ABSTRACT

A software metric is a tool that should be used in the development of quality software. The properties that define good software vary but encompass reliability, complexity, efficiency, testability, understandability, and modifiability. The Henry metric measures the complexity of data flow within a module and the complexity of inter-module communication. This thesis is an extension of a previous thesis titled 'AdaMeasure' that calculated the Halstead metric. The present design and implementation is a tool that computes the Halstead and Henry metrics for Ada programs.

I. INTRODUCTION AND BACKGROUND

A. DEFINITIONS

A metric is an assignment of indices of merit to programs in order to evaluate and predict software quality [Ref.1: p.6-2]. The qualities to measure are, at present, subjectively chosen but in general encompass reliability, complexity, efficiency, testability, understandability and modifiability [Ref.2: p.1-3]. The predictive nature of a metric allows it to be used to say "when" to proceed to the next phase in the software life cycle model. Another aspect of the predictive nature of a metric would be for it to provide management with a rough guess of the outcome of a particular path of development, provide an acceptance index, or provide an immediate feedback loop to the implementors while in the unit test phase [Ref.2: p.5]. How the metric is implemented will dictate its primary use from the above selections.

B. SALLIE HENRY'S METRIC

Sallie Henry's metric attempts to measure data flow complexity. It is intended to be used as a tool to establish a module's quality or to enforce particular modularization standards [Ref.2: p.6]. She argues that quality control of software is the result of software reliability and that reliability comes about through well designed modules that do not have complex data flow.

The hierarchical structure of a program should be layered modules. Each layer should function as a virtual machine and be composed of modules. This approach to modularization gives each module characteristics that can be exploited so that each module can be independently developed, more easily comprehended, assembled so that the system is more stable and designed so that the system is a great deal more flexible. This schema of development extols two primary tenets that are stated by D. Parnas in [Ref.3: p.339] and quoted here:

. . . provide the user of a module with all the information to use the module correctly, and nothing more. Provide the implementor of the module with all the information to implement the module correctly, and nothing more.

All this implies that a good design will have high module cohesion, good module strength and low module coupling [Ref.4: p.330].

C. INFORMATION FLOW

Information flow complexity is a twofold process the flow of data within a module and the flow of data external to the module. The measurement of these criteria is dependent on two premises: (1) that there is a capability to measure this data and (2) the data obtained can be used to evaluate software design. The seemingly obvious nature of the first premise runs into problems in implementation and applicability, but if it is accepted that the first deficiency can be surmounted, then the second part remains to be shown as reasonable. Applicability is a debated concept that is still not resolved. It revolves around whether the data gathered is related to the property under consideration. It is

further exacerbated by the human element that defines an environmental bubble and then programs within this bubble. How to measure this bubble without destroying its foundations is the problem of measuring human performance. The problem of what to measure is the problem of applicability.

The more specific the metric's application the less the applicability property is questioned, but, the problem of "what" to measure is still not clearly defined. This thesis will not argue the applicability question because the approach of Sallie Henry is reasonable and the results obtained from the metric appear to adequately encompass the area of data flow complexity. If the reader will accept that the properties measured are related to data flow complexity then the results obtained are also related to complexity.

The second premise is even more thorny. If the data is obtained and it seems reasonable can it be shown to be truly the result of the property under measurement? Any human endeavor will never be clearly and objectively quantified. Thus, the answer to the efficacy of the second premise is, proceed and maybe the amassing of results will eventually show the correlation.

The above analysis is far from a convincing argument to utilize metrics to measure programs however as this thesis was developed the applicability of measuring data flow complexity in order to determine code quality became more apparent although not proven. Nothing will be learned if no attempt is made to measure data flow complexity. This thesis attempts to measure data flow

complexity in the light of learning and the hope that the data gathered will prove the applicability of the process.

Consider first a simple module: a procedure in a structured language. Each procedure defines certain relations between itself and other procedures. These include:

- formal input/output parameters
- function call input and return data
- local data structures
- global data structures

These relations will generate a particular information flow structure similar to a hierarchical tree structure. This tree structure is peculiar to the procedure and will reflect its complexity of structure. It is reasonable to analyze this tree to determine derived calls, local data flow and global data flow.

D. RELATIONS

Some definitions are now in order. Global data flow exists from procedure 1 to procedure 2 if procedure 1 deposits data in the global data structure and then procedure 2 reads that data. Local data flow comprises direct and indirect species. A local direct flow, from procedure 1 to procedure 2, results when procedure 1 calls 2 passing parameters. An indirect data exchange from procedure 1 to procedure 2 exists if procedure 2 calls 1, which returns a value used by 2, or procedure 3 calls both 1 and 2, and passes an output value from 1 to 2.

Figure 1 represents data flow from procedure to procedure or from a procedure into a data structure. Parameter passing within this scheme is represented by the arrows. A hidden data exchange through modification of a variable is represented by the dashed flow arrow. Module A retrieves data from the data structure then calls B passing a parameter; module B updates the data structure. C calls D passing a parameter. D calls E with a parameter and E returns a value to D which is used by D and passed to F. The function of F updates the data structure.

Figure 1. Data Flow Structure

The direct data flows represented are:

A -> B, C -> D, D -> E, D -> F.

These are simply the calls.

The indirect local flows are:

E -> D, F -> A.

The global flows are:

B -> A, F -> A.

Both B and F update the data structure while A retrieves data from the structure.

The implications of data flow for procedure and function calls will be discussed later with derived calls.

The calling notation $A(x) \rightarrow B()$ or $A() \rightarrow B(x)$ is used to connote a data flow transmission from A to B either by direct parameter passing or side-effect. In the first condition the variable x is returned to procedure A and in the second example the variable x is sent to B. A condition that leads the Henry metric to not detect a procedure or function call's data flow (labeled a missed call) is for the condition where $A(x) \rightarrow B()$ and variable x is a returned value from B not modified within procedure A's code. An example of this would be a conditional statement within A that depends on the returned value from function B. The data flow detection problem leads to two key ideas, effective parameters and data utilization.

