19 ABSTRACT (Continue on reverse if necessary and identify by block number) Software metrics is in its infancy, is a very new field and there are many scientists and educators who would choose to keep it that way. Software metrics is held in low esteem by many software engineers. There is much debate and argument about what a good metric should do, how it should work, and what it should produce for the user. Yet with the cost of software rising, it is becoming more and more critical for future cost control and expense management that some automatic metric tool be implemented. Interest is growing, as evidenced by the Department of Defense expressing a strong interest in the development of an effective and reliable metric tool. It is no doubt that if this can be accomplished the automated software metric would be a valuable asset to the software engineering effort.

ABSTRACT

Software engineers in general, and the Department of Defense in particular, are looking for good software metrics to aid in software development. Maurice Halstead developed the theory of Software Science which includes the relation between program complexity and program length. Halstead's length metric deals with the properties of an algorithm that can be measured, either directly or indirectly, statically or dynamically, and with the relationships among these properties. A system has been developed which implements Halstead's length metric. This system, which is written in Ada, takes Ada programs as input, and outputs the length metric complexity analysis. Finally, recommendations for future work in this area are made.

I. INTRODUCTION AND BACKGROUND

A. CONCERNS

With computer software programs getting larger and larger all the time, the search is on for accurate and dependable aids for the developer to increase the productivity and efficiency of software engineering efforts. New tools and new methodologies are being sought in the effort to alleviate the "software crisis". This crisis, stated specifically, is that software is being delivered late, over budget, specifications are not being met, modifications are difficult and expensive, unresponsive to user needs, and unreliable.

Recently, it was reported that software costs are growing at the rate of 15% per year while productivity is increasing at less than 3% [Ref. 1: p.15]. Barry Boehm, a leading computer expert, asserted more than 10 years ago that, in the military application area, the cost of software was expected to reach about 80% of the total computer system budget by the year 1985 [Ref. 2: p.1]. His assertion now seems valid [Ref. 3]. Furthermore it appears that up to 60% of the total software budget for all organizations using computers is being devoted to maintenance [Ref. 2: p.2]. The Office of Naval Research and other Defense Research agencies are aware of these increasing costs. They are also acutely aware of the lack of quantitative measurement techniques which are desperately needed for assessing the quality and reliability of software as well as for the prediction and measurement of software production [Ref. 1: p.14]. Further evidence of this universal concern comes from a General Accounting Office report of June 78 on managing weapons systems. It stated that there exists no Department of Defense performance criteria to measure software quality and to establish a basis for its acceptance or rejection [Ref. 1: p.15]. The Secretary of Defense's response was brief and candid,

We concur. We regret and underscore the importance of the need. The Department of Defense will quickly embrace such measures when they are available.

The current Office of Naval Research (ONR) initiative to focus on software measurement is a result of the need for such metrics and the high level of interest that

the Secretary of Defense brings to bear. The ONR initiatives, stated specifically, are: developing indices of merit that can support quantitative comparisons and evaluations; designing a philosophical framework for understanding and defining software measurement; and focusing the attention of the scientific community on computer software. [Ref. 1: p.15].

B. AVAILABLE METRICS

Software metrics are often classified as either process metrics or product metrics, and are applied to either the development process or the software product being developed [Ref. 2: p.19]. Process metrics include resource metrics, such as the experience of programmers, and the cost of development and maintenance. Examples of metrics for the levels of personnel experience are the number of years that a team has been using a programming language, the number of years that a programmer has been with the organization, the number of years that a programmer has been associated with a programming team, and the number of years of experience constructing similar software [Ref. 2: p.19]. Other factors considered in process metric measurement are development techniques (the use of top-down or bottom-up development techniques, and structured programming), supervisory techniques (such as type of team organization and number of communication paths), and resources (human, computer, time schedule, and so on) [Ref. 2: p.20]. Product metrics, on the other hand, are a measure of the software product. Product metrics include the size of the product (such as number of lines of code or some count of tokens in the program), the logic structure complexity (such as flow of control, depth of nesting, or recursion), the data structure complexity (such as the number of variables used), the function (such as type of software: business, scientific, systems, and so on), and combinations of these [Ref. 2: p.20].

The emphasis in this thesis will be on product metrics to the total exclusion of process metric issues. We are interested in analyzing the static program, or product, in our effort to provide an automated tool.

There are a variety of different quantitative software metrics in use today. In an important paper by Boehm [Ref. 4], an attempt is made to define software quality in terms of some high level characteristics such as reliability, portability, efficiency, human engineering, testability, understandability, and modifiability. If we can define these characteristics, noting that a precise subjective definition is difficult to achieve,

and measure these characteristics with some precision, we could strive to maximize each of these characteristics [Ref. 2: p.7]. There are some difficulties here. First, some of the characteristics are potentially contradictory. For example, improvements in portability and understandability usually result in decreased efficiency [Ref. 2: p.7]. Secondly, there are significant cost/benefit tradeoffs. For example, the cost of producing highly reliable code may be several times more costly, in terms of time and/or money, than for less reliable code [Ref. 2: p.7].

The measurement of software complexity is receiving increased attention in recent years. Complexity has been a loosely defined term but Bill Curtis defined complexity to be a characteristic of the software interface which influences the resources another system will expend or commit while interfacing with the software [Ref. 5]. Two separate and distinct focuses have emerged in studying software complexity: computational and psychological complexity [Ref. 1: p.208]. Computational complexity relies on the formal mathematical analysis of such problems as algorithm efficiency and use of machine resources. In contrast, the empirical study of psychological complexity has emerged from the understanding that software development and maintenance are largely human activities. Psychological complexity is concerned with the characteristics of software which affect programmer performance [Ref. 1: p.208]. This thesis will focus entirely on program complexity in an effort to provide a representative metric from selected quantitative measures.

