6 ABSTRACT

Dynamic positioning of a moving platform is analyzed using data from the Global Positioning System (GPS) acquired in Phase II of the Seafloor Benchmark Experiment on R/V Point Sur in August 1986. GPS position determinations are compared to simultaneous Mini-Ranger fixes.

The GPS positions computed using only broadcast ephemeris data were within 20 m from the Mini-Ranger fixes when data from four satellites were used and within 30 m when data from three satellites and a geoidal height constraint were used. It was found that the position accuracy is degraded when data from a satellite reaching culmination is used.

THESIS DISCLAIMER

The reader is cautioned that computer programs developed in this research may not have been tested for all cases of interest. While every effort has been made, within the time available, to ensure that the programs are free of computational and logical errors, they cannot be considered validated. Any application of these programs without additional verification is at the risk of the user.

ACKNOWLEDGEMENTS

The author expresses his appreciation to Dr. Stevens Tucker and Dr. Narendra Saxena for their support and advice in this project, making it a worthwhile learning experience. I would also would like to thank my wife, Conceição and son, Diogo whose love and support encouraged me to complete this work.

I. INTRODUCTION

The Seafloor Benchmark Experiment, a project of the Hydrographic Sciences Group of the Oceanography Department at the Naval Postgraduate School (NPS), was initiated in 1984 with a goal to establish stations on the seafloor in real-time with geodetic accuracy (Saxena, 1982). The first experiment (Phase I), conducted in May 1985, included a configuration of four benchmarks on the seafloor (Spielvogel et al., 1987). Further study indicated a sizeable improvement in the positional accuracy of the inner stations as compared to the accuracy of the outer stations of a larger net configuration (Kumar and Saxena, 1985). For this reason, during the Phase II experiment in August 1986, a nine-station net configuration was used (Kumar, 1986). Three types of GPS receivers and a Mini-Ranger (MR) Falcon system were used to determine the position of the R/V Point Sur.

Keeping the goal of establishing and continuing GPS research at NPS, Brown (1986) established the Texas Instruments 4100 GEOSTAR GPS software, written by the Naval Surface Weapons Center for their CDC Cyber 865 computer, on the NPS IBM-3033 computer. Brown was able to validate the modified software using static position data, but not the KALMN2 program which uses dynamic position data.

The main objective of this thesis is to determine the positions of a dynamic platform using GPS and to compare them with MR Falcon-determined positions. Other objectives were to install software for processing the raw data from cassettes to FIC (Floating-Integer-Character) format, modify the KALMN2 program and validate it using Phase II data. Programs to plot and analyze the continuous ship positions by GPS and by MR Falcon were also written.

The data used in this thesis were acquired during Phase II of the Experiment. The GPS data are limited to those collected by the TI-4100 receiver from NSWC installed on board of the R/V Point Sur. The day chosen for analysis was 16 August 1986, since adequate pitch and roll data are available for that day.

II. INSTRUMENTATION

A. POSITIONING SYSTEMS

1. GPS receivers

During the experiment, the following GPS receivers belonging to several agencies and companies were installed on the R/V Point Sur:

- TI-4100 receiver from Naval Surface Weapons Centers (NSWC)
- TI-4100 receiver from National Ocean Survey (NOS)
- Eagle Mini-Ranger receiver from Motorola, Inc.
- Trimble 4000A from Trimble Navigation

There were shore based GPS receivers at the following stations:

Beach Lab

- TI-4100 from Pacific Missile Test Center (PMTTC)
- Trimble 4000A from Trimble Navigation

Ferrier

- Eagle Mini-Ranger from Motorola Inc.

Dome

- Magnavox Manpack from GPS Joint Program Office.

2. Other positioning System

For navigation and positioning on board were a MR Falcon system from Motorola, Inc., and a Loran-C receiver.

B. OTHER SYSTEMS

An acoustic positioning system from Oceano Instruments to acquire acoustic ranges (Kuo,1985) was installed on the R/V Point Sur; it also gives the position of the ship in relation to the bottom benchmarks (acoustic transponders) and can be integrated with a satellite receiver for computation of their positions using the GPS coordinates of the ship's acoustic transducer.

In order to allow for corrections due to the pitch and roll of the ship, there was a data acquisition system, based on an HP9826 computer, to collect pitch, roll and heading data every second. Due to interfacing problems there was no possibility of logging heading data. The ship's Data Acquisition System (SDAS) collected, among other data, the ship's heading with a sampling period of about 19 s.

C. ANTENNAS AND TRANSDUCER POSITIONS

The antenna of the MR Falcon was mounted on the mast of the ship in order to increase its range. The antenna of the TI-4100 from NOS was installed close to the MR Falcon antenna. All the other GPS antennas were mounted on an elevated wooden table above the ship's laboratories and close to the transducer position (Figure 2.1).

Figure 2.1 Relative positions of antennas and transducer.

III. DATA PROCESSING

A. COORDINATE SYSTEM

1. Parameters

In order to compare the positional accuracies of the TI-4100 GPS receiver with the Mini-Ranger (MR) Falcon, computations were made in a single coordinate system.

Although there was a Doppler survey to find the WGS 72 coordinates of all control stations used, due to the impossibility of setting a station over Dome Ecc, the site for one of the MR Falcon shore stations, the WGS 72 coordinates of nearby station Dome, 68 m away, were obtained. During the Phase II experiment, GPS provided coordinates in the WGS 72 system (Bomford, 1980, Sepplin, 1974), although it converted to WGS 84 on 1 January 1987 (Decker, 1986).

The coordinates of Dome were computed in NAD 27 and then transferred to Dome Ecc. The coordinates of Dome Ecc were converted from NAD 27 to WGS 72 in order to compute directly the ship positions in this system, avoiding the problem of converting each position individually.