Calls that are detected by information flow analysis are dependent upon how the information is passed. If the conditions $A() \rightarrow B(x)$ exists where parameter x

is passed to B or condition $A() \rightarrow B()$ where no parameters are exchanged then the calls will not be missed if B receives information in one of the following formats:

- a formal parameter
- a data structure
- a constant
- an actual parameter from a third procedure whose value is modified within A prior to the call to B

An effective parameter will define the call structure in such a way that the data flow will not be missed. It is a parameter that receives information from one of the calling procedure's parameters, a data structure, a constant, or a third procedure's returned actual parameter that is modified within the calling modules structure. What the effective parameter implies is that side-effect data flow is difficult to effectively analyze. Another construct that will cause a missed call is the condition $A(z) \rightarrow B(x)$ where B is a function. This condition means A uses data from B. A uses data from B if (1) B updates a data structure used by A; (2) A receives a constant from B; (3) A receives an output parameter from B; or (4) B updates a return value to A. Thus information flow will be detected if A passes B an effective parameter or if A uses data from B.

Appendix A gives all the rules that are applicable to the data flow relationships. Some notation is now needed to simplify the descriptions that follow.

The form of a relation is $L \leftarrow R_1, R_2, R_3, \dots R_n$; where L is the resultant from the application of the relationships $R_1, R_2, \dots R_n$. An example would be:

$A.D3 \leftarrow A.D1, A.D2, A.constant.$

This series notation represents the code line that begins with D3 below.

```
A()  
begin  
.  
.  
D3 := D1 + D2 + 1;  
end procedure A;
```

In words, the $A.D3$ means procedure A updates data structure $D3$ by first applying relationship $A.D1$ then $A.D2$ and finally $A.constant$. This format shows that data flows into procedure A 's data structure $D3$ from the noted relationships. A thorough discussion of the notation for the relations is given in Appendix A but a short discussion follows to aide in the immediate understanding of Figure 2.

The notation $B.1.I$ defines the first input parameter in the actual parameter list of procedure B and an O would refer to an output parameter. All possible data flow paths are considered even if a $B.1.I$ parameter is not an input parameter. Thus, if procedure B has an output actual parameter in position $B.1$ and the Henry metric attempts to analyze this parameter as an input flow an error condition would result from the attempted evaluation (depicted as $B.ERROR$). $B.NULL$ means that no relationship exists for this parameter or that there is no data flow into or out of the parameter being considered.

Figure 2. Data Flow With Call Structure

Code

```
A()  
begin  
  X := D1 + 1;  
  Y := D2;  
  B(X,Y);  
end;
```

```
B(P,Q)  
begin  
  D3 := P + Q;  
end;
```

Relations Set

```
A1 B.1.I <- A.D1, A.CONSTANT  
A2 B.2.I <- A.D2  
B1 B.1.O <- B.NULL  
B2 B.2.O <- B.NULL  
B3 B.D3 <- B.1.I, B.2.I
```

The relation sets were derived by looking at the data flow into and out of procedure A. That is, since procedure A has no parameters there can only be local data flows into or out of the procedure. These flows are described in terms of the procedure call to B. B.1.I stands for procedure B's first input parameter. This parameter is fed from procedure A's data structure D1 and a constant. Analyzing procedure B's second input parameter yields the A2 relationship. Relationship B1 describes the first parameter in procedure B as an output parameter to procedure A that receives no data for transfer. Relationship B3 describes how the two input parameters to procedure B constitute the data flow to this data structure.

The data flow analysis deals primarily with the analysis of parameters which are direct data flow and indirect data flow as defined above. Modifying Figure 2 and incorporating some local variables will illustrate some more data flow analysis techniques as seen in Figure 3.

Figure 3. Data Flow And Inter-dependent Procedures

Code

```

A()
begin
  X := D1 + 1;
  Y := D2;
  B(X,Y)
end;
  
```

```

B(P,Q)
begin
  R := Q;
  C(P,R,S);
  D3 := S;
end;
  
```

```

C(I,J,K)
begin
  K := I + J;
  J := J + 1;
end;
  
```

Relation Set

A1, A2 same.

```
B1 B.1.O <- C.1.O
B2 B.2.O <- B.NULL
B3 C.1.I <- B.1.I
B4 C.2.I <- B.2.I
B5 C.3.I <- B.ERROR
B6 B.D3 <- C.3.O
```

```
C1 C.1.I <- C.NULL
C2 C.2.O <- C.2.I, C.CONSTANT
C3 C.3.O <- C.1.I, C.2.I
```

In the relation set B1 receives data from procedure C's output parameter. B2 is the same. B3 through B5 describe the parameter list of procedure C. However B5 denotes an error or a condition that is not allowed. That is, the data direction was in error as variable S is an output from procedure C as indicated by relation B6. It should be noted that this relation set building considers all possible data flow paths without regard to the possibility that the parameters could be assigned only particular directions as Ada formal parameters are. Figure 4 shows the effects of a function call.

Code

```
A()
begin
  X := D1 + 1;
  Y := F(X);
  B(X,Y)
end;
```

Figure 4. Data Flow With Function Call

```

F(M) return integer;
begin
  N := D2 * M;
  return N;
end;

```

Relation Sets are changed as follows:

```

A1 F.1.I <- A.D1, A.CONSTANT
A2 B.1.I <- A.D1, A.CONSTANT, F.1.O
A3 B.2.I <- F.O

```

```

F1 F.1.O <- F.NULL
F2 F.O <- F.D2, F.1.I

```

Relation A1 has changed to reflect the analysis of the function call to F. The input to the function call is analyzed as well as its output and any possible modification of its input parameter. This analysis can be seen to cover all possibilities of hidden data transfers except the missed calls described earlier.

E. INFORMATION FLOW STRUCTURE

Once the relation set has been built the relations are sorted alphabetically and stored for future use in the Information Flow Structure (IFS). A recursive algorithm is employed to build the information tree structure for the flow analysis. The IFS is then analyzed to find the derived calls, the local flows and, finally, the global flows.

The IFS will have leaves that are data structures; the root is the initial call from the highest level procedure. Each node of the tree will have the relational form of X.DS, X.O, X.k.I, or X.k.O. See Appendix A for all the possibilities of derived calls. The local flows are described in Appendix A as derived calls. The global flows for a particular data structure are all the possible paths from leaf elements of the form A.DS to the root.