There are a variety of complexity metrics available and we will briefly highlight a few of them. A number of metrics having a base in graph theory have been proposed to measure complexity from control flow [Ref. 1: p.210]. Thomas McCabe devised one of the better known complexity metrics in relation to the decision structure of a program [Ref. 6]. McCabe argues that his metric assesses the difficulty of testing a program, since it is a representation of the control paths that must be exercised during testing [Ref. 1: p.210]. Victor Basili and Robert Reiter [Ref. 7], have developed different counting methods for computing cyclomatic complexity by counting rules for case statements and compound predicates [Ref. 1: p.210]. Definitive data on the most effective counting rules has yet to be presented. The best known and most thoroughly studied of the composite measures of complexity is Halstead's theory of Software Science [Ref. 1: p.211]. In 1972, Maurice Halstead argued that algorithms have measurable characteristics analogous to physical laws. We will focus this thesis on Halstead's theory as the representative metric we implement. We will first look at Halstead's theory.

C. HALSTEAD

Halstead's software science theory applies the scientific method to the properties and structure of computer programs. It attempts to provide precise, objective measures of the complexity of existing software, which is then used to predict the length of the programs [Ref. 9: p.3]. Numerous statistical studies have shown very high correlations between the theory's predictions and actual program measures such as mean number of bugs [Ref. 8: p.85]. Halstead defined four basic measures:

1. $n1$: The number of distinct operators appearing in a program.
2. $n2$: The number of distinct operands appearing in a program.
3. $N1$: The total number of occurrences of the operators in a program.
4. $N2$: The total number of occurrences of the operands in a program.

Halstead defined the size of the *vocabulary* to be the operators plus the operands as in Equation 1.1.

$$n = n1 + n2 \quad (\text{eqn 1.1})$$

Halstead's theory [Ref. 8: p.11], says that actual program length can be calculated by adding the total number of operand references with the total number of operator references as in Equation 1.2.

$$N = N1 + N2 \quad (\text{eqn 1.2})$$

Halstead, using information theory, computes the theoretical length or predicted length as in Equation 1.3.

$$N = n1 * (\log_2 (n1)) + n2 * (\log_2 (n2)) \quad (\text{eqn 1.3})$$

Halstead also speaks of program volume as in Equation 1.4.

$$V = N \log_2 n \quad (\text{eqn 1.4})$$

The intuition is simple. For each of the N elements of a program, $\log_2 (n)$ bits must be specified to choose one of the operators or operands for that element, thus, volume (V) measures the number of bits required to specify a program [Ref. 8: p.19].

Halstead also hypothesized a conservation law between the level of abstraction and the volume. The level is defined as the ratio of potential to actual volume where the potential volume is the volume of the most compact (highest-level) representation of the algorithm [Ref. 8: p.25]. Effort, another variable that Halstead suggests, is a measure of the mental effort required to create a program. He describes effort as the ratio of volume to program level which implies that programming difficulty increases as the volume of the program increases, and decreases as program level increases [Ref. 8: p.47]. Halstead hypothesized that programming Time (T) should be directly proportional to the Effort (E) in a program, as in Equation 1.5.

$$T = E / S \quad (\text{eqn 1.5})$$

The constant S represents the Speed of a programmer, i.e., the number of mental discriminations per second of which he/she is capable [Ref. 3: p.48].

We agree with Alan Perlis, that regardless of the empirical support for many of Halstead's predictions, the theoretical basis for his metrics needs considerable attention [Ref. 1: p.214]. Halstead, more than other researchers, tried to integrate theory from both computer science and psychology. Unfortunately, some of the psychological assumptions underlying his work are difficult to justify for the phenomena to which he applied them [Ref. 1: p.214]. Perlis states, and again we agree, that computer scientists would do well to purge from their memories the magic number 7 ± 2 , and the Stroud number of 18 mental discriminations per second. These numbers describe cognitive processes related to the perception or retention of simple stimuli, rather than the complex information processing tasks involved in programming [Ref. 1: p.214]. Broadbent [Ref. 10], argues that for complicated tasks (such as understanding a program) the magic number is substantially less than seven. For the above reasons, this thesis will focus on the actual count of the operators and operands and will totally exclude any discussion about Halstead's other hypothesis.

D. OUR METRIC

The metric we have implemented will take, as input, an Ada program and analyze this program with respect to Halstead's length hypothesis. To properly carry out this task, the input program must be decomposed into its most basic lexical elements, and then parsed to ensure that the program is syntactically correct. As the structure of the

program is being validated the data needed for metric implementation is collected and stored for later analysis. We have designed a generic front-end for this metric tool which means other metrics can be added at a later date, thus giving the program the ability to be expanded and provide a wider range of data. We will cover each of these front-end sections in detail and describe how and why our metric operates.

II. DEVELOPING AN ADA GRAMMAR

A. INTRODUCTION

The *grammar* of a language specifies the syntax of the language and is used to help guide the translation of programs. A grammar naturally describes the hierarchical structure of many programming language constructs [Ref. 11: p.26]. A grammar has four components:

1. A set of tokens, known as *terminal* symbols.
2. A set of *nonterminals*.
3. A set of *productions* which consists of a nonterminal, an arrow, and a sequence of terminals and/or nonterminals.
4. A designation of one of the nonterminals as the *start* symbol.

Grammars are classified by many characteristics, and different parsing techniques are more or less effective on a particular class of grammar. The most efficient methods of parsing, *top-down* and *bottom-up*, which we will cover in chapter four, work only on certain subclasses of grammars. Several of these subclasses, such as the **LL** and **LR** grammars, are expressive enough to describe most syntactic constructs in programming languages [Ref. 11: p.160]. Parsers implemented by hand often work with **LL** grammars and parsers for the larger class of **LR** grammars are usually constructed by automated tools. The first **L** in **LL** stands for scanning the input from left-to-right, the second **L** for producing a leftmost derivation. Conversely the **L** in **LR** is again for left-to-right scanning of the input, the **R** for constructing a rightmost derivation in reverse [Ref. 11: p.215]. A grammar that is **LL(1)** can be deterministically parsed with a top down left to right scan by using only one token lookahead. Therefore, an **LL(1)** grammar has a parsing table with no multiply-defined entries. If the present parsing table has multidefined entries an attempt can be made to transform the grammar by eliminating all left recursion and left factoring whenever possible [Ref. 11: p.192]. There are some grammars for which no amount of alteration will yield an **LL(1)** grammar. Eliminating left recursion and then left factoring is easy to do but may make the resulting grammar hard to read and difficult to use for translation purposes. These procedures are covered in the next section.

