PREFACE

This product specification covers the work performed under Air Force Contract F33615-80-C-5155 (ICAM Project 6201). This contract is sponsored by the Materials Laboratory, Air Force Systems Command, Wright-Patterson Air Force Base, Ohio. It was administered under the technical direction of Mr. Gerald C. Shumaker, ICAM Program Manager, Manufacturing Technology Division, through Project Manager, Mr. David Judson. The Prime Contractor was Production Resources Consulting of the General Electric Company, Schenectady, New York, under the direction of Mr. Alan Rubenstein. The General Electric Project Manager was Mr. Myron Hurlbut of Industrial Automation Systems Department, Albany, New York.

Certain work aimed at improving Test Bed Technology has been performed by other contracts with Project 6201 performing integrating functions. This work consisted of enhancements to Test Bed software and establishment and operation of Test Bed hardware and communications for developers and other users. Documentation relating to the Test Bed from all of these contractors and projects have been integrated under Project 6201 for publication and treatment as an integrated set of documents. The particular contributors to each document are noted on the Report Documentation Page (DD1473). A listing and description of the entire project documentation system and how they are related is contained in document FTR620100001, Project Overview.

The subcontractors and their contributing activities were as follows:

SECTION 1

SCOPE

1.1 Identification

This specification establishes the 'as built' design of the Message Processing Unit component of the Network Transaction Manager Subsystem.

1.2 Functional Summary

The Network Transaction Manager (NTM) Subsystem provides the control and support services to application processes that are grouped together logically in clusters called Application Process Cluster (APCs). These application processes communicate with one another by sending messages via the NTM. The NTM delivers these messages to the destination application processes while also providing other services for the APs such as message pairing, AP initiation, and message queuing.

2.2 Terms And Abbreviations

1. Interhost Communication Primitives (IHC's) - A set of routines used by the NTM to interface to the operating system or to other operating systems which have an NTM running. They are always system dependent.
2. Interprocess Communication Primitives (IPC's) - A set of routines used to communicate between two processes on the same computer. They are always system dependent.

SECTION 3

REQUIREMENTS

3.1 Structural Descriptions

The Message Processing Unit has three stages of operation: Start-up, Input Processing, and Shutdown. The Monitor Application Process (Monitor AP) initiates the first instance of and MPU, the Monitor MPU. All other MPUs are then initiated by the Monitor MPU.

3.2 Functional Flow Description

The Start-up stage of an MPU begins with getting the MPU's process name from the operating system and creating both high- and low-priority mailboxes. The MPU then sends a message to the Monitor AP requesting the status of the tables on the cluster and waits for a response from the Monitor AP. If the response does not arrive within a given amount of time, the MPU will send an "AP CLUSTER TERMINATING" message to the Monitor AP and will then proceed to terminate. If the message does arrive saying that the tables are correct, then the MPU will populate its tables with the information saved in local files via table initialization procedures. The MPU then sends an "AP CLUSTER ALIVE" message to the Monitor AP and waits for final start up instructions.

As a final instruction, if an error occurs during the IISS start-up, the Monitor AP will instruct each Message Processing Unit to terminate. Also, if the final instruction message does not arrive within a certain period of time, the MPU will begin the AP Cluster termination process on its own. However, if the IISS start-up is successful, then the Monitor AP will send a "HOST ACTIVE" message to signal the MPU that Start-Up is complete. The MPU is now ready for its second phase of operation: Input Processing.

During the Input Processing stage, the MPU remains available to the users who are logged onto the IISS and to other application processes. User application processes can communicate with one another and initiate other application processes by sending messages through the MPU. The MPU processes these messages in two phases: Manage Message, and Process Message.

The Manage Message Phases authorizes the message, verifies the message category, assigns a serial number, and completes the header of messages from on the cluster. If the message is from another cluster, Manage Message verifies that the message arrives at the correct destination. If a message error occurs, the NPU will send an error message to the source AP. If a system error occurs, the NPU will send an error message to the Monitor AP. All messages are logged in Manage Message. This is also where the type of processing to be done on the message is determined. Messages destined to go off-host are sent to the Communication cluster's NPU, messages destined to stay on-host but off-cluster are delivered to the off-cluster NPU, and messages destined for on-cluster are processed by phase two of Input Processing. Manage Process

Manage Process handles each message destined for the AP Cluster according to its message category and type. Some messages cause the initiation of other application processes in the IISS, others are simply delivered to the destination AP. All message processing done by the NPU requires table access. Information about individual AP instances and types of APs are kept in several tables.