F. INDICES OF MERIT

The calculations of the indices of merit use the idea that the complexity of a module comprises the complexity of the code plus the complexity of the connections of the code to other modules. The formula describing the complexity of a module is

$$\text{Complexity} = \text{length} * (\text{fan-in} * \text{fan-out})^{\text{code index}}.$$

Length is defined as the number of executable statements. The expression fan-in * fan-out represents all the combinatorial possibilities for each input to produce an output. The code index is an exponent that represents the code

difficulty. Nominal code difficulty for operating systems is 2. This index needs more data for other types of programming.

The purpose of this computation is to produce comparative numbers of merit that point out and isolate specific areas within the code that have the potential for problems. A high fan-in/fan-out implies a large interconnection to outside modules. This leads to the assessment that the code in question is most likely not properly modularized or, more succinctly, that the code has more than one function. The other form of data flow is global data flow to data structures. It is calculated as follows:

$$\text{Global flow} = \text{write} * (\text{read} + \text{read_write}) + \text{read_write} * (\text{read} + \text{read_write} - 1)$$

The term write refers to a change to the data within the structure through an assignment statement and a read is an access to the data structure that does not change the data. The identifier read-write is the sum of reads and writes. A high global flow implies overworked data structures and represents a stress point in the program. A stress point is the weak link in the chain. The presence of high flow is not automatically an indicator of poor programming but it is a juncture in the program that is highly susceptible to problems. Once the metric has assembled all the different components, such as fan-in or global reads and calculated the above equations it performs module analysis.

G. MODULE ANALYSIS

Module analysis revolves on the outputs of each of the above equations and their respective components. The numbers generated are symptomatic of certain problems. The analysis is first conducted with the equations output defining the particular categories of problems then the components refine the analysis. Examples of the first level of analysis follow:

A high global flow calculation implies an overworked data structure. These structures are overworked because of the need for continuous accessing. This implies a better decentralized design is in order, that is, distribute the information to the procedures that it serves. A high module complexity index indicates not enough modularization. This number is to be treated with respect but should be analyzed in context with global data flow. Together these indices represent the in's and out's of the modules data. A corrective action based solely on complexity should be avoided. A procedure should be analyzed for singularity of purpose and non-duplication within a module. Simply put, a procedure should be in one place, have one purpose and have minimal external references. These properties are quantified by the Complexity and Global flow metric numbers.

Next the interim cases where one aspect is high and the other component is low. A module with high global flow and low complexity shows poor internal structure. This structure will most likely have excessive numbers of procedures with extensive use of data structures outside the module. Low global flow with

high module complexity implies either poor decomposition into procedures or extremely complicated interface.

H. INTERFACE MEASUREMENTS

Interface between procedures comprise protocol interface, coupling and binding of procedures. Protocol interface from module A to B is defined as those procedures that are not in any other module and which receive information from A for passing to B. Binding is the sensitivity measure between modules, that is, tightly bound modules have a high sensitivity. A tightly bound module is difficult to change without adversely affecting the other module. Coupling is the strength of binding. Figure 5 depicts the interface structure.

Figure 5. Interface Structure

Protocol interface, since it is not symmetrical between procedures, requires the construction of a tabular cross reference table with all possible procedures on both the X and Y axes. The internals of the table are the data flow complexity indexes for one way transmission from each procedure to the other.

Figure 5 shows that binding is sectioned into five components; the number of procedures sending information from A (NSP), the number of procedures receiving information from B (NRP), the number of procedures in the protocol interface (NPI), the number of paths to the interface from A (SPI), and the number of paths from the interface to B (PIR). The Direct Flow paths represented as the outer loops are data transmissions without the interim procedures. [Ref.2: p.85] lists the binding calculations as follows:

$$\text{Binding} = (\text{NSP} + \text{NPI}) * \text{SPI} + (\text{NPI} + \text{NRP}) * \text{PIR}$$

The term $(\text{NSP} + \text{NPI}) * \text{SPI}$ is the coupling strength.

All the direct path binding is calculated by

$$\text{DF Binding} = (\text{NSP} + \text{NRP}) * \text{DF}$$

Modules that are tightly bound are extremely difficult to maintain and modify. This difficulty stems from their lack of independence and the "ripple effect" of changes to one module flowing into the other.

I. THEORY SUMMARY

The purpose of the Henry metric is to provide designers and implementors with a method to quantify the quality of the code that they are developing. The goal is to produce reliable code that is interconnected in as logical a fashion as possible. Information flow complexity produces reliability through enforcement of design rules that lead to well connected code. The measurements will point out lack of functionality, improper modularization, poorly designed modules, poorly designed data structures, system stress points, inadequate refinement, strength of binding, modifiability, missing levels of abstraction and, will produce comparative indices to assess changes.

II. DESIGN CRITERIA

A. INTRODUCTION

The design of the implementation of the Henry metric was a two step process. First, a thorough understanding of the previous work by Neider and Fairbanks [Ref.5: pp.1-164] was undertaken to determine what data were available for importation into the Henry metric. The intention of the study and the basic design issues are (1) modify the output of the parser portion of their thesis to include the necessary data passes to the Henry metric (2) to initially analyze only the Ada package as a unit (3) encapsulate as much of the Henry metric into one Ada package as possible and (4) calculate the necessary Henry metric numbers transparently to the user but present the user with an output that is easily understood.

The underlying premise, of this program, is that the code presented for analysis has been successfully compiled. If the code does not compile and is presented to the parsers it will most likely fail to parse but in the event it does escape detection it will be erroneously analyzed.

The design criteria of encapsulation of the Henry metric was modified during the implementation due to the unwieldy length of the code. The division yielded three packages: one that holds all the global data, another for the analysis portion and a third for the interface to the user. Although this division violated one of

the basic design issues it was necessary in order to achieve solid data transfers between the Naval Post Graduate School computer and the Naval Weapons Station computers.

While the level of what was available from the parsers was being determined the data structures of the Henry metric were being layed out. The data structures and data gathering procedures for the Henry metric were designed to be as simple, yet as flexible as possible. Once the layout of the linked list data structure to hold the raw information for the Henry metric was decided upon, the tedious procedure of inserting the appropriate calls to the Henry package was undertaken. Basically, this reduced to exercising all the possible data flow characteristics from function or procedure calls that the Henry metric could expect to encounter and then ensuring that an appropriate call to the Henry data collection procedure was placed in the Neider/Fairbanks parser.