A grammar generates strings by beginning with the start symbol and repeatedly replacing a nonterminal by the right side of a production for that nonterminal. The

terminal strings that can be derived from the start symbol form the *language* defined by the grammar [Ref. 11: p.28].

B. GRAMMAR FOR THE ADA LANGUAGE

Ada is a very large language consequently the grammar for this language is also very large. We chose to use a top-down, recursive-descent parser, which will be covered in greater detail in chapter four, as our method of analyzing our input program. We used the Ada language as defined in the Ada Language Reference Manual (LRM) [Ref. 12]. Our first step was to translate the Ada language from the Backus-Naur Form given in the Ada Language Reference Manual. In translating this grammar, which is not LL(1), into an LL(1)-like grammar, it was necessary to *massage* the language description given in the manual. Massaging is the process of removing all left recursion and then left factoring. Left recursion is when the leftmost symbol on the right side of a production is the same as the nonterminal on the left side of the production. Left recursion must be eliminated for this top-down, recursive descent parser to alleviate the possibility of infinite looping. It must be remembered, this process does not guarantee that the transformed language will be LL(1). However, we must be sure to perform transformations that lead to a grammar for the same language. The remainder of this chapter is devoted to the discussion and explanation of how we massaged the grammar. The complete grammar used by our parser can be found in Appendix A. Our translation key has terminal symbols as lowercase letters, non-terminal symbols as uppercase letters, and bold-faced symbols to indicate the meta-symbols of our grammar.

Once the initial grammar is expressed in our meta-symbology, the next step is to remove all left recursion. Since the BNF form in the LRM showed no left recursion, it appeared that this step would not be required. However, there was one case of left recursion that was not apparent until several substitutions of the productions had been made. This case involved the production rules for NAME, INDEXED_COMPONENT, SLICE, SELECTED_COMPONENT, ATTRIBUTE, and PREFIX. The production rules, when taken directly from the LRM, appear as the follows:

```
NAME --> identifier
      --> character_literal
      --> string_literal
      --> INDEX_COMPONENT
```

```

--> SLICE
--> SELECTED_COMPONENT
--> ATTRIBUTE

INDEXED_COMPONENT --> PREFIX (EXPRESSION)

SLICE --> PREFIX (DISCRETE_RANGE)

SELECTED_COMPONENT --> PREFIX.SELECTOR

ATTRIBUTE --> PREFIX'ATTRIBUTE_DESIGNATOR

PREFIX --> NAME
--> FUNCTION_CALL

```

When starting with NAME and substituting in the productions, the left recursion becomes readily apparent. For example:

```
NAME --> SLICE --> PREFIX(DISCRETE_RANGE) ==> NAME(DISCRETE_RANGE)
```

We see that the following production exists:

```
NAME --> NAME (EXPRESSION)
```

Several other productions, left recursive on NAME, can be generated using the other rules listed above.

Now that left recursion does exist, we expanded out the productions listed above (using the same technique previously demonstrated) and combined them all as production rules for NAME. The production rules for INDEXED_COMPONENT, SLICE, SELECTED_COMPONENT, and ATTRIBUTE were incorporated into NAME so they were removed from our grammar. The final set of production rules for NAME can be found in Appendix A.

The third step in massaging our grammar is left factoring. Our parser could not function with one token lookahead if left factoring were possible. Left factoring is a grammar transformation which uses the basic idea that if it is not clear which of two alternative productions to use to expand a nonterminal, it may be possible to rewrite the productions to defer the decision until we have enough of the input to make the correct decision. To demonstrate this procedure, we will show the left factoring used on the productions for RELATION. Taken directly from the LRM the production rules for RELATION are as follows:

```

RELATION --> SIMPLE_EXPRESSION
        --> SIMPLE_EXPRESSION RELATIONAL_OPERATOR SIMPLE_EXPRESSION
        --> SIMPLE_EXPRESSION in RANGES
        --> SIMPLE_EXPRESSION not in RANGES
        --> SIMPLE_EXPRESSION in TYPE_MARK
        --> SIMPLE_EXPRESSION not in TYPE_MARK

```

Applying the rule of left factoring, a new nonterminal, SIMPLE_EXPRESSION_TAIL, has been added to the grammar. The production rules for RELATION and SIMPLE_EXPRESSION_TAIL now look like the following:

```

RELATION --> SIMPLE_EXPRESSION SIMPLE_EXPRESSION_TAIL

SIMPLE_EXPRESSION_TAIL --> RELATIONAL_OPERATOR SIMPLE_EXPRESSION
                        --> in RANGES
                        --> not in RANGES
                        --> in TYPE_MARK
                        --> not in TYPE_MARK

```

Finally, in attempting to make our grammar LL(1) it was necessary to combine several similar constructs together so that it could be parsed by one function of the parser. For example, the reserved word **package** appears in several instances including a package specification, a package body declaration, a separate package body declaration, a generic instantiation of a package, and the renaming of a package. In each of these examples the reserved word **package** is used, and even with the ability to look ahead one token, it is impossible to tell which form of the package construct is being utilized. We massaged our grammar so that if **package** is encountered the function PACKAGE_DECLARATION is called. The function PACKAGE_DECLARATION first checks for the reserved word **body**, indicating a package body declaration, or a separate package body declaration. PACKAGE_DECLARATION then checks for an identifier, indicating a package specification, a generic instantiation, or a renaming declaration. If **body** is present then the function PACKAGE_BODY is called. If an identifier is present then the function PACKAGE_UNIT is called. This technique of decision making based on reserved word or terminal symbol presence is extended into the functions

PACKAGE_BODY and PACKAGE_UNIT to further decide which form of **package** is being utilized. In essence, we have expanded the production rules to allow each new production the ability to correctly determine, with one token lookahead, what the next production rule will be. This entire process is also used for the different versions of **procedures**, **functions**, and **tasks** which can appear in an Ada program.