For example, every time an initiation message arrives at the Manage Process phase, the NPU must check the AP Characteristics Table to be sure that the AP can be started by that type of initiation message. If the AP can be initiated by that type of message, the NPU must then check the AP Information Table to be sure that the maximum number of instances allowed has not yet been reached. Finally, if the AP is initiated successfully, an AP Status Table entry is created for that AP. The AP Status Table has an entry for every instance of an application process that is communicating via the IISS. There are many different types of application processes running under the IISS and all are at different stages of processing at any given moment. All of this information is stored in tables for the NPU's use in order that all kinds of messages may be processed.

Also during the Input Processing phase of the NPU, a timer is set to a fixed length of time. When the timer goes off, a checking routine is invoked. The checking routine looks at certain tables and processes each entry in the table according to its status. For example, the Message Pair table has an entry for each message that requires a response. If the time-out time on the entry has passed (compared to the system's time) then the NPU deletes the entry and send a "TIME-OUT ERROR" message to the

Monitor AP. The checking routine also processes messages that have been stored up in queues. For example, if the NPU tries to deliver a message to an AP whose mailbox is full, the message will be queued so that it can be sent again later by the checking routine. After completion of the checking routine, the timer is reset so that it may be invoked again after a fixed period of time.

Besides handling application process messages, the NPU has a high-priority mailbox from which it reads system command messages from the IISS operator via the Monitor AP. For instance, the operator can request a list of all active APs on the NPUs cluster or request the shutdown of a particular application process. The system command message that requires the NPU to go into its final stage of operation, SHUTDOWN, is a "SHUTDOWN AP CLUSTER" message from the operator via the Monitor AP.

The Shutdown stage of the Message Processing Unit operates basically like the Input Processing stage: messages are still processed by the NPU but in a different way. When the NPU received the "SHUTDOWN APC" message, it looks at each application process in the AP Status Table and, according to each AP's characteristic, aborts the AP or informs it that it must shut itself down. The NPU then checks its mailboxes for a message from each of the APs that were told to shutdown. Only AP status messages and system commands from the Monitor AP (such as "CANCEL SHUTDOWN") are processed normally during the shutdown phase. All other types of messages are logged and ignored by the NPU. The NPU systematically checks to see if all the application processes on the cluster are dead. If no more messages are in the mailboxes to be processed and all the APs are no longer running, the NPU invokes its final shutdown processing. The AP Cluster initialization data is saved in a local file where it will be used during the next IISS or cluster startup. The NPU's input mailboxes are deleted and an "APC TERMINATING" message is sent to the Monitor AP. The Message Processing Unit then ends execution.

3.3 Interfaces

The Network Transaction Manager maintains communications with any other process through mailboxes. The mailboxes are managed by the Interprocess Communication Primitives (IPC's).

Communications with the remote computer is accomplished through the Communication sub-system process which will be

running when there are other hosts to communicate with.

3.4 Program Interrupts

As mentioned previously, NTM is interrupt driven with interrupts coming either from the IPC's on behalf of any other process which may be another MPU or any other AP. Waiting for these interrupts is performed by one of the IPC wait primitives. If a response must be received within a particular time interval, the IPC's associated with timing are used along with one of the wait's.

3.5 Timing and Sequence Description

The NTM does not depend on any particular timing sequences.

3.6 Special Control Features

The Network Transaction Manager Subsystem does not include any special control features as defined in the ICAM Documentation Standards manual.

3.7 Storage Allocation

3.7.1 Data Base Definition

The NTM uses files and tables to store static configuration and dynamic operating information. These are described in the Development Specification (DS 620142000) and in the include files referenced in Section 3.10.9 of this document.

3.7.1.1 File Description

NTM uses many files for table handling. This involves reading the initial values of the tables as well as using files for table overflow handling. Files are also used to buffer messages and to log normal and error messages.

3.7.1.2 Table Description

The NTM Tables provide both static and dynamic data to the NTM MPU. The static data consists of configuration data, such as the location of an AP within the IISS, characteristics of a given AP, etc. The dynamic data consists of the run-time status of the NTM components, the IISS host machines, and the user's APs. There are currently fifteen NTM Tables. Their content is described in detail in the Development Specification.

3.7.1.3 Item and Constant Description

Symbols are defined in the Development Specification and in the include files.

3.7.2 CPC Relationship

3.8 Object Code Creation

The generic portion of NTM is written in COBOL and 'C'. This has been successfully compiled on a VAX 11/780 under VMS (Rel 2.0), an IBM 3084 under MVS (Rel 1.8), and a Honeywell Level 6 under Mod 400 (Rel 1.2).