Next, the analysis procedure was designed. The analysis was separated from the display because computers have very different capabilities in their output devices. The first package analyzes the collected raw data and the second displays the finished, smooth data.

The program is menu driven. It initially gives the user a choice to parse a new program or view old data. If the parse choice is selected the parsers feed both the Henry and the Halstead packages with data. After a successful parse the user is presented with a choice of either viewing the Halstead or Henry metric data. This is when the analysis portion of the Henry metric is called. It is not

until the user decides which data to view is there a distinction made as to how to process the parsed data. This feature was designed for several reasons:

- Use the Halstead metric to refine the code
- then analyze the code via the Henry metric for data flow
- but the user should still have the option to select either metric

The data for both metrics are essentially different as are the purposes for gathering the data but the final goal of this dual metric system is to produce good code.

Finally, the presentation data module was designed. The Halstead and the Henry metric both produce numbers which are essentially meaningless unless a thorough understanding of the particular metric implementation is undertaken. Thus, both metrics, in differing fashions present "help" data to aid understanding of the metric output. These files are both verbally and graphically presented to the user.

The overriding design issue was to modularize the Henry metric as much as possible. The most significant exception to the Parnas' ideal [Ref.4: p.330] are the numerous calls to the data gathering procedure from the parser modules. These calls depend on details of how the data will be analyzed in their sequencing and data passing scheme. A conscientious effort was made to minimize global data and isolate procedures into nearly stand alone modules.

B. SPECIFIC ISSUES

The housekeeping routines of the global package are used to adjust the parsed data into a more palatable form for the analysis and presentation procedures. The output from the parser is stored as a linked list of raw data produced by procedures `WRITE_HENRY_DATA` and `CREATE_NODE`. This data is then analyzed by the `ANALYSIS PACKAGE` for the particular data constructs that represent a data flow. The output is an array of tabulated data that is a set of all the relations necessary for the Henry metric to detect local and global data flow.

The display module presents data in a tabular format or as a graphical representation for relative merit analysis. The intent was for the user to see the effect of changes, or to select a more verbose description of the meaning of the results. The modules that accomplish tabular and graphic displays are separated again because of the varying capabilities of machines. The purpose of these procedures is to provide some form of relative measure to the user so that the improvement or results of a change could be more objectively weighed. The overall purpose of the display modules is to show the data in such a fashion that an intelligent assessment is possible.

C. DESIGN ISSUES

Design issues encountered in the implementation of Henry's metric involve the efficient use of the Ada language's structures and data analysis techniques. Sallie Henry developed a metric process in which the constructs of a particular

language are ignored or not put to specific use. That is, some languages have extremely thorough type and range checking facilities. This is not considered in the basic design of her metric. These powerful features are incorporated in Ada and provide the application programmer more analysis capability.

This design issue concerns the collection of 'all possible paths' data for analysis of actual parameters. The approach taken by Henry is biased to a language where input, output, and combination input output parameters are treated as if they could be modified by the particular procedure regardless of their type. Ada is very picky about the manipulation of formal and actual parameters and goes to great lengths to ensure that parameter consistency is maintained by means of strong type/range checking. The explicit declaration of a parameter type was used to select which component of the complexity equation should be updated. The appropriate fan-in or fan-out number was also correctly updated from default declarations such as the undeclared default formal parameter.

The data analysis technique issue encountered was the need to analyze the data via the IFS. Henry's IFS was designed so that a traversal of its nodes analyzing parent-child pairs will capture all the transitive relational data flows. The transitive flow analysis designed into the present parser will account for the first two layers. The reasoning behind this approach stems from a program review. This review, albeit not extensive, was conducted looking for the predominant use of transitive relations. The review revealed that transitivity is not often used and if used is at most two layers deep. There was little use of deep

transitive constructs. Thus, the design approach selected will detect the majority of the transitive data flow paths without the need for an extensive tree structure. The "normal" program has few transitive relations but the capability to analyze this style of program would add more accuracy to the metric.

Another design anomaly of the metric is the problem of detecting the difference between a function call outside the package declaration and a global data structure manipulation. Ada libraries or packages inhibits the proper analysis of a function call as opposed to a data structure read unless a full compiler's output is available. The present metric was designed so that local function calls (within the package being analyzed) are properly valued but the function calls outside the package are treated as data structure manipulations or more specifically as global data flows.

D. CONCLUSION

The design and implementation phase was driven by the analysis of the Neider/Fairbanks parser portion of their thesis followed by the modularization of the Henry metric. The tradeoffs considered were: the strong typing and range checking of the Ada language, the need for an information flow tree, the need for relative output for the user and, and most importantly the desire to incorporate all of the Henry metric into one Ada package.

III. DESIGN AND TESTING

A. THE EMBEDDED CODE

The previous work done by Neider/Fairbanks had to be modified to output the necessary data for the Henry metric. This was accomplished through embedding calls to the Write Henry Data procedure in Parser0, Parser1, Parser2, Parser3 and Bypass Function (See Appendix C). The writing of the Lexeme, or identifier's name, was controlled by a Boolean that was turned on or off according to the position of the parse of a particular package. The design criteria was to keep the data gathering as simple as possible. If time permitted, a more thorough and sophisticated scheme could be developed. The embedded code was thoroughly tested by two test harnesses that simulated a series of Current Token Records in the form of an input Ada package.

B. THE HENRY PACKAGE

The first package to be implemented was Henry.pkg. It was conceived to be a stand-alone construction that would initialize the data collection process, receive data from the other parsing packages and store the raw incoming data in a linked list. (See Appendix B). Minimal variables and foreign procedures from other packages are used. The Henry package's only "withed" packages are TEXT IO, HENRY GLOBAL, HENRY ANALYSIS and HENRY DISPLAY. This

approach was considered necessary so that the subsequent changes or upgrades would not affect other modules (ripple effect). The design was to implement a basic Henry metric first for Ada packages then to improve and more fully develop the Henry analysis techniques if time allowed. The Main Menu module sequences the user into the analysis and display support packages. The modularization was considered necessary because the analysis and display packages are separate entities and the separation will ensure maintainability.