III. LEXICAL ANALYZER

A. INTRODUCTION

Ada is an extremely large language, comparable in size to PL1. It was developed on behalf of the Department of Defense for use in embedded systems [Ref. 13: p.xi]. Based on Pascal, Ada is the first practical language to bring together important features such as data abstraction, multitasking, exception handling, encapsulation and generics [Ref. 13: p.xi]. Our design approach utilizes a division of labor and we separate our metric into phases which perform a single, specific function. The first two phases, *lexical analysis* and *parsing*, combine to form a generic *front-end machine*. This front-end machine constructs an intermediate representation of the source program. The information necessary to implement the metric is then collected and analyzed from the intermediate form. We will look, in depth, at the lexical analyzer and identify how it operates and why it is necessary.

B. TOKENS

Lexical Analysis, often called linear analysis or scanning, is when a stream of characters making up the source program is read from left-to-right and grouped into *tokens*, which are sequences of characters having a collective meaning [Ref. 11: p.4]. The character sequence forming a token, with the legal characters as described in [Ref. 12: p.2-1], is called the *lexeme* for the token. This lexeme is what is used to identify the actual operators and operands that serve as the input for our metric. All variables will have a lexeme, such as *sqrt*, *rate*, *answer*, and so on. There are seven token classes in the Ada language. They are *identifiers*, *separators*, *numeric literals*, *delimiters*, *comments*, *character literals*, and *string literals*. The *lexical analyzer* takes the source program one character at a time, and builds the token lexeme as it determines the token class. Each token is generated by a *finite state automaton*. A finite state automaton, often called a finite state machine, is a mathematical model for a device that is capable of recognizing strings of characters defined by a certain class of grammars, called regular grammars. Our scanner, or lexical analyzer, can be in any one of a finite number of internal configurations or *states* [Ref. 14: p.13]. The state of the system summarizes the information concerning past inputs that is needed to determine the behavior of the system on subsequent inputs. The lexical analyzer scans

the symbols of a computer program to locate the strings of characters corresponding to one of the seven token types mentioned earlier. In this process the lexical analyzer needs to remember only a finite amount of information, such as how long a prefix of a reserved word it has seen since startup [Ref. 14: p.14].

We will now address these tokens individually and discuss not only their purpose and content but also the finite state machines we programmed to handle their recognition.

1. Identifiers

Figure 3.1 Finite State Machine for Identifiers.

Identifiers are used as names and also as reserved words [Ref. 12: p.2-4]. An identifier must start with a letter and it can then be any combination of letters, digits or the underscore character (_). There cannot be two underscore characters side by side in the identifier and there is no maximum length specified for any identifier. Identifiers differing only in the use of corresponding upper and lower case letters are considered as the same [Ref. 12: p.2-4]. The finite state machine we programmed to identify and store token *identifiers* is seen in Figure 3.1.

2. String Literal

A string literal is formed by a sequence of zero or more graphic characters enclosed between two quotation characters (") used as string brackets [Ref. 12: p.2-6]. A string literal has a value that is a sequence of character values corresponding to the graphic characters of the string literal apart from the quotation character itself

Figure 3.2 Finite State Machine for String Literals.

[Ref. 12: p.2-6]. If a quotation character value is to be represented in the sequence of character values, then a pair of adjacent quotation characters must be written at the corresponding place within the string literal. The length of a string literal is the number of character values in the sequence represented, except for doubled quotation characters which are counted as a single character [Ref. 12: p.2-6]. A string literal must fit on one line since it is a lexical element but longer sequences of graphic characters can be obtained by catenation of string literals [Ref. 12: p.2-7]. Except for the instance of doubled quotation characters, the finite state machine we programmed to identify and store token *string literals* can be seen in Figure 3.2.

3. Character Literals

Figure 3.3 Finite State Machine for Character Literals.

A character literal is formed by enclosing one of the 95 graphic characters (including the space), which are described in [Ref. 12: p.2-1], between two apostrophe characters ('). A character literal has a value that belongs to a character type. The finite state machine we created to identify and store token *character literals* can be seen in Figure 3.3.

4. Comments

Figure 3.4 Finite State Machine for Comments.

A comment starts with two adjacent hyphens and extends up to the end of the line. A comment can appear on any line of a program [Ref. 12: p.2-7]. The presence or absence of comments has no influence on whether a program is legal or illegal. Furthermore, comments do not influence the effect of a program. The sole purpose of comments is to provide clarity and explanation to the human reader. The horizontal tabulation can be used in comments, after the double hyphen, and is equivalent to one or more spaces [Ref. 12: p.2-7]. The finite state machine we programmed to identify and store token *comments* can be seen in Figure 3.4.

5. Separators

In certain cases an explicit separator is required to separate adjacent lexical elements (namely, without separation, interpretation as a single lexical element is possible) [Ref. 12: p.2-3]. A separator is any of a space character, a format effector (such as horizontal tabulation, vertical tabulation, carriage return, line feed, and form feed), or the end of a line [Ref. 12: p.2-3]. A space character is a separator except within a comment, a string literal, or a space character literal. The horizontal

Figure 3.5 Finite StateMachine for Separators.

tabulation is not a separator within a comment. One or more separators are allowed between any two adjacent lexical elements (tokens), and at least one separator is required between an identifier or a numeric literal and an adjacent identifier or numeric literal. The finite state machine we programmed to identify and store token *separators* is seen in Figure 3.5.

6. Delimiters

Figure 3.6 Finite State Machine for Delimiters.