The machine specific code of the NTM is written in COBOL. The different methods of handling files must be dealt with separately on each machine. This has been successfully compiled on a VAX 11/780 under VMS, an IBM 3084 under MVS, and a Honeywell Level 6 under Mod 400 at appropriate release levels as noted above.

The minimum computer hardware and software required to create and run NTM in the IISS environment is documented in the Installation Guide for IISS on the VAX and in the Installation Guide for IISS on the IBM.

3.9 Adaption Data

In order to tailor NTM to either the VAX or the IBM, there are a few system dependent files required. For example, the table file handlers would have to be tailored to the particular machine you are on.

The command procedures to the create NTM executables are specific to each computer and can be found under Software Configuration Management.

3.10 Detail Design Description

The upcoming program details were derived from all modules that were selected when the following Documentation Group(s) was chosen:

NTMMPU

3.10.1 Main Program List

The following is a list of all "Main Programs" which are modules that are not called by any other module being documented here. These modules are either program entry points or, if they are hooked into another set of programs via subroutine calls, they are the points the external programs can call and therefore enter through. To differentiate between the two types of entry points, look at the individual Module Documentation (section 3.10.8) and look at Module Type for each of the Main Program modules listed. Note whether the routine is a Program, Subroutine, or Function. If it is a Program, it is truly a main program entry point. If not, then it is merely called by other programs not being documented here.

The following is a list of all routines or functions not documented here that are called by modules that are documented here. The first caller, in alphabetical order, is listed as well. The specification in which any module is documented may be found in the Module Documentation Index (Document Number CM 620100001). See section 3.10.6 for a list of the modules that call each of these external routines.

3.10.4 Include File List

The following is a list of all include files called in by modules being documented here. Each include file has a unique name regardless of the language being used. The purpose of each include file is listed as well. A more complete description of each include file is given in section 3.10.9. The purpose listed is the one that is in the source code of the include file.

A purpose of "**** PURPOSE NOT FOUND BY STRIPPER ****" indicates that a purpose statement was not written into the include file itself. The most common reason for this is that the include file comes from system libraries that were not developed by the project, such as 'C' libraries that are provided with the 'C' compiler.

See section 3.10.6 for a set of lists which show all the modules which call in each of these include files.

3.10.7 Main Program Parts List

The following lists each Main Program listed in 3.10.1 and all the modules which are called either by that module itself or by any of the documented modules which it calls. It is possible for a non-main module to be listed more than once if it is called by multiple modules. The called modules, in this case known as program parts, are marked as to whether they are documented here. If so, the phrase "well-defined module" appears by the module name, if not it is an "external routine". The Purpose of the Main Program module is listed as well.

3.10.8 Module Documentation

The following documentation describes information which is specific to each individual module being documented in this specification as listed in section 3.10.2. It provides a compact way of getting information that would be otherwise buried within each module's source code.

The specific items in this module documentation have the following meanings:

NAME:	Name of program Module.
PURPOSE:	Purpose of Module as detailed in the source code.
LANGUAGE:	Programming language source code is written in. The choices are: VAX-11 FORTRAN C (I/S-1 Workbench 'C') VAX-11 COBOL
MODULE TYPE:	Whether a Program, Subroutine, or Function.
SOURCE FILE:	Name of Source File from file specification.
SOURCE FILE TYPE:	Source File Extension from file specification.
HOST:	Whether this is a host-dependent routine (VAX or IBM) or blank if host-independent.
SUBSYSTEM:	IISS sub-system this file resides in.
SUBDIRECTORY:	Sub-directory of that subsystem in which this file resides.
DOCUMENTATION GROUP:	Name of documentation group of which this source file is a member.
DESCRIPTION:	A description of the module as obtained

PS 620142200
1 November 1985

from the source code.

ARGUMENTS: The arguments with which this routine is called if it is a Subroutine or a Function.

INCLUDE FILES: A list of all the files that are included into this module as well as their purposes.

ROUTINES CALLED: Subroutines or Functions, either documented or external, called by this module, if any.

CALLED DIRECTLY BY: The documented routines which call this module, if any.

USED IN MAIN PROGRAM(S): The documented Main Programs which contain this module in their parts list according to the list in section 3.10.7.

The Module Documentation is arranged alphabetically according to Module Name.

