Marine Corps Operations Analysis Group

ABSTRACT

Computerized adaptive test (CAT) and paper-and-pencil (PP) ASVAB scores are equated in several subpopulations to determine if racial minorities, females, nonhigh school graduates, or those lacking experience using computers would be at a disadvantage if CAT rather than PP scores were used for selection. Equating is generally independent of population group.

EXECUTIVE SUMMARY

The Department of Defense (DOD) plans to introduce a computerized version of the Armed Services Vocational Aptitude Battery (ASVAB). To maintain continuity of enlistment standards, scores on the computerized adaptive test (CAT) and the paper-and-pencil (PP) version of the test must be interchangeable, and the proportion of examinees who qualify for enlistment should be the same for both versions of the test. The process by which tests are made interchangeable is called "equating." If CAT scores do not equate to PP scores in a similar manner for males and females, for example, then one of these subpopulations could be at a disadvantage.

This research memorandum compares the equating of CAT to PP ASVAB subtests and aptitude composites in various subpopulations—gender, race, education, and computer experience. The data used were previously collected from a joint service sample of recruits. Examinees completed a questionnaire focusing on computer experience, ease of taking the CAT, and other "human factors" variables. The results generally indicate that subpopulation effects are small and not likely to be a problem during the Accelerated CAT-ASVAB Program (ACAP), when the CAT will be equated to the PP ASVAB. Findings are summarized below.

HUMAN FACTORS VARIABLES AND CAT

The correlations between test scores and questionnaire items, such as those reflecting examinees' experience with computers and difficulty with taking the CAT, were relatively independent of test modality. Those lacking experience with computers tended to have low scores on both the CAT and PP versions of the subtests.

SUBTEST LEVEL EQUATING

Equating was generally independent of gender, education, and computer experience. Subjectively meaningful differences were noted, however, with respect to race for the Numerical Operations (NO), Auto Information (AI), and Math Knowledge (MK) subtests. These differences, on the order of two to three ASVAB standard score points, are in such a direction as to favor minorities on the AI and MK subtests and to the disadvantage of minorities on the NO subtest. Since NO is part of the Armed Forces Qualification Test

(AFQT), minorities could also be disadvantaged by one to two AFQT percentile points.

APTITUDE COMPOSITES

Only two composites were studied. No meaningful subpopulation differences were observed for the Clerical (CL) score. Small differences were noted for the Electronics (EL) score that would tend to favor minorities.

INTRODUCTION

The Department of Defense (DOD) plans to introduce a computerized version of the Armed Services Vocational Aptitude Battery (ASVAB). Initial use of the DOD computerized adaptive test (CAT) is expected to begin soon in a few locations as the Accelerated CAT-ASVAB Program (ACAP). To maintain continuity of enlistment standards, scores on the CAT and the paper-and-pencil (PP) versions of the test must be interchangeable. One requisite for interchangeability is that the proportion of examinees who qualify for enlistment be the same for both versions of the test. Interchangeability implies that for a given PP test score, the equivalent CAT score is the same for different demographic groups.

The process by which the scores for one version of the test are interchanged or made equal to those for the other is referred to as "equating." Differences in the equating transformation for two subpopulations could lead to inequities in the selection process. For example, suppose a PP Armed Forces Qualification Test (AFQT) score of 21 is required for selection. If the equivalent CAT AFQT score for one subpopulation is 18, versus 21 for the overall population, then about 3 percent more individuals in the subpopulation tested with the CAT would not qualify for enlistment using the conversion table for the overall population. These same individuals, however, would qualify for enlistment with the PP test.

A previous study [1] examined subpopulation differences in equating CAT to PP scores for the Word Knowledge (WK) and Arithmetic Reasoning (AR) ASVAB subtests. The results indicated only small differences (no more than 1.5 ASVAB standard score points) in the equating for racial and educational subpopulations. This research memorandum expands on the previous work by examining the entire battery of subtests and by comparing equatings for additional subpopulations.

DATA

Using data collected in an earlier study, equipercentile equating procedures are used to equate CAT to PP ASVAB subtest scores in several subpopulations. The data used were collected as part of a joint armed services study to validate an early version of the CAT [2]. In that study, the CAT scores were validated against training grades. Both CAT and PP ASVAB

retest data (ASVAB forms 8, 9, or 10) were collected during initial skill training from about 7,000 recruits representing all of the armed services. The PP and CAT tests were administered back-to-back in counterbalanced order with a short intervening rest period. The CAT data include all subtests – General Science (GS), Arithmetic Reasoning (AR), Word Knowledge (WK), Paragraph Comprehension (PC), Numerical Operations (NO), Coding Speed (CS), Auto Information (AI), Shop Information (SI),¹ Math Knowledge (MK), Mechanical Comprehension (MC), and Electronics Information (EI). The PP data include only those retest scores required for selection into the recruit's military occupational specialty (MOS). This typically numbered from three to five tests per individual.