A simple delimiter is either one of the following special characters (in the basic character set):

& ' () * + , . / ; < = > | :

A compound delimiter is one of the following, each composed of two adjacent special characters

= > .. ** := = > = < = > > < < < >

Any other combination of adjacent special characters is not a legal compound delimiter. The finite state machine we programmed for identifying and storing token *delimiters* is seen in Figure 3.6.

7. Numeric Literal

The numeric literal is by far the most complex and varied type of token. It encompasses real numbers, integer numbers, and based numbers which are numeric literals expressed in an explicitly specified base between 2 and 16 [Ref. 12: 2-5], p. A real number is a number with a decimal point, an integer is a number without a point and a based literal is, again, a number whose base is explicitly stated. An underline character () inserted between adjacent digits of a numeric literal does not affect the value of this numeric literal. The only letters allowed as extended digits are the letters A through F, which stand for the digits ten through fifteen in hexadecimal. A letter in a based number can be written either in lower case or in upper case, with the same meaning [Ref. 12: p.2-5]. Leading zeros are allowed. No space is allowed in a numeric literal, not even between constituents of the exponent, since a space is a separator. A zero exponent is allowed for an integer literal. The finite state machine we programmed to identify and store token *numeric literals* can be seen in Figure 3.7.

C. TOKEN USE

As was seen in Chapter II, a grammar is made up of terminals, non-terminals, a start symbol, and productions. The terminals are the basic symbols from which strings are formed. These strings are the combinations of the most basic symbols, *tokens*, which form meaningful expressions to a particular language. To be able to analyze these strings and determine whether or not a given string is a legal statement in any given language we must first identify each token as it is entered by the program. Identification of the tokens permits the computer to compact the incoming data thus allowing the saving of space. For example, if someone placed ten blanks in an input program where only one was needed, lexical analysis would see the separator and flush the other unused blanks, thus saving space. Certain tokens will be augmented by a *lexical value*. For example, when an identifier like *rate* is found, the lexical analyzer not only generates a token, say *id*, but also enters the lexeme *rate* into the symbol

Figure 3.7 Finite State Machine for Numeric Literals.

table, if it is not already there [Ref. 11: p.12]. The lexical value associated with this occurrence of *id* points to the symbol-table entry for *id*. The construction of these tokens is done by reading one character at a time and building the lexeme of the token by appending the appropriate characters together. This translation from the input program to a simple stream of tokens is the sole job of the lexical analyzer. In the next chapter we will look at the system parser and its functions.

IV. PARSER

A. INTRODUCTION

The parser, which is the second component of our front-end machine, is the mainstay of our metric. Parsing is also called hierarchical analysis or syntax analysis. It involves grouping the tokens, created by the lexical analyzer, of the source program into grammatical phrases that are used to synthesize output [Ref. 11: p.6]. A parser can be constructed for any context-free grammar. The important factor in parsing is speed. Given a programming language, we can generally construct a grammar that can be parsed quickly. Most programming language parsers make a single left-to-right scan over the input, looking ahead one token at a time [Ref. 11: p.41]. In discussing this parsing problem, it is helpful to think of a parse tree being constructed, even though our *front-end machine* does not actually construct a tree. A parse tree describes the syntactic structure of the input. It pictorially shows how the start symbol of a grammar derives a string in the language [Ref. 11: p.29]. Formally, given a context-free grammar, a parse tree is a tree with the following properties:

1. The root is labeled by the start symbol.
2. Each leaf is labeled by a token or empty string.
3. Each interior node is labeled by a nonterminal.

The leaves of a parse tree, read from left to right, form the *yield* of a tree, which is the string generated or derived from the nonterminal at the root of the parse tree [Ref. 11: p.29]. The term, *context-free grammar*, which is mentioned earlier, defines a finite set of variables (also called nonterminals or syntactic categories), each of which represents a language [Ref. 14: p.77]. A *context-free grammar* is denoted $G = (V, T, P, S)$, where V and T are finite sets of variables and terminals respectively [Ref. 14: p.79]. P is a finite set of productions; each production ($A \Rightarrow W$) is of the form A produces W where A is a variable and W is a string of symbols from any combination of $(V \cup T)$. Finally, S is the start symbol. It must be noted though that although our front-end machine is capable of constructing a parse tree (otherwise the translation would not be guaranteed correct) the actual tree is not necessary for our metric purposes and is therefore not built.

Most parsing methods fall into one of two classes, *top-down* and *bottom-up* methods [Ref. 11: p.41]. These terms refer to the order in which nodes in the parse tree, if the tree actually existed, were constructed. In the top-down method, construction starts at the root and proceeds towards the leaves going deeper and deeper until eventually reaching the bottom. In the bottom-up method it is just the opposite. Construction starts at the bottom and proceeds towards the root. The popularity of top-down parsers is due to the fact that efficient parsers can be constructed more easily by hand using top-down methods [Ref. 11: p.41]. Bottom-up parsing, however, can handle a larger class of grammars and translation schemes, so software tools for generating parsers directly from grammars have tended to use bottom-up methods [Ref. 11: p.41]. Because of its efficiency and ease of use, we have chosen to use the top-down method of parsing for the front-end machine of our metric. Furthermore, we chose a particular type of top-down parsing called recursive-descent. This technique, a classical method often used in industry, is very powerful. We describe its operation in the following section.

B. TOP-DOWN RECURSIVE DESCENT PARSING

Recursive-descent parsing is a top-down method of syntax analysis in which we execute a set of recursive procedures to process the input [Ref. 11: p.44]. A function is associated with each nonterminal of a grammar. We now consider a special form of *recursive-descent* parsing, called predictive parsing, in which the token symbol unambiguously determines the function selected for each nonterminal [Ref. 11: p.44]. The sequence of functions called in processing the input implicitly defines a parse tree for the input.

Our procedure GET_CURRENT_TOKEN_RECORD builds an array of fifty tokens and, starting at the initial position controls a pointer which identifies the current token being parsed and another pointer which identifies the next or *lookahead* token to be parsed. The function BYPASS is the central control and workhorse for our parser. It compares the current token with predefined terminals. If there is a token-to-terminal match, BYPASS consumes the token by adjusting the index pointers. All of the terminal symbols in the Ada language are defined and any nonterminal is, as was stated earlier, a function call that returns a boolean value of true or false.

