P/e = 10$
1/4-90/20	the rectangular channel IIA ($W/H = 1"/4"$) with $\alpha = 90^\circ$ and $P/e = 20$
RU	along the upper ribbed wall
SL	along the left hand side smooth wall
f_{3-6}	average friction factor between pressure taps 3 and 6

7.3 Tabulated Local and Average Heat Transfer Data

Key:

RUN NUMBER = 77 HS10-00/00 to 81 HS 20-00/00
are for the smooth square channel ($W/H = 2"/2"$)

RUN NUMBER = 83 HR 10-90/10 to 118 HR 60-30/20
are for the rough square channel ($W/H = 2"/2"$)

RUN NUMBER = 70 HS 10-00/00 to 72 HS 60-00/00
are for the smooth rectangular channel I ($W/H = 4"/2"$)

RUN NUMBER = 22 HR 10-90/10 to 60 HR 60-30/20
are for the rough rectangular channel I ($W/H = 4"/2"$)

RUN NUMBER = 62 HR 10-90/10 to 68 HR 60-90/20
are for the rough rectangular channel IA ($W/H = 2"/4"$)

RUN NUMBER = 143 HS 10-00/00 to 145 HS 55-00/00
are for the smooth rectangular channel II ($W/H = 4"/1"$)

RUN NUMBER = 135 HR 10-90/10 to 176 HR 30-30/20
are for the rough rectangular channel II ($W/H = 4"/1"$)

RUN NUMBER = 179 HR 10-90/10 to 185 HR 60-90/20
are for the rough rectangular channel IIA ($W/H = 1"/4"$)

Nomenclature:

77 HS10-00/00	run number 77, heat transfer smooth channel, Reynolds number about 10,000
83 HR10-90/10	run number 83, heat transfer rough channel, Reynolds number about 10,000, $\alpha = 90^\circ$, $P/e = 10$
b/a	the same as W/H
TW	local wall temperature, $^\circ\text{F}$
R1,R2,R3	ribbed side wall along centerline, middleline, edgeline
S1,S2,S3	smooth side wall along centerline, middleline, edgeline
QGA(R)	net heat flux to air on the ribbed side wall
QGA(S)	net heat flux to air on the smooth side wall
NU(R)A	the average Nusselt number on the ribbed side wall
NU(S)A	the average Nusselt number on the smooth side wall
NU(AV)A	the average Nusselt number between the smooth side and the ribbed side walls (weighted by area)
4S	four-sided smooth channel
4R	four-sided rough channel
F	average friction factor in two opposite ribbed walls channel
ST	average Stanton number in two opposite ribbed walls channel
H(RB)	based on ribbed side wall only, the same as H(R)

16. Abstract Periodic rib turbulators have been used in advanced turbine cooling designs to enhance the internal heat transfer. The objective of the present project was to investigate the combined effects of the rib angle of attack and the channel aspect ratio on the local heat transfer and pressure drop in rectangular channels with two opposite ribbed walls for Reynolds number varied from 10,000 to 60,000. The channel aspect ratio (W/H) was varied from 1 to 2 to 4. The rib angle of attack (α) was varied from 90° to 60° to 45° to 30°. The highly detailed heat transfer coefficient distribution on both the smooth side and the ribbed side walls from the channel sharp entrance to the downstream region were measured. The results showed that, in the square channel, the heat transfer for the slant ribs ($\alpha = 30^\circ - 45^\circ$) was about 30 percent higher than that the transverse ribs ($\alpha = 90^\circ$) for a constant pumping power. However, in the rectangular channels (W/H = 2 and 4, ribs on W side), the heat transfer at $\alpha = 30^\circ - 45^\circ$ was only about 5 percent higher than that $\alpha = 90^\circ$. The results also showed that, in the square channel, the highest heat transfer was obtained at $\alpha = 60^\circ$ accompanying with the highest pressure drop, however, in the rectangular channel with W/H = 4, both the highest heat transfer and pressure drops were obtained at $\alpha = 90^\circ$. The average heat transfer and friction correlations were developed to account for rib spacing, rib angle, and channel aspect ratio over the range of roughness Reynolds number.