The CAT item pool consisted of about 200 items per subtest. The items were calibrated by the Navy Personnel Research and Development Center on a sample of about 2,500 applicants per item using LOGIST II [3].

The speeded tests, Numerical Operations (NO) and Coding Speed (CS), were administered by computer but conventionally scored as number correct during the original data collection. These subtests were then rescored as number correct per unit time; that is, $4 \times \text{number correct}/\text{testing time}$ (seconds). This scoring method is consistent with that to be used in the ACAP; it tends to increase the variability at the high end of the score continuum because some examinees finish the test before the time limit. Figures 1 and 2 show the relationship between number correct and the "rate" scores for the NO and CS subtests. The rate scores for the speeded tests are used later in the equating.

ANALYTICAL PROCEDURES

Factor Analysis of Questionnaire

Examinees were given a questionnaire on the ease of responding to the computerized test (see appendix A). One question asked if the examinee had ever used a computer before. About 40 percent of the 2,396 respondents answered "no" to this question. For the purpose of this study, those with no

1. In the CAT test, the PP subtest Auto and Shop Information (AS) is divided into the two subtests AI and SI. In the equating, both the CAT AI and SI subtests are equated to the PP AS subtest.

NOTE: Symbols indicate frequency of examinees per coordinate, where 1-Z represents 1-35, and * represents a frequency greater than 35.

FIG. 1: PLOT OF CAT NO SUBTEST: NUMBER CORRECT vs. NUMBER CORRECT / TIME

NOTE: Symbols indicate frequency of examinees per coordinate, where 1-2 represents 1-35, and * represents a frequency greater than 35.

FIG. 2: PLOT OF CAT CS SUBTEST: NUMBER CORRECT vs. NUMBER CORRECT / TIME

computer experience were used to define a "no computer experience" subpopulation.

Other subpopulations contrasted are gender, race, and education. The number of examinees from each subpopulation that had both CAT and PP ASVAB scores for the same subtests varied widely.

Responses to the questionnaire were used to determine "human factors" associated with the examinees' perceptions of the effects of the computer mode of test administration on test response. PP and CAT scores were then related to the factor scores to determine if perceptions about computer versus PP mode of test administration, called modality, were related to observed test scores.

Equating

Equipercntile equating, using analytic three-point moving average smoothing, was employed to equate the CAT to the PP tests. CAT scores, although originally estimated in the "theta" metric, were linearly transformed to a scale with a mean of 50 and a standard deviation of 10. These transformed scores were rounded to the nearest integer. This transformation was necessary for forming a discrete frequency distribution, as required by the computer software used to perform the equating. The result is a scale with unit intervals corresponding to one-tenth of a standard deviation of the original theta metric. After equating, the CAT scores were linearly transformed back to their original metric of mean zero and unit variance.

Aptitude Composites

Two aptitude composites, Electronics (EL) and Clerical (CL), were constructed from the CAT and PP data. These were chosen on the basis of adequacy of sample sizes in the available subpopulations. The CAT composites were built from the sum of equated subtest scores scaled to the 1980 reference population; that is, the CAT subtest scores were first equated to the appropriate PP subtest scores, then, these equated subtest scores were added and linearly transformed to the 1980 metric. The composites constructed in this manner were:

$$EL = MK + EI + GS + AR$$

$$CL = WK + PC + NO + CS .$$

RESULTS

Factor Analysis of Questionnaire

The questionnaire was composed of 32 items. Responses were quantified as shown in appendix A. The correlations were then factored by the Principal Components method, using an iterative procedure to estimate communalities [4]. Table 1 shows the resulting communalities. The communalities are conservative estimates of the reliability of the responses to the questionnaire.

Five interpretable factors, accounting for 32 percent of the total variance, emerged from the analysis. These factors were orthogonally rotated to produce the factor pattern shown in table 1. (Note that only those factor loadings greater than 0.25 are shown.)

The first factor, named "ease of use," is dominated by such items as "enjoyed taking the test on a computer" and "made corrections easily." Not enjoying the computer testing mode was associated with being uncomfortable with the rate of item presentation, not understanding the instructions for taking the different subtests and difficulty in correcting responses. Of particular interest is whether such difficulties in taking the CAT were reflected in the test scores. This issue is examined in detail later.