Parsing begins with a call for the starting nonterminal, which is COMPILATION in the Ada grammar. Parsing progresses as each function calls other functions,

descending into the parse structure until a call to BYPASS is performed and the appropriate boolean value is returned. This process of ascending and descending the parse structure continues until all the tokens created from the input file have been consumed or an error occurs.

We made an attempt to design the parser to be as robust as possible. However, due to the complexity of the language we were often forced to rely on the fact that the input file had been correctly compiled before being fed into our parser. The fact that the input file was precompiled allowed us to drop the *italicized* element of the nonterminals in the grammar. Some examples of this modification are:

1. A parser for a compiler would normally have to remember the type associated with NAME each time it was encountered. In our case we simply dropped the type requirement and parsed all of them with the function NAME. For example, all of the following are reduced to just NAME: TYPE_NAME, VARIABLE_NAME, PROCEDURE_NAME, FUNCTION_NAME, ENTRY_NAME, and this list is far from complete.
2. Another example occurred when we dropped the italicized element of the nonterminal EXPRESSION. Since the type had been checked by a full compiler, for our parser the following three nonterminals became simply EXPRESSION: UNIVERSAL_STATIC_EXPRESSION, QUALIFIED_EXPRESSION, and BOOLEAN_EXPRESSION. The following two nonterminals became SIMPLE_EXPRESSION for the same reasons: STATIC_SIMPLE_EXPRESSION, and DELAY_SIMPLE_EXPRESSION.
3. Our third example is that by dropping the italicized element of DISCRETE SUBTYPE INDICATION and COMPONENT SUBTYPE INDICATION, they can both be correctly parsed by SUBTYPE_INDICATION.

The changes highlighted above, and others that are not shown, were done to reduce the size and complexity of the parser. Having to retain all the type information would have required a much more extensive parsing element. This reduction allows our parser to be more efficient in its operation. We did not intend for our front-end machine to be a full compiler. We only needed to parse an input file in enough detail to be able to collect the meaningful and relevant metric data.

V. ADAMEASURE

A. INTRODUCTION

As was seen in the first chapter of our thesis there is a variety of different metric theories. By request of the Missile Software Branch, Naval Weapons Center, China Lake, we implemented the Halstead Software Science Metric. In the effort to provide as much information about the input program as possible, we also provide information on comments and nesting. We felt it was important to avoid trying to generate a single number, say between one and ten, which would be an attempt to quantify the given metric information into a single numeric statement. Instead we generate a few important numbers, then we apply some reasoning to what we believe these numbers mean in relation to program complexity and overall software quality. We stress what the program says about the software is merely suggestive.

B. DATA COLLECTION

In explaining the how and why of our data gathering, we will deal with each of the three types of information analysis separately.

1. Halstead Data

As stated in chapter one, we only implemented the program length metric from Halstead's software science theory. We gathered the *operator* data through our workhorse function BYPASS which counted every token-to-operator terminal match. To acquire the *operand* data we generated a symbol table of all identifiers, be they variables, procedures, functions, tasks, blocks, or numeric constants. Once this was completed we now had the four Halstead parameters n_1 , n_2 , N_1 , and N_2 . Having calculated the *theoretical length* and *actual length* we divided both of these numbers by *total lines input* to allow comparisons of results from programs of different size.

If the actual length is greater than the theoretical length Halstead hypothesized that the difference is caused by one or more of the following six classes of impurities.

- Cancelling : The occurrence of an inverse cancels the effect of a previous operator; no other use of the variable changed by the operator is made before the cancellation.
- Ambiguous operands : The same operand is used to represent two or more variables in an algorithm.

- Synonymous operands : Two or more operand names represent the same variable.
- Common subexpressions : The same subexpression occurs more than once.
- Unnecessary replacements : A subexpression is assigned to a temporary variable which is used only once.
- Unfactored expressions : There are repetitions of operators and operands among unfactored terms in an expression.

If the theoretical length is greater than the actual length then the following conditions could exist:

- Operands : There may be some variables which were declared but never referenced in the program.
- Globals : A large number of the variables referenced were declared in the packages instantiated by the WITH statement.

2. Comment Data

As the input file is parsed, a count is kept of the comment lines. Upon completion of parsing the number of comment lines is divided by the total lines input, then multiplied by one-hundred to yield the overall comment percentage. On the basis of this percentage we make recommendations, that might prove helpful to the software engineer. Briefly, we consider a comment percentage between zero and fifteen percent as low and we state that unless the program utilizes Ada's extensive variable identification ability then there may be too few comments for adequate reader comprehension. We consider a comment percentage between fifteen and fifty as a reasonable number and state that this could give the reader a good understanding of the program. A comment percentage between fifty and eighty-five percent is considered fairly high and we state that the program has good understandability but runs a small risk of obscuring the code. Lastly, a comment percentage between eighty-five and one-hundred percent is an extremely high percentage and we say that the program has a higher possibility of obscuring the code in the high number of comments.

3. Nesting Data

Determining a program's complexity is not an easy thing but it is generally accepted that as the nesting level increases so goes the complexity level. We have implemented a nesting level summary which counts how frequently a given nesting level was reached, maintains a record for each level, and keeps track of the maximum level used and where it was first encountered.

VI. CONCLUSIONS

A. METRICS

The Department of Defense's interest in metrics provides a powerful motivation for the continued research into possible metric tools. The software crisis is severe enough to warrant tools, aids, just any bit of information that will improve the software engineering process. Computer Science is such an infant in the world of academia and metrics is such a very small part of this child that we are aware of the difficulty in finding breakthroughs. The computer scientists may have tried to "catch-up" with the other sciences much too rapidly, consequently they may have missed laying some of the necessary foundations.