The initialization is conducted by procedure `Initialize_Henry` and the declaration statements that assign initial values to various Boolean variables. `Initialize_Henry` creates two head nodes, one for the raw data linked list, the other for the procedure or function length records. The raw data linked list storage is a straight line of Henry records. These records have five fields that identify whether this is (1) local or global declaration, (2) the variable/procedure's name, (3) an action class, (4) a parameter class and (5) a pointer to the next record. The action class is comprised of various identifiers that range from procedure type to end parameters declare. Their purpose is to delineate the actions within the parsed program so that the Henry analysis package can look for the data flow. The parameter type field is used to define input, output or combination input output formal parameters. The variable `Henry_Line_count` is purposely initialized within this procedure to draw attention to its initial value. The array of length records is initially a parallel construct not directly tied to the procedure or function it holds the data for. In the analysis package a sequential process is

produced where the records are linked to the data manipulation array. The purpose of the length record is to hold the begin and end line counts of each procedure or function. These line counts are used later to compute the specific modules length for inclusion in the complexity equation.

The receipt of incoming data is accomplished primarily by Write_Henry_Data. This procedure is supported by a boolean Write_Henry_Enable. This boolean turns on or off the recording of the incoming records from the Get_Current-Token_Record procedure. Specifically, the boolean will allow recording only selected data from the incoming record stream selected by the place within the recursive descent parser that the boolean is activated. This control is necessary to pick and choose the data that is critical and to ignore the remainder.

The procedures Create_Node and Clear_Henry_Lexeme support the data gathering scheme. The "in out" pointers within Create_Node serve the purpose of allowing a view of the last record in the incoming stream or to work on the current record. It is arranged so that New_Node points to the newly created blank record and Last_Record points to the just filled in trailing record. Procedure Clear_Henry_Lexeme is necessary because of the way Ada handles strings. Create_Line_Node procedure functions identically to Create_Node.

The incoming data is chosen from within the Bypass_Function and from Parser0 to Parser4 [Ref.5: pp.102-160] by where the calls to the Write_henry_data procedure is positioned. The purpose of this approach is to assure the Henry

metric receives sufficient information but more importantly that the records written into the linked list are delimited in a particular fashion for ease of analysis. There is still considerable data that can be collected for analysis from the parsers but the Henry metric is not to the stage of development where it would be useful. The added depth of information could be used in two areas: analysis and a more informative output from both metrics.

The Write Henry Data procedure selectively enters the field data into the raw data linked list records as dictated by the incoming actual parameters. That is, the incoming data has default settings but if the data is to be ignored then the "null setting" is passed as an actual parameter. This assists in the gathering process. The design of the data gathering modules is such that modifications could be easily implemented. This was purposely designed into them so that upgrades would be fairly painless.

The Henry.pkg was constructed with modularization and maintainability in mind. It was meant to be a stand alone entity that receives data from the Neider/Fairbanks Bypass Function and Parser packages. It performs the functions of initialization, data receipt and data storage besides defining the data structures used throughout the Henry metric packages. There are a number of improvements that could be added to the actual parameter analysis. These improvements all concern the wealth of options Ada provides in parameter passing schemes, such as, aggregates, dot notation to access hidden variables and allocators. Further, the present Henry metric does not analyze the incoming

actual parameters for expressions but the variables are all considered for inclusion in the complexity calculation by the transitivity analysis.

C. HENRY ANALYSIS PACKAGE

The Henry Analysis package comprises three procedures to set up the raw linked list data and a fourth procedure to actually analyze the code for metric calculations. The Analysis procedures are called sequentially from the Henry package and function as support for the Henry package. They operate on the data in sequential discrete steps. They first determine the formal parameters, then search and identify procedures and variables and then determine the metric numbers. The approach used was to nibble each piece of the tremendously complex data flow calculation down into minute sub-steps until all that is left is to simply count the marks on each record for determination of the complexity or global flow metric numbers. This approach removed the necessity for an arduous single pass calculation.

The set up procedures are `CLEAN_UP_HENRY_DATA`, `SET UP HENRY ARRAY`, and `SPRUCE_UP_HENRY_DATA`. A support function, `LOCAL NAME`, assists in the setting-up process. These procedures' end product are two metrics, the complexity metric and the global flow metric.

The Clean Up procedure ensures that all parameter type records have all their fields properly filled. It scans for their parameter lists all the procedures and functions that are declared in the analyzed package. The field of most

importance is the classification of either "in, out or in-out" type parameters. These fields are checked up to the colon delimiter within the formal parameter list and then entered into all `parameter_type` records correctly.

The `Set_Up` procedure scans through the entire linked list setting up another array of pointers to facilitate the analysis process. The `Henry_Array` records have identifier, beginning pointer and `line_length` record pointer entries. This procedure's purpose is to break up the long linked list into another array. It actually does not sub-divide the list it merely arranges an array of pointers into the linked list that delineate each function or procedure. The resulting array is called the `Henry_Array`. The line length record pointers are records that hold the stop and stop line numbers. These records are eventually used to compute procedure/function lengths.

The `Spruce_Up` procedure goes through the `Henry` array data and sorts out the local and global data flow paths. It does this through the use of the `LOCAL NAME` function. This function searches either the `Henry` array for a particular procedure name or the package and appropriate procedure's declaration sections for the variable name in question. Its purpose is to sort out the local procedure or function calls from the global data structure manipulations. It cannot completely solve this problem but defers final resolution to the `Calculation` procedure.

The `Calculate_Metric` procedure will again process the `Henry` array data looking for the final resolution to local procedure or function calls as opposed to a

global data structure manipulation. It proceeds in small increments to finally arrive at the complexity metric calculation and a global data flow calculation. The complexity metric number is arrived at by first considering all the in, out, in-out formal parameters to calculate the fan-in and fan-out numbers. After the initial cut the fan-in, fan-out numbers are incremented upward by the numbers of identified procedure actual parameters that feed these formal parameters and then by the the Transitivity_In and Transitivity_Out functions.

An example of this process would be for procedure A with formal parameters X, Y. First process parameters X and Y for their explicit type adding 1 to fan-in if its an input parameter or 1 to fan-out if its an output parameter. Next process all the assignment expressions looking for a modification of the formal parameter. If procedure A modifies parameter X prior to a call to another function increment the fan-out count by the number of statements after the assignment delimiter. Then go through an analysis of transitivity incrementing fan-in or fan-out accordingly. Finally, call up the appropriate record of Henry_Line_count and calculate the length of the procedure or function in question.