The second factor has to do with difficulty in reading the visual display. (See questions 7 and 8 in appendix A.) The magnitude of the factor loadings suggests that difficulty in reading the display was due to all the reasons enumerated in question 8 of appendix A (size of letters, font, spacing, contrast, and glare). About 10 percent of the respondents reported having difficulty with the display.

The third factor could be labeled an "annoyance factor." The items defining this factor have to do with the ease of using the keyboard and the noise level of the computer. Responses to these items were also related to feeling "uneasy" with the test and inability to change answers.

The fourth factor was composed of two similiarly worded items (questions 11 and 27) concerning eyestrain. Failure of these items to load on the "visual display" factor suggests that having difficulty with the visual display does not always lead to eyestrain.

a. See appendix A for the meanings of these mneumonics.

The last factor concerns the experience of examinees in using computers. Those who had not used a computer before indicated that they had never used a typewriter and had greater need for both the proctor's and the computer's instructions in order to take the test. Those with computer experience did not need help.

The effect these factors may have had on test scores is explored by forming factor scores from the questionnaire responses and correlating them to both the CAT and the PP ASVAB scores. Factor scores were formed as a weighted composite of the items comprising the factor. The weights were determined by a regression method that uses the questionnaire item inter-correlations to represent correlations among items, and the factor loadings to represent correlations between each item and the hypothetical factor [4]. A significant CAT-factor score correlation, in the absence of a PP-factor score correlation, would indicate the presence of a modality of test administration effect. Significant correlations for both CAT and PP scores with the factors would indicate that ability, as measured by the ASVAB subtest, is the determinant of the factor. For example, suppose a significant positive correlation is observed between "computer experience" and the CAT score for a particular subtest. If the PP score also correlated positively with the experience factor, the result could be interpreted to indicate that more able examinees (as measured by the subtest) tend to have more experience than less able examinees. In the absence of a correlation between the factor and the PP score, the interpretation would be that lack of experience with computers leads to lower CAT scores, but does not effect PP scores.

Table 2 shows the correlations between the five factor scores and the CAT and PP ASVAB subtest scores. Mean test scores for those with no computer experience and those with experience are also shown. The correlations between a given factor and ASVAB test score tends to be about the same for CAT and PP scores. For the most part, the correlations tend to be low.

There is no evidence of a modality effect associated with experience with computers. The differences in mean PP and CAT subtest scores across prior experience groups was, in most cases, statistically significant and except for the AS and EI group, in favor of those with computer experience. In the absence of a modality effect, this indicates that those having used computers prior to taking the CAT tend to be more able examinees. What remains to be determined is whether CAT equates to PP in a similar manner for those with and without prior computer experience.

a. $p < .01$.

b. PP AS test scores used as reference test for CAT AI and SI scores.

Equating

The sample sizes available for equating CAT to PP for each subtest within a subpopulation are shown in table 3. Note that some of the samples are quite small (less than 200 cases). Results from equating these small samples should be viewed with caution.

Subtest Level

The results of equating CAT to PP at the subtest level are presented graphically. Each graph contrasts a single subpopulation, for example, males versus females. (Corresponding equating tables are shown in appendix B.) Differences in the equating curves tend to appear at the low end of the score continuum. These differences, however, are associated with score intervals typically having fewer than 10 observations. Subjective comparisons of the curves are made.

Experience

Figure 3 contrasts the subtest level equatings for examinees with and without computer experience. Only one subtest, AR, shows that computer experience had any effect. Examinees with no experience and with PP scores below 50 tend to score about 0.2 theta-scale units lower than those with computer experience.

Gender

Contrasts for males and females are shown in figure 4. Little evidence of a gender effect is evident from these data. Note, however, that most of the female samples (6 out of 11) are small.

Race

Figure 5 contrasts equatings of Caucasians with minorities (non-Caucasians). Four of the subtests show a consistent racial bias. Minorities tend to have higher CAT scores, for a given PP score, than Caucasians on the AI and MK subtests. Minorities, however, tend to score lower on the CAT NO subtest, for a given PP NO score, than do Caucasians.

a. Less than 200 cases.

NOTE: Sample sizes were less than 200 for those without computer experience taking the GS, MK, and EI subtests.