Our initial effort is a good start, a baseline from which future efforts can build upon. AdaMeasure is a helpful tool for providing the software engineer with the information that is presently gathered by hand. We do not feel software metrics should simply attempt putting a number onto a program in the effort to quantify its quality. Text describing what the metric has seen and how it relates to the programmer and the program is what is really needed for the output. It is this bridging from the concrete world of the metric to the abstruse, metaphysical environment of the actual software that presents the real challenge. As we collect and analyze the data, we bridge this gap by providing recommendations to the user on how we see the interrelationship of these two entities. These recommendations are based on currently accepted software practices.

B. IMPLEMENTATION

In our effort to make the Ada grammar more LL(1)-like we were forced to perform extensive massaging. This massaging allowed us to use the top-down, recursive-descent parsing technique. This classical, time tested method proved to be easily implemented and debugged. The extensive massaging made it necessary for us to frequently check and reaffirm that the language generated by our newly transformed grammar was exactly the same as the initial language. This point cannot be overstated. The languages must be identical. Because of the complexity involved in massaging and checking the grammar, we feel we have some insight into how languages are created, how they build upon themselves, and where languages are going in the future.

When we originally accepted the proposal for creating a metric, we were not aware of how complex and time consuming the implementation of the front-end machine would be. This complexity, coupled with the fact that Ada is a brand new language and relatively unknown other than by name, made it a struggle until we had significantly progressed along the learning curve. We found the Ada compiler, which is currently a state-of-practice compiler, to be extremely slow in comparison to the compilers we were familiar with such as Pascal or Fortran. The Naval Postgraduate School has no Ada compiler so we were forced to work over Arpanet or Telnet for the actual programming. This presented problems and delays on a regular basis. The expiration of access card numbers, the malfunctioning of the bridge box, the networks going down, the slow baud rate between stations, and machine downtime at NWC China Lake, both scheduled and nonscheduled, made information transfer a real hurdle in the overall effort.

C. THE FUTURE

Having designed a generic metric tool, we hope the program will be expanded and improved. There is already a plan in progress to have Sallie Henry and Dennis Kafura's Complexity Flow Metric implemented. There is a real need for user interface improvements. Because of the limited hardware options available to us, we have programmed our interface to deal with the VT-100 terminal. To make the system more robust and transportable, an interface scheme that would be functional from a variety of different terminals would be a useful endeavor.

This metric was undertaken at the request of NWC China Lake and all of our efforts have been guided by their input to us. Pragmas, which are used to convey information to the compiler, are currently being used in run-time systems only at China Lake and although they are in the Ada grammar we have not implemented them in our metric. It would greatly increase the value of the program if the pragma portion of the grammar were implemented. The Software Missile Branch of NWC China Lake has provided all the Ada programs at their disposal to help us test our metric for proper parsing. We have successfully tested our metric on all these files and we have successfully tested our own code by feeding our metric into itself. Although our tests have been successful we have not tested all of our code. There is a particular need for programs that will test our metric in the area of tasking and all the code that is associated with it. This testing effort should be carried out as soon as possible.

Metrics are important. We hope that our initial work will be expanded and put to real use as a aid to the software engineer. Although Ada is new and relatively unexplored as a language, we feel it will begin to build and become more popular. We hope our metric adds to this building process.

APPENDIX A

MODIFIED ADA GRAMMAR

Our translation key has terminal symbols as lowercase letters, nonterminal symbols as uppercase letters, and bold-faced symbols to indicate the meta-symbols of our grammar.

APPENDIX B

'ADAMEASURE' USERS GUIDE

1. Once you have logged on a VT100 terminal, type RUN DEMON to begin execution of 'AdaMeasure'. The initial screen gives the general information about the program.

```
*****
*
*                               *
*      WELCOME TO 'AdaMEASURE'  *
*                               *
*      AUTHORED BY: LCDR JEFFREY L. NIEDER, USN *
*                  LT  KARL S. FAIRBANKS , USN  *
*                               *
*      NAVAL POSTGRADUATE SCHOOL *
*      DEPARTMENT OF COMPUTER SCIENCE *
*      MONTEREY, CALIFORNIA      *
*                               *
*      31 OCTOBER 1986          *
*                               *
*      VERSION 1.0              *
*                               *
* This program provides an automated software metric tool which *
* uses quantitative measures in an effort to supply the user with *
* helpful information about the static structure of a given input *
* program. This program is public domain information.             *
*                               *
*****
--- Enter any letter to continue ---
```

2. Enter any letter to continue. This is required because Ada filters out carriage returns so just hitting ENTER will not cause execution to continue. The next screen shown is the MAIN SELECTION MENU. From here the user enters the digits 1, 2 or 3 to either parse a file, view previously gathered data, or quit to the operating system, respectively.

```
*****
*
*                               *
*      MAIN SELECTION MENU      *
*                               *
*      HERE ARE THE ACTION CHOICES AVAILABLE TO YOU *
*                               *
*      Simply enter the number of your choice *
*                               *
*      1 - PARSE AN INPUT FILE  *
*                               *
*      2 - VIEW PREVIOUSLY GATHERED DATA *
*                               *
*      3 - EXIT TO OPERATING SYSTEM *
*                               *
*****
Choice =
```

3. If the user selects number one then he will be prompted for the file name of the file he wishes to have parsed. While parsing of the file is in progress, the user will see a message on the screen indicating at what line number, in the input file, the parser has

reached. When parsing of the input file commences, 'AdaMeasure' creates four new files. The four files have the same name as the user's input file with the following extensions: fn.DATA, fn.HALS, fn.RAND, fn.MISC. The meaning of each of these new files will be explained later in this user's guide.