DESCRIPTION:

- PROCESS AN AP DYING MESSAGE BY UP-
DATING THE AP STATUS TABLE. IF NOT IN THE
IISS SHUTDOWN MODE AND THE AP'S KIDS ARE DEAD
AND THE AP IS NOT IT'S OWN PARENT(SOME UI APS)
THEN SEND A CH:LD STATUS MESSAGE TO THE PARENT.
IF THE AP IS IT'S OWN PARENT THEN CALL 'CLNUP'
TO DELETE THE AP STATUS ENTRY. THE INSTANCE
COUNT IS ALSO DECREMENTED AND THE AP OPERATING
TABLE IS UPDATED. FINALLY, THE WAIT-INIT
QUEUE IS CHECKED FOR AN INIT MESSAGE AWAITING
A FREE INSTANCE SO IT CAN BE PROCESSED. IF IN
SHUTDOWN MODE, 'SEARCH-START-FLG ALDEAD' IS
CALLED TO DETERMINE IF THE DEAD AP WAS THE LAST
TO DIE ON THE APC.

DESCRIPTION:

- IF APC IS NOT IN A SHUTDOWN MODE, THE MPU WILL WAIT ON EVENTS AND HANDLE THE APC INPUT. THREE EVENTS ARE WAITED FOR: TIME TIMEOUT, MSG IN HI-PRIORITY MBX AND LOW-PRIORITY MBX. WHEN A MBX EVENT TAKES PLACE, THE MSG IS READ AND PROCESSED VIA MANAGE MESSAGE AND THEN (IF NO ERROR) THE MSG IS ROUTED AND SENT. IF THE TIMER EVENT TAKES PLACE, A PROCESS IS CALLED TO CHECK THE CERTAIN QUEUES AND TABLES FOR CERTAIN CONDITIONS. IF THE APC IS IN A SHUTDOWN MODE, EVENTS ARE NOT WAITED FOR BUT THE MBXS ARE CHECKED FOR MSGS. THE MSGS ARE READ AND PROCESSED BY A SPECIAL "SHUTDOWN MODE" PROCESS. ONLY AP STATUS MSGS AND SYSTEM COMMANDS WILL GO ON TO BE PROCESSED BY MM AND ROUTE & SEND.

DOCUMENTATION GROUP: NTMMPU

DESCRIPTION:

- IF THE APC IS "COMM" OR THE MSG PRIORITY IS 0, THEN THE MSG IS WRITTEN TO THE AP'S COLD MBX OTHERWISE IT IS WRITTEN TO THE AP'S HOT MB. IF THE MBX IS NOT FOUND THEN THE AP'S MNX CHARS ARE CHECKED TO SEE WHAT MBXS SHOULD EXIST FOR THE AP. IF THE MBX IS SUPPOSED TO EXIST AND DOES NOT, A PROCESSING ERROR IS SENT TO THE OPERATOR VIA MTR AP. IF THE MBX IS NOT SUPPOSED TO EXIST THEN A 'MSG ERROR' MSG IS SENT TO THE SRC AP.

ARGUMENTS:

AP-CHAR-TABLE = RECRD

INCLUDE FILES:

APTBUF	- AP CHAR TABLE RECORD BUFFER.
SDSPDT	- MPU TO AP ERROR MESSAGE FORMAT.
SDMNDT	- MPU TO MONITOR ERROR MESSAGE FORMAT.

3.10.10 Hierarchy Chart

The following hierarchy charts show the relationships between all of the modules mentioned in the above documentation. A module may call a subroutine several times within its code, but the call will only be shown once as a single relationship on this hierarchy chart. All modules shown at the top of the first page are considered Main Programs as described in section 3.10.1 above.

There is an internal paging scheme as marked by the numbers in the upper right corner of each page. An index after the last page of the chart shows where a routine and its calls are first defined. If a routine has no page reference, it either makes no calls or is an external routine. A continuation box on the end of a tree limb shows where that the tree continues on the page number mentioned. A number in a box with a routine name points to the page where the routine is further defined within the hierarchy tree. If there is no number in a box, the routine either makes no calls or is an external routine.

SECTION 4

QUALITY ASSURANCE PROVISIONS

4.1 Introduction and Definitions

"Testing" is a systematic process that may be preplanned and explicitly stated. Test techniques and procedures may be defined in advance and a sequence of test steps may be specified. "Debugging" is the process of isolation and correction of the cause of an error.

"Antibugging" is defined as the philosophy of writing programs in such a way as to make bugs less likely to occur and when they do occur, to make them more noticeable to the programmer and the user. In other words, as much error checking as is practical and possible in each routine should be performed.

4.2 Computer Programming Test and Evaluation

The quality assurance provisions for test consists of the normal testing techniques that are accomplished during the construction process. They consist of design and code walk-throughs, unit testing, and integration testing. These tests are performed by the design team. Structured design, design walk-through and the incorporation of "antibugging" facilitate this testing by exposing and addressing problem areas before they become coded "bugs".