**FIG. 3: EQUIPERCENTILE EQUATING BY SUBPOPULATIONS
(COMPUTER EXPERIENCE)**

NOTE: Sample sizes were less than 200 for females taking the GS, AR, AI, MK, EI, and SI subtests.

FIG. 4: EQUIPERCENTILE EQUATING BY SUBPOPULATIONS (GENDER)

FIG. 5: EQUIPERCENTILE EQUATING BY SUBPOPULATIONS (RACE)

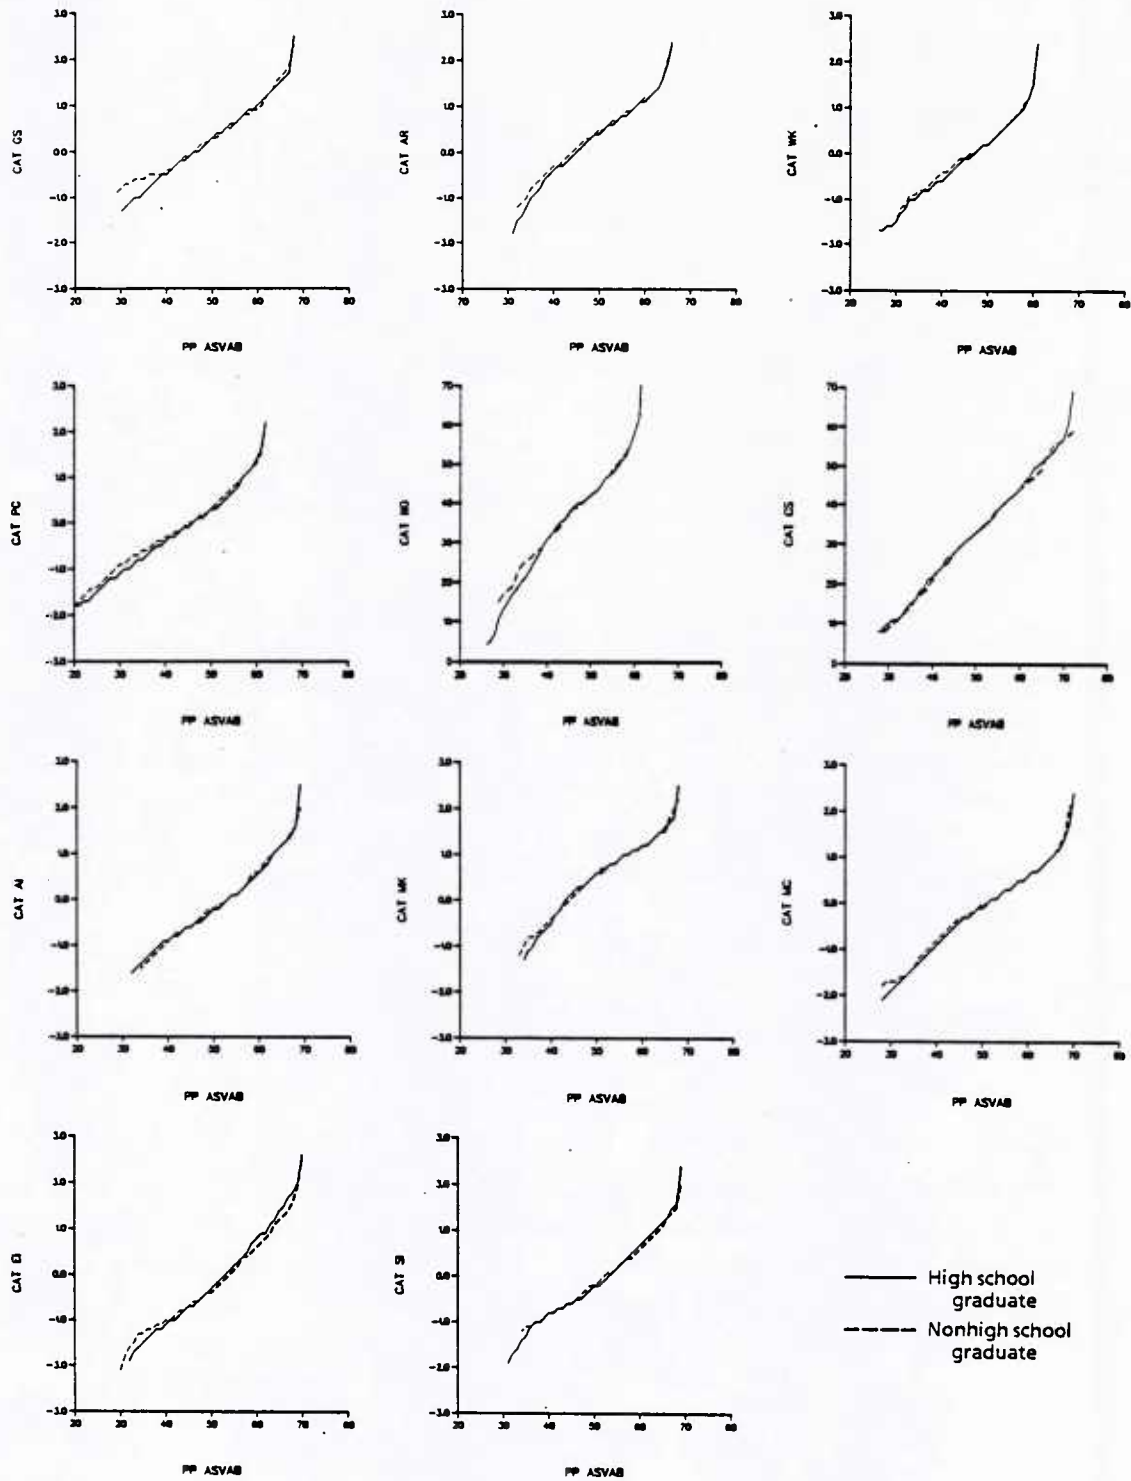

FIG. 6: EQUIPERCENTILE EQUATING BY SUBPOPULATIONS (EDUCATION)

Education

Figure 6 contrasts high school graduates with nongraduates. Small differences are seen for the AR and PC subsets. For these subtests, nongraduates tend to score somewhat higher on CAT (0.1 to 0.2 scale points).

Aptitude Composites

Small samples permitted the construction of only two aptitude composites, Clerical (CL) and Electrical (EL). The equating of the CAT and PP composites are discussed below.

CL

The equating of the CAT to the PP composite for males and females is shown in the upper panel of figure 7. The lower panel of the figure shows the proportion of each