4. Upon conclusion of parsing the input file, or if the user selects number two from the MAIN SELECTION MENU, the program displays the METRIC SELECTION PROGRAM. From this menu, the user can select any of the listed metrics, exit to the MAIN SELECTION MENU, or exit to the operating system.

```
*****
*
*                               METRIC SELECTION MENU                               *
*
*   HERE ARE THE INFORMATION CHOICES AVAILABLE TO YOU                             *
*
*   Simply enter the number of your choice                                         *
*
*   1 - 'HALSTEAD' METRIC INFORMATION                                              *
*
*   2 - COMMENT AND NESTING METRIC INFORMATION                                    *
*
*   3 - 'HENRY and KAFURA' METRIC INFORMATION                                    *
*
*   4 - EXIT TO MAIN MENU                                                         *
*
*   5 - EXIT TO OPERATING SYSTEM                                                  *
*
*****
Choice =
```

5. If number one is selected, the Halstead Metric choice, the next menu displayed is the HALSTEAD SELECTION MENU. From this menu, the calculations and conclusions of the Halstead Metric can be selected. There also exists the options of exiting to the METRIC SELECTION MENU, or exiting to the operating system.

```
*****
*
*                               HALSTEAD SELECTION MENU                               *
*
*   HERE ARE THE HALSTEAD METRIC OPTIONS AVAILABLE TO YOU                         *
*
*   Simply enter the number of your choice                                         *
*
*   1 - HALSTEAD OPERATORS                                                        *
*
*   2 - HALSTEAD OPERANDS                                                         *
*
*   3 - HALSTEAD METRIC CONCLUSIONS                                             *
*
*   4 - EXIT TO METRIC SELECTION MENU                                             *
*
*   5 - EXIT TO OPERATING SYSTEM                                                  *
*
*****
Choice =
```

6. From the HALSTEAD SELECTION MENU, if number one is selected, the Halstead operator data is displayed. The operator data is stored in the fn.DATA file. The Halstead operator data includes the total number of different operators used, the total number of occurrences of those operators, and the number of occurrences of each individual operator.

7. If number two from the HALSTEAD SELECTION MENU is chosen, the HALSTEAD OPERAND SELECTION MENU is displayed. From this menu the different classes of operands and their data can be selected for viewing. Also available for selection are exiting to the HALSTEAD SELECTION MENU, and exiting to the operating system.

```
*****
*
*              HALSTEAD OPERAND SELECTION MENU              *
*
*              HERE IS THE OPERAND DATA AVAILABLE           *
*
*      Simply enter the number of your choice                *
*
*      1 - PROCEDURE, FUNCTION, PACKAGE INFORMATION          *
*
*      2 - VARIABLES AND CONSTANTS INFORMATION               *
*
*      3 - TASKS AND BLOCKS INFORMATION                      *
*
*      4 - EXIT TO HALSTEAD SELECTION MENU                   *
*
*      5 - EXIT TO OPERATING SYSTEM                          *
*
*****
Choice =
```

8. From the HALSTEAD OPERAND SELECTION MENU, selection of any of the operand classes will show each identifier and number of occurrences of for that particular class. The data for all operand classes is stored in the fn.RAND file.

9. Back to the HALSTEAD SELECTION MENU. If the selection is number three, the Halstead Metric conclusions are displayed. The conclusions include the input file's calculated theoretical length, its actual length, the difference between the two lengths, and some comments about that difference. The Halstead Metric conclusion data is stored in the fn.HALS file.

10. Back to the METRIC SELECTION MENU. If the selection number is two, the comment and nesting metric information is displayed on the screen. The comment metric information includes the total number of lines in the input file, the total number

of comment lines, a percentage of lines of comments to lines of code, and some observations about that percentage. The nesting metric information contains the type and total occurrences of nesting constructs used in the input file, the deepest level of nesting parsed, and how many times each nesting level, up to the deepest, was encountered. The comment and nesting metric information is stored in the fn.MISC file.

11. The final choice in the METRIC SELECTION MENU is the Henry and Kafura Complexity Flow Metric. At present, this metric is not implemented. Ongoing development of 'AdaMeasure' includes plans to implement this metric as well as other metrics and Ada tools.

APPENDIX C

'ADAMEASURE' PROGRAM LISTING - PART 1

```

--*****--
--
-- TITLE:          AN ADA SOFTWARE METRIC
--
-- MODULE NAME:     PACKAGE BYPASS_FUNCTION

--
--  TITLE:          AN ADA SOFTWARE METRIC
--
--  MODULE NAME:    PACKAGE PARSE2
--  DATE CREATED:   18 JUL 86
--  LAST MODIFIED:  04 DEC 86
--
--  AUTHORS:        LCDR JEFFREY L. NIEDER
--                  LT KARL S. FAIRBANKS, JR.
--
--  DESCRIPTION:    This package contains thirty-three functions
--                  that are the middle level productions for our top-down,
--                  recursive descent parser. Each function is preceded
--                  by the grammar productions they are implementing.

-- TITLE:          AN ADA SOFTWARE METRIC
--
-- MODULE NAME:    PACKAGE_PARSER_3
-- DATE CREATED:   22 JUL 86
-- LAST MODIFIED:  03 DEC 86
--
-- AUTHORS:        LCDR JEFFREY L. NIEDER
--                  LT KARL S. FAIRBANKS, JR.
--
-- DESCRIPTION:    This package contains thirty-five functions
--                  that make up the baseline productions for our top-down,
--                  recursive descent parser. Each function is preceded
--                  by the grammar productions they are implementing.

-- AUTHORS:        LCDR JEFFREY L. NIEDER
--                  LT KARL S. FAIRBANKS, JR.
--
-- DESCRIPTION:    This package contains seven functions that
--                  are the lowest level productions for our top-down,
--                  recursive descent parser. Each function is preceded
--                  by the grammar productions they are implementing.

--
--  TITLE:          AN ADA SOFTWARE METRIC
--
--  MODULE NAME:    PACKAGE SCANNER
--  DATE CREATED:   06 JUN 86
--  LAST MODIFIED:  04 NOV 86
--
--  AUTHORS:        LCDR JEFFREY L. NIEDER
--                  LT KARL S. FAIRBANKS, JR.
--
--  DESCRIPTION:    This package reads each character from the
--                  input buffer, determines its token class and calls
--                  the appropriate procedure.