The equation that the process is working toward solving is:

$$\text{Complexity} = \text{length} * (\text{fan-in} * \text{fan-out})^{^2}$$

This equation represents the local data flows within the analyzed procedure. Sallie Henry set the exponent of the bracketed expression to 2 because of her experience with operating system code analysis. This program will continue with

this number until enough data can be compiled to support a change. Once this calculation is done then the global data flows are analyzed.

The global flows are arrived at by first eliminating all other possibilities. Then the remaining choices have to be foreign data flows. This process is started in the Spruce_Up procedure and completed within the Metric_Calculation procedure. The process is used to find whether the data structure is being read from or written to or both.

The equation that the analysis is striving to solve is:

$$\text{Global flow} = \text{write} * (\text{read} + \text{read-write}) + \\ \text{read-write} * (\text{read} + \text{read-write} - 1)$$

This equation represents how and by what means the global data structures are manipulated. The global data analysis procedure goes across procedure or function boundaries whereas the previous complexity metric calculations remain within the particular procedure or function under scrutiny. This across-the-border calculation is accomplished through the text file that is discussed next.

Within the calculation procedure the initial entries for the display package are started. This amounts to constructing a text file of descriptive terms and indices of merit for output in the Display_Package. It also provide a temporary storage bank for the global data information. This across-boundary analysis of

global flows was necessary because of the implications of not being able to detect the difference within the Ada code of an access to a data structure or a function call to a "withed" package.

In summary, the Analysis package is a series of analytical steps. The purpose of these steps is to arrive at the complexity and global flow metrics. These indices and additional data are stored in a text file for output to the user within the Display package.

D. HENRY DISPLAY PACKAGE

The Henry Display package is the user interface portion of the metric program. It provides the user with four different aspects of viewing the analyzed data. The purpose of this package is to show the user the data flow characteristics of the particular parsed input program. The output data will be the fan-in, fan-out, length, complexity, and four global flow numbers. These numbers can be presented in a listing format, viewed with a help file of informative paragraphs or compared by means of the other portions of the analyzed package to gain a relative sense of merit.

The procedures that comprise the Display package are LIST_METRIC_DATA and WRITE_RELATIVE_DATA and GRAPH_RELATIVE. The LIST_METRIC_DATA procedure will output the data file compiled while in the calculation portion of the previously discussed package. It will be a straight listing of information that will be grouped by each

element in the calculation of the complexity or global flow numbers, such as all procedures are grouped under the head of FAN-IN. The purpose of this listing is to show each procedure or functions component figure in the calculation of the final complexity and global figures. If the programmer is in a compile, test, edit, recompile mode of operation this will provide a spotlight on where to improve the data flow "choke- points". These data flow critical points will be seen as either high global flow or high complexity numbers. In short, the LIST_METRIC_DATA is designed for a more sophisticated programmer wishing to edit-and-run and see the results of particular programming style changes.

The WRITE_RELATIVE_DATA display will provide the same format of data but the numbers will have been normalized. Accompanying each number set will be a short narrative keyed to the relationships of the particular numbers. That is, if the user sees a complexity number of 125 beside the procedure X he will be provided with an explanation that that number is not too far out of line in comparison to the other procedures or functions analyzed within this package. The purpose of this approach is to normalize the output numbers to provide a relative comparison for a more user friendly approach to the mysterious metric number generation.

There is an additional procedure within the Display package that provides a complete listing of the raw input data. This procedure will most likely be of no use to anyone except those programmers who are extremely interested in the factors that lead to the particular numbers presented.

The final package for viewing the data is the graphical presentation module. It takes the relative data and manipulates the floating point numbers to achieve a bar chart display.

In summary, the Display package will provide the user with information in a variety of formats so that he can reach a conclusion from relative merit or absolute input numbers. The data flow numbers will point out the critical data flow points within a procedure so that the programmer can better see where to improve or expend the most effort. The purpose of the output data is to show the user where to improve, not how to improve.

E. TESTING

The testing of the design was conducted as the modules were being built and at the integration step prior to the final product. This was accomplished through the use of test harnesses that simulated the particular module's inputs and through test input programs that were hand analyzed to verify the metric's outputs.

The testing of the Henry package was accomplished by gradually building a more thorough test harness as each previous test was successful. The final test harness encompassed over 200 input records that simulated a myriad of token record inputs. The testing of the Henry module presented some difficulty because it is so intimately tied to the parsers. This was overcome by simulating the Bypass Support package as a partial input and the test harness as the balance of

the test vehicle. The package performed well within the test harness and functions adequately within the context of the entire program.

The testing of the analysis package of the Henry metric again was an iterative build of the harness. The testing accomplished after all the Henry metric packages were integrated was accomplished on the same group of programs provided by the NWC programmers to test the Halstead metric integration. The harness testing was comprised of a 50 step program that simulated a package with three independent procedures/functions utilized within its scope. There were intentional references outside the scope of the test harness package to determine if the global call detection scheme functioned properly. In all, the test harness exercised every possible data flow scheme analyzable by the Henry metric including one that would be a missed call. The analysis package performs adequately within the scope of the harness. Testing revealed that the code within the analysis phase was non-reentrant which required the use of a boolean to define the status of the call to the package. This boolean will protect the data structure and effectively make the code reentrant.

The display module was tested with the same driver harness as the analysis package. The results were used to fine tune the package and to debug the problems. The process used was to call the analysis package from the display package and drive the display package with the test harness. This is also how the integrated program performs. The results were adequate from the stand point of the test harness but need some refinement when using the whole program.

The summary of testing would be extensive use of complicated test harnesses. Since a test harness has to simulate all the inputs to a module that the tested code could possibly see during integration, they are difficult to build much less debug. The debugging problem comes from the question 'is it the code or is it the harness?'. The test harness approach is quite fruitful from two orientations: (1) it forces the programmer into a thoroughly understanding his code and (2) the harness construction will lead the programmer into optimizing his code. Why doesn't the programmer already understand his code? He does but the ramifications of a certain approach does not come surface until the design of a test harness is considered. The optimization is driven by the need to get accurate, fast results so that the troubleshoot-repair-compile-troubleshoot regimen can proceed fairly rapidly. This is a real concern with the tremendous

IV. CONCLUSIONS

A. IMPLEMENTATION

The Henry metric was implemented in as modularized a fashion as possible. The intent was to allow for improvements through a more thorough use of the parser's information in AdaMeasure's first revision. Also, certain aspects of the Henry metric were not implemented, but it is now felt that they would add depth to the analysis process. In particular, the first change should be that the Information Flow Structure be added. This tree-like structure will allow the analysis of hidden calls but will still not detect the missed call problem discussed earlier. The missed call problem will most likely only be solved through the use of the Program Counter Register, but this approach defeats the idea of a high level language. The final improvement would be to add analysis of the "withed" packages so that an interface table could be constructed.