subpopulation whose CAT scores equated to a given PP composite score. Differences in the male and female "curves" represents the selection bias that might occur using CAT scores, at any given PP score. Because the equating data were based on recruits selected on the basis of their PP scores, scores below the cutoff point were not observed. Only small differences in the region above a composite score of 120 are observed. These are of no practical significance.

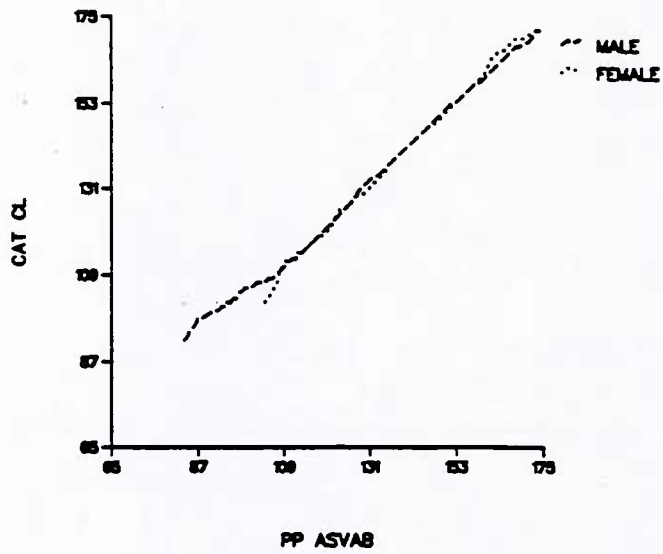

Figure 8 shows the equating of CL for Caucasians and minorities. No large or consistent differences are observed.

EL

The data shown in figure 9 compare the equating of the EL composite for Caucasians and minorities, based on a small sample of minorities (163). The results suggest that minorities would benefit from being tested on CAT ASVAB for selection by EL. For example, at a cutting score of 90, about 8 percent more minorities would be selected with a CAT than with a PP test.

SUMMARY AND CONCLUSIONS

This analysis compared the equating of CAT to PP ASVAB subtests and aptitude composites in various subpopulations. Equating was generally

EQUITY COMPARISON
(CL COMPOSITE)

KS Two Sample (Chi Square) Statistic = 3.983

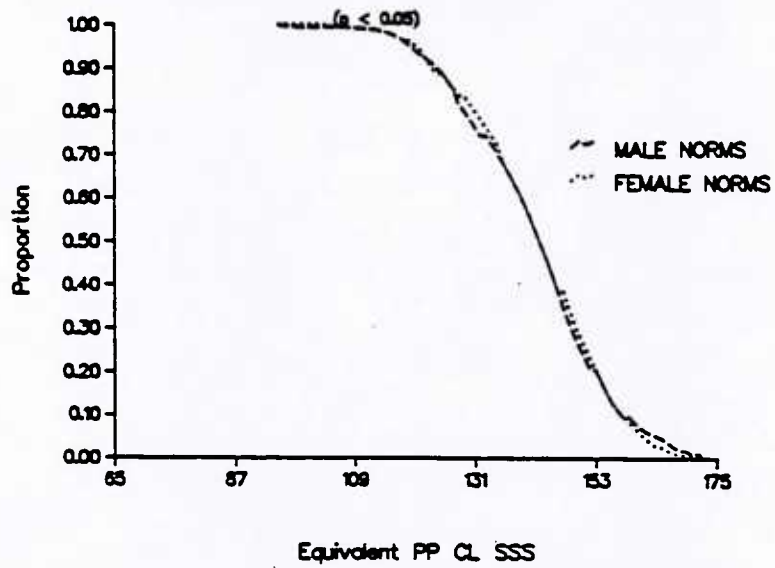

FIG. 7: CL COMPOSITE BY GENDER

EQUITY COMPARISON
(CL COMPOSITE)