The program was incorporated into the previous work by Neider and Fairbanks. Their work was extensive and deserves favorable mention because it made the implementation of the Henry metric considerably easier. The output of the program is still in need of sophistication and improvement. In particular, two improvements are needed: (1) explaining the theory behind the metric and (2) conveying the ideas to the user. For an example, a high global data flow indicates an overworked global data structure. What should the metric present to the user?

The average programmer might not see the relevance of this and would miss the indication that a critical point in the data flow should probably be revised.

B. THE FUTURE OF METRICS

Metrics are tools. They point out areas of weakness. The metric will show a direction to proceed even in the absence of an absolute answer as to the correctness of the analyzed code.

The importance of metrics will grow as the size of programs grow. We do not know how important metrics will become but it does seem clear that there is a need for something that helps improve code quality and is fairly painless to use. The emphasis on "good" code will continue to be in the forefront of the Armed Service's concerns because of their intense involvement in real time embedded programs. These programs present a real challenge for incorporation of changes, improvements or any other form of maintenance programming. The purpose of metrics in this environment would be to point the way to good modularized design.

The metric should be part of the test scenario besides being an integral member of the life cycle of the program. The metric will force quality control without the painful process of formal inspections. The formal process has its place but the metric tool could perform more than the inspection. The metric tool should be incorporated into the test cycle as a meter of improvement. This immediate feedback to the programmer will be beneficial. The manager could

also use the absolute number as a goal for acceptance. This approach will provide the manager with the data needed at decision points in the life cycle of a program. The absolute number could also be tied to the program throughout its life as a measure of improvement or degradation over time. The uses are many, as the reader can see. The importance of the metric cannot be overstated when the future holds programs that will span millions of lines of code.

Metrics are important. They hold out the hope of an automated tool that will guide, interpret, and assess progress for programmers and management alike. I hope that the work of this metric will assist in advancing metrics and the use of the Ada language.

APPENDIX A: INFORMATION FLOW MECHANISMS

MECHANISMS FOR INFORMATION FLOW ANALYSIS

As Sallie Henry so succinctly states:

The information flow analysis takes place in three phases. The first phase involves generating a set of relations indicating the flow of information through input parameters, output parameters, returned values from functions and data structures.

General Format of a Relation

The generation of relations is first prefaced with a quick review of relational format.

$L \leftarrow R_1, R_2 \dots R_{count}$:

Where L may be in any one of the following forms:

1. $P.DS$ P is the name of a procedure and DS the data structure.
2. $P.O.$ P is the procedure name and O is the return value.
3. $P.j.O$ P is the procedure j is an integer representing the formal parameter position, and O is the j th Output parameter.
4. $P.j.I$ P is the procedure, j is an integer representing the j th parameter, and I is the j th input parameter.

R_i may be in one of the following forms:

1. $S.DS$ S is a procedure name and DS is the name of a data structure.
2. $S.O$ S is a procedure name and O is the returned value.
3. $S.j.I$ S is the procedure name, j is the j th parameter and I is the j th input parameter.
4. $S.j.O$ S is the procedure name, j is an integer representing the j th parameter in the list and O is the output parameter.
5. $S.null$ S is the procedure name, null represents no data

6. S.cons. S is the procedure name and constant a value used within S.
7. S.error S is the procedure name and error represents an invalid flow of information through procedure S.

RULES

1. L is of the form P.DS then
this form is used only to generate the relations from procedure P that updates DS with Ri.
2. L is of the form P.O then
This is used only in generating the relations from procedure P that produce an output.
3. L is of the form P.j.O then
This is used when generating the relations that produce an input of the jth parameter in the procedure's formal parameter list. There must be a unique relation for each of P's parameters.
4. L is of the form P.j.I then
This is used when generating the relations for procedure P that produce an input for the jth parameter. Another procedure T calls P to indicate that the jth parameter of P receives the input update.
5. Ri is of the form S.DS then
Procedure S reads information from DS this format is used to indicate a read only.
6. Ri is of the form S.O then
Relations are generated that come from procedure T that are return values to T from S.
7. Ri is of the form S.j.I then
For generating relations for procedure S that indicates S's jth input parameter passes information to L.
8. Ri is of the form S.cons.
Then S causes a constant number or string to flow to L.
9. Ri is of the form S.Null then
This is used to indicate when S does not update a parameter, that is, the parameter was strictly input only.
10. Ri is of the form S.error then
S calls T and one of the parameters to T is an output only thus if S attempts to input a value this would be an error.

ANALYSIS OF CALLS

The following two procedures X and Y, exhibit all possible calling structures in the light of information flow analysis. NP stands for not possible, NC for no calls and the numbers beneath are used for later reference.

The pairs 1, 3, 5, 7, 13, and 15 cannot appear in a flow of data path because for DS's the only assignment and reads allowed are from procedures or functions. The other not possibles stem from input parameters not flowing into DS's and not flowing into output parameters. Entries 2 and 4 indicate X calling Y, receiving information from Y and using this information to update a DS. The rest of the possibilities can be reasoned in like manner except entries 10 and 12, which represent calls via a third procedure. Here procedure Z calls Y and passes the returned value from Y to X. This represents a no call between X and Y but there is a data flow.

TABLE 1.

LOCAL CALL TABLE				
	X.DS	X.O	X.k.I	X.k.O
Y.DS	NP 1	NP 5	Y calls X 9	NP 13
Y.O	X calls Y 2	X calls Y 6	NC 10	X calls Y 14
Y.k.I	NP 3	NP 7	Y calls X 11	NP 15
Y.k.O	X calls Y 4	X calls Y 8	NC 12	X calls Y 16

All data flows from the highest calling structure, eventually being deposited in the data structures. Analysis of the table's data confirms this premise.