KS Two Sample (Chi Square) Statistic = 2.282

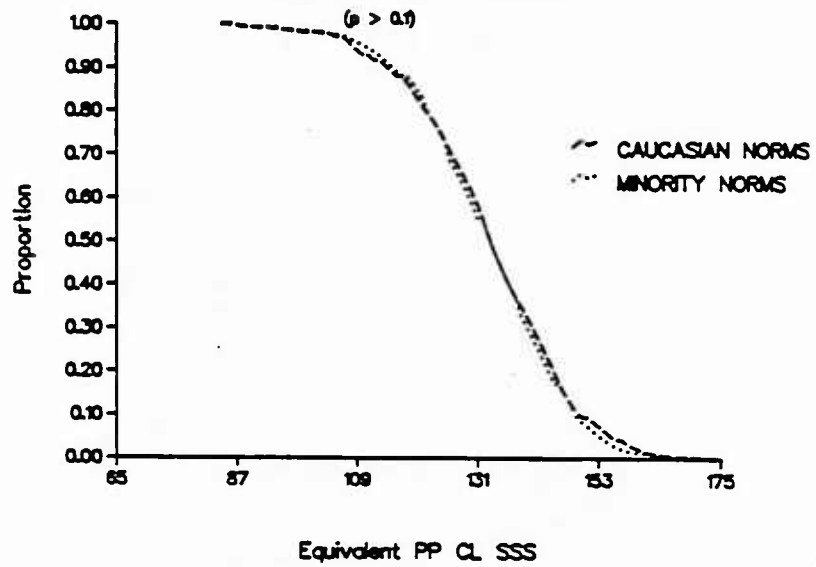

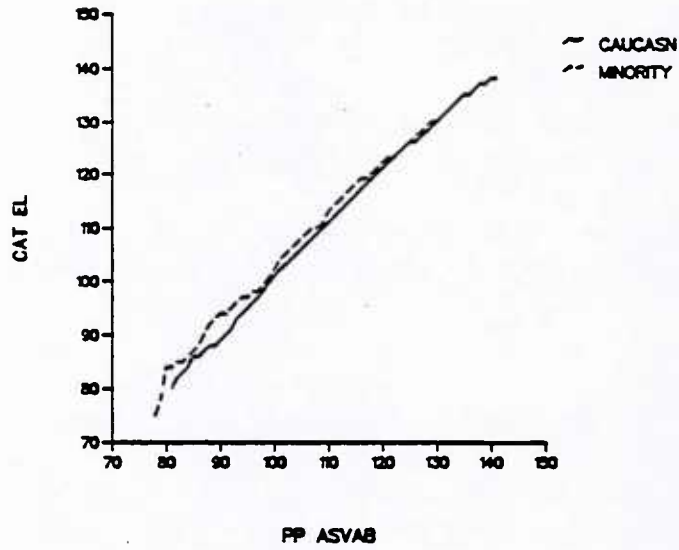

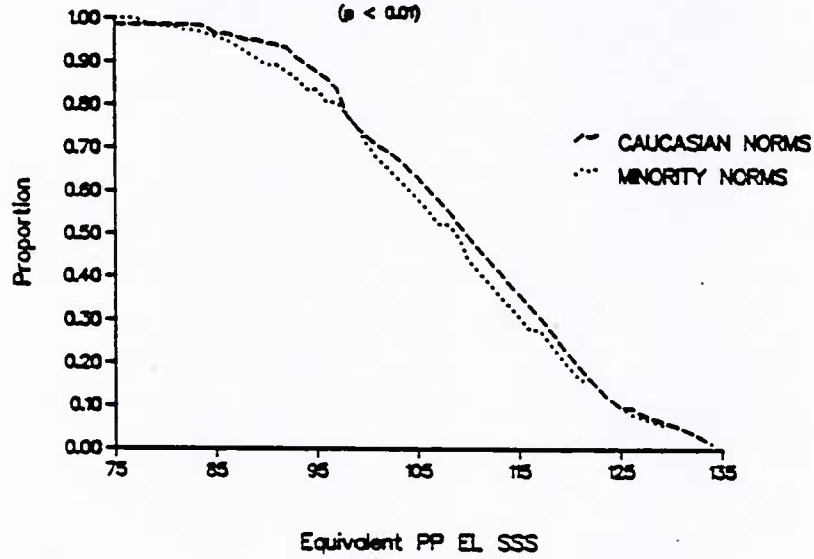

FIG. 8: CL COMPOSITE BY RACE

EQUITY COMPARISON
(EL COMPOSITE)

KS Two Sample (Chi Square) Statistic = 8.237

(p < 0.01)

NOTE: Sample size was less than 200 for minorities.

FIG. 9: EL COMPOSITE BY RACE

independent of population group. Subjectively meaningful differences are noted, however, with respect to race for the NO, AI, and MK subsets. These differences, on the order of 2 to 3 ASVAB standard score points, are in such a direction as to favor minorities on the AI and MK subsets and to the disadvantage of minorities on the NO subset. Since NO is part of the AFQT, minorities could also be disadvantaged by 1 to 2 AFQT percentile points.

Two composites were also studied. No meaningful subpopulation differences were observed for CL. Small differences were noted for EL that would tend to favor minorities.

These results imply that subpopulation differences are not likely to be a major concern in the forthcoming ACAP testing program where CAT and PP scores will be equated. This suggests that the ACAP equating sample need not be precisely stratified along the dimensions represented by the subpopulation groups used here. The results also suggest that special training for examinees lacking experience with computers will not be necessary.

APPENDIX A
CAT QUESTIONNAIRE

APPENDIX A

CAT QUESTIONNAIRE

The items contained in the questionnaire given to CAT examinees, along with mneumonics used as labels in table 1 of the main text, and scale values applied for quantifying responses are contained in this appendix.

QUESTIONNAIRE

BEFORE YOU LEAVE...

The computerized test you have just taken is an experimental test which will be administered to several thousand recruits. We are interested in examinees' reactions to the test, and their opinions of computerized testing. Your answers to this questionnaire will provide a valuable contribution in the evaluation of this testing process.

Some of the questions below will ask you for information. Others will ask you to state whether you agree with a statement or how often things happen. Please read each question carefully and follow the instructions for each set of questions.

CIRCLE THE APPROPRIATE ANSWERS FOR THE QUESTIONS BELOW.

Mnemonic	Scale value	Item
USED C		1. I have used a computer ...
	1	A. Never before
	2	B. Once or twice
	3	C. Occasionally
	4	D. Frequently
USED T		2. I have used a typewriter ...
	1	A. Never before
	2	B. Once or twice
	3	C. Occasionally
	4	D. Frequently
PASSIST		3. If you needed assistance, was the proctor helpful?
	1	A. Yes
	3	B. No
	2	C. I did not need assistance

SCNRATE		4. The test questions appeared on the screen . . .
	1	A. Too fast
	3	B. Too slow
	2	C. At about the right speed
CVSPPD		5. Overall, the computerized test was . . .
	1	A. More difficult than the paper and pencil tests
	3	B. Easier than the paper and pencil test
	2	C. About as difficult as the paper and pencil test
CVSPPS		6. The computerized test was . . .
	1	A. Faster than the paper and pencil test
	3	B. Slower than the paper and pencil test
	2	C. About the same as the paper and pencil test
READQ		7. I could read the test questions on the screen . . .
	1	A. With great difficulty
	2	B. With some difficulty
	3	C. Easily
	4	D. Very easily
		8. <i>If you had difficulty</i> in reading the test questions or viewing the screen, please circle all items below which relate to those difficulties. Otherwise, leave blank.
GLARE	0,1	A. Glare on the screen
SPACE	0,1	B. Not enough space between lines
TYPE	0,1	C. Difficulty in reading the type of lettering
LAYOUT	0,1	D. Layout of the questions on the screen
CONTRAST	0,1	E. Not enough contrast between screen and letters
SIZE	0,1	F. Size of letters was too small
CONFUS		9. The test was confusing . . .
	0	A. Only during the instructions
	0	B. Only when answering questions
	0	C. During both instructions and answering questions
	1	D. Not at all

10. Please list any area of the test which was confusing.

not used

TIRED1

11. My eyes felt tired . . .
- 1 A. Frequently
 - 2 B. Occasionally
 - 3 C. Once or twice
 - 4 D. Not at all

FOR THE QUESTIONS BELOW, CIRCLE THE ANSWER THAT COMES CLOSEST TO MATCHING YOUR JUDGMENT OR OPINION.

INSCLR

12. How clear do you feel the computerized instructions were?
- 1 A. Very clear – I had no trouble at all with them
 - 2 B. Clear enough, in general – but could be improved
 - 3 C. Unclear in places or in part
 - 4 D. Very unclear and confusing

RUSHED

13. Did you have enough time to give your answers?
- 1 A. I didn't feel rushed or pressured at all
 - 2 B. I felt a little rushed and could have used more time
 - 3 C. I felt rushed and pressed for time

EASCOR

14. Could you make corrections easily enough?
- 1 A. The correction method is simple – I had no problems
 - 2 B. I had some problems – in some cases I wanted to change my answer after it was too late
 - 3 C. I had serious problems – in many cases I wanted to change my answer after it was too late

DIFFLEV

15. What is your opinion of the difficulty level of the questions?

- 1 A. They were too difficult
- 2 B. They were about right
- 3 C. They were too easy

THE QUESTIONS BELOW ASK WHETHER YOU AGREE, DISAGREE, OR ARE UNDECIDED ABOUT CERTAIN STATEMENTS. CIRCLE THE RESPONSE WHICH MOST CLOSELY REPRESENTS YOUR OPINION.

USDP

16. I understood the *proctor's* instructions and introduction to the test.

- 1 A. Agree
- 3 B. Disagree
- 2 C. Undecided

NEEDPI

17. I did not need the *proctor's* instructions in order to take the test.

- 1 A. Agree
- 3 B. Disagree
- 2 C. Undecided

NEEDCI

18. I did not need the *computerized* instructions in order to take the test.

- 1 A. Agree
- 3 B. Disagree
- 2 C. Undecided

LOCKEY

19. I had difficulty in *locating* the proper keys on the keyboard.

- 1 A. Agree
- 3 B. Disagree
- 2 C. Undecided

PRESKEY

20. I had difficulty in *pressing* the right keys.

- 1 A. Agree
- 3 B. Disagree
- 2 C. Undecided

- UNEASY
- 1
3
2
21. I felt uneasy about taking the test on a computer.
A. Agree
B. Disagree
C. Undecided
- NOISE
- 1
3
2
22. The noise from the computer bothered me while I was taking the test.
A. Agree
B. Disagree
C. Undecided
- UNSTDST
- 1
3
2
23. On the speeded tests, it was easy to understand how to answer the questions.
A. Agree
B. Disagree
C. Undecided
- IMPERS
- 1
3
2
24. Computerized testing is more impersonal than paper and pencil testing.
A. Agree
B. Disagree
C. Undecided
- ENJOY
- 1
3
2
25. I enjoyed taking the test on a computer.
A. Agree
B. Disagree
C. Undecided
- NOTCH
- 1
3
2
26. I was bothered by not being able to change my answers at the end of each section of the test.
A. Agree
B. Disagree
C. Undecided
- TIRED2
- 1
3
2
27. My eyes were tired by the end of the test.
A. Agree
B. Disagree
C. Undecided

FOR THE QUESTION BELOW, PLEASE FILL IN THE
INFORMATION REQUESTED.

NOTIMES

1. Approximately how many times during the test did you want to skip questions and come back to them?

_____ times

APPENDIX B
EQUATING TABLES

APPENDIX B

EQUATING TABLES

CAT scores, equivalent to PP ASVAB standard subtest scores (SS), in the 1980 metric are shown for the CAT subtests for various subpopulations. The CAT scores are linearly transformed, using an additive constant of 50, and a multiplier of 10. This results in a range of scale values of 20-80, which corresponds to a range of ± 3 in the original theta metric.