MEMORYLESS PROCEDURES

Some procedures keep no record of their data passing or the data supplied. These procedures are used to do housekeeping for memory management, for example, but their analysis for data flow would produce a false amount of data transactions. Another area that these procedures appear in are arithmetic operations that are sometimes duplicated in hardware such as double precision math etc. This discussion leads to the problem that these procedures would be difficult to discern in an automated process. That is, if memoryless procedures are not to be considered in data flow analysis some form of human decision making is required. It should be noted that this is another premise that the automation of the Henry metric is based on. The absolute numbers for the Henry metrics would

TABLE 2.

GLOBAL CALL TABLE				
	X.DS	X.O	X.K.I	X.K.O
Y.DS	NP 1	NP 5	Y flows X 9	NP 13
Y.O	Y flows X 2	Y flows X 6	Y flows X 10	Y flows X 14
Y.K.I	NP 3	NP 7	Y flows X 11	NP 15
Y.K.O	Y flows X 4	Y flows X 8	Y flows X 12	Y flows X 16

be inflated if memoryless procedures are not eliminated from the analysis. In short a memoryless procedure should be removed from the code to be analyzed if a more accurate assessment or if the absolute numbers produced are being used for a comparative study.

APPENDIX B: HENRY METRIC CODE

```
--*****
--
--  TITLE:      AN ADA SOFTWARE METRIC
--  MODULE NAME: PACKAGE HENRY_GLOBAL
--  DATE CREATED: 09 MAY 87

APPENDIX C: MODIFIED PARSERS

[illegible]

CONCLUSION BYPASS FUNCTIONS

This function compares the lexeme of the current token with the token currently being sought by the parser. If the current token type is identifier, then a test is conducted to ensure it is not a reserved word.

```

FUNCTION BYPASS(TOKEN ARRAY ENTRY CODE integer) return boolean is
  CONSUME          boolean = FALSE

```

1. The first step in the process of determining the appropriate level of care for a patient is to conduct a thorough assessment of the patient's medical history, current condition, and social support system. This assessment should be conducted by a qualified healthcare professional, such as a nurse or physician, and should include a review of the patient's medical records, a physical examination, and a discussion with the patient and their family.

2. The second step is to determine the patient's level of functional independence. This can be done by using a standardized assessment tool, such as the Functional Independence Measure (FIM), which evaluates the patient's ability to perform basic activities of daily living, such as eating, dressing, and walking.

3. The third step is to determine the patient's level of cognitive function. This can be done by using a standardized assessment tool, such as the Mini-Mental State Exam (MMSE), which evaluates the patient's ability to think, reason, and remember.

4. The fourth step is to determine the patient's level of social support. This can be done by asking the patient and their family about the patient's living situation, the availability of family members, and the patient's ability to manage their own affairs.

5. The fifth step is to determine the patient's level of risk. This can be done by assessing the patient's ability to manage their own medications, their ability to follow medical instructions, and their ability to recognize and respond to potential hazards.

6. The sixth step is to determine the patient's level of motivation. This can be done by asking the patient and their family about the patient's willingness to participate in their care and their ability to follow through with recommended treatments.

7. The seventh step is to determine the patient's level of financial resources. This can be done by asking the patient and their family about the patient's insurance coverage, their ability to pay for care, and their access to necessary services.

8. The eighth step is to determine the patient's level of cultural and linguistic barriers. This can be done by asking the patient and their family about the patient's beliefs, values, and preferences, and about any language or cultural barriers that may affect the patient's care.

9. The ninth step is to determine the patient's level of legal capacity. This can be done by asking the patient and their family about the patient's ability to make decisions about their care, and about any legal barriers that may affect the patient's care.

10. The tenth step is to determine the patient's level of overall health. This can be done by asking the patient and their family about the patient's general health, their ability to perform activities of daily living, and their ability to manage their own health.

--
-- TITLE:      AN ADA SOFTWARE METRIC
--
-- MODULE NAME: PACKAGE PARSE_R_1
-- DATE CREATED: 17 JUL 86
-- LAST MODIFIED: 30 MAY 87
--
-- AUTHORS:    LCDR JEFFREY L. NIEDER
--             LT KARL S. FAIRBANKS, JR.
--             LCDR PAUL M. HERZIG
-- DESCRIPTION: This package contains thirty-six functions
--             that make up the top level productions for our top-down,
--             recursive descent parser. Each function is preceded
--             by the grammar productions they are implementing.

-- TITLE:      AN ADA SOFTWARE METRIC
--
-- MODULE NAME: PACKAGE PARSER 2
-- DATE CREATED: 18 JUL 86
-- LAST MODIFIED: 30 MAY 87
--
-- AUTHORS:    LCDR JEFFREY L. NIEDER
--             LT KARL S. FAIRBANKS, JR.
--             LCDR PAUL M. HERZIG
-- DESCRIPTION: This package contains thirty-three functions
--              that are the middle level productions for our top-down,
--              recursive descent parser. Each function is preceded
--              by the grammar productions they are implementing.

-- TITLE:      AN ADA SOFTWARE METRIC
--
-- MODULE NAME: PACKAGE PARSE_3
-- DATE CREATED: 22 JUL 86
-- LAST MODIFIED: 30 MAY 87
--
-- AUTHORS:    LCDR JEFFREY L. NIEDER
--             LT KARL S. FAIRBANKS, JR.
--             LCDR PAUL M. HERZIG
-- DESCRIPTION: This package contains thirty-five functions
--              that make up the baseline productions for our top-down,
--              recursive descent parser. Each function is preceded
--              by the grammar productions they are implementing.

-- TITLE:      AN ADA SOFTWARE METRIC
--
-- MODULE NAME: PACKAGE PARSE 4
-- DATE CREATED: 23 JUL 86
-- LAST MODIFIED: 30 MAY 87
--
-- AUTHORS:    LCDR JEFFREY L. NIEDER
--             LT KARL S. FAIRBANKS, JR.
--             LCDR PAUL M. HERZIG
-- DESCRIPTION: This package contains seven functions that
--             are the lowest level productions for our top-down,
--             recursive descent parser. Each function is preceded
--             by the grammar productions they are implementing.