The subroutines used for converting geodetic coordinates from WGS 72 to Universal Transverse Mercator (UTM) and vice-versa were written in Fortran and are based on Basic subroutines used by DMA for an HP9826 desktop computer. A cross check was made which revealed a maximum conversion error of 0.01 m, which is well within the accuracy limits of the system and, hence, does not affect the analysis of the data processed.

The following parameters were used:

WGS72

Semi major axis : 6,378,135 m

Flattening : 1/298.26

UTM projection

Central meridian: 123° 00' 00" W

If this package of subroutines is used for any location other than the area of the Seafloor Benchmark Phase II, the UTM parameters must be changed in order to get the correct conversions.

Figure 3.1 Area of the experiment.

2. Coordinates of stations

The two shore stations were located on high points along the coast (Figure 3.1). Their locations and coordinates in WGS 72 are as follows:

Ferrier

Latitude $36^{\circ} 33' 53''.748$ N

Longitude $121^{\circ} 53' 52''.939$ W

Dome Ecc

Latitude $36^{\circ} 18' 20''.897$ N

Longitude $121^{\circ} 54' 00''.594$ W

The elevations of the different antennas were set in the Mini-Ranger receiver and the measured slant distances were converted to appropriate horizontal distances by the receiver system during data acquisition.

B. REDUCTIONS OF POSITIONS TO THE TRANSDUCER

1. Offsets of transducer relative to antennas

Since the two antennas, namely the MR Falcon antenna near the top of the mast and the TI-4100 antenna on the elevated table above the lab on the R/V Point Sur, were at different locations, a common point had to be chosen to compare both systems. The acoustic transducer mounted beneath the hull was chosen as a common point, which was used for further integration with the acoustic data, to compute the position of the Seafloor Benchmarks.

For data reduction there was a need for pitch, roll and ship's heading data. While the existing pitch and roll data were sampled with a period of 1 s, the ship's heading was sampled with a period of about 19 s. Computed headings were tried to improve the rate but tests indicated that the real data, even with a low sampling rate was better than the computed. The method used to compute the heading is described in Section C.3.

The geometric offsets between the MR Falcon, TI-4100 antenna and the acoustic underwater transducer were computed using a right-handed coordinate system centered in each antenna, and having the Y axis oriented towards the bow, the X axis to starboard and the Z axis towards the zenith. Using this convention, all offsets of the transducer are negative. Using the formulas developed in the next section, the corrections for pitch, roll and heading data were computed and applied.

For the MR Falcon positions only horizontal corrections were applied, since the positions are computed in a two-dimensional system. For the GPS positions the corrections were applied to all three coordinates.

For both types of positions the coordinates are converted to UTM, corrected and converted back to WGS 72. For the GPS positions the Z correction is applied to the geoidal height.

The following offsets were measured and computed by Prof. Tucker and Mr James Cherry, and changed to the above format.

Transducer offsets relative to the GPS antenna :

$$XOFF = -4.268 \text{ m}$$

$$YOFF = -2.955 \text{ m}$$

$$ZOFF = -9.505 \text{ m}$$

Transducer offsets relative to the MR FALCON antenna :

$$XOFF = -5.345 \text{ m}$$

$$YOFF = -9.453 \text{ m}$$

$$ZOFF = -16.152 \text{ m}$$

The course was computed in a range 0° to 360° , and the pitch and roll data were stored in a range -90° to $+90^\circ$; following this convention the roll is positive when the port is up and the pitch positive when the bow is down. The sign of roll was changed to conform with the mathematical model described next.

2. Math model

The method to compute the correction to the coordinates is based on a seven-parameter transformation described in Moffitt and Mikhail (1980), so successive rotations of the vector defined by XOFF, YOFF and ZOFF, give the corrections to the coordinates illustrated in Figure 3.2.

The rotation matrices are defined as follows:

$$M_p = \begin{vmatrix} 1 & 0 & 0 \\ 0 & \cos(\text{PITCH}) & \sin(\text{PITCH}) \\ 0 & -\sin(\text{PITCH}) & \cos(\text{PITCH}) \end{vmatrix}$$

$$M_r = \begin{vmatrix} \cos(\text{ROLL}) & 0 & -\sin(\text{ROLL}) \\ 0 & 1 & 0 \\ \sin(\text{ROLL}) & 0 & \cos(\text{ROLL}) \end{vmatrix}$$

Figure 3.2 Rotation of axis.

$$M_h = \begin{vmatrix} \cos(\text{HEADING}) & \sin(\text{HEADING}) & 0 \\ -\sin(\text{HEADING}) & \cos(\text{HEADING}) & 0 \\ 0 & 0 & 1 \end{vmatrix}$$

The orientation matrix is defined by the following equation:

$$M_o = M_p M_r M_h \quad (\text{eqn 3.1})$$

and the corrections are computed by multiplying the orientation matrix by the offset vector, to get the following equations:

$$\begin{aligned} DX = & \text{XOFF} \cos(\text{ROLL}) \cos(\text{HEADING}) + \\ & \text{YOFF} \{ \cos(\text{PITCH}) \sin(\text{HEADING}) + \\ & \sin(\text{PITCH}) \sin(\text{ROLL}) \cos(\text{HEADING}) \} + \\ & \text{ZOFF} \{ \sin(\text{PITCH}) \sin(\text{HEADING}) - \\ & \cos(\text{PITCH}) \sin(\text{ROLL}) \cos(\text{HEADING}) \} \end{aligned} \quad (\text{eqn 3.2})$$

$$\begin{aligned}
 DY = & \text{XOFF} \cos(\text{ROLL}) \sin(\text{HEADING}) (-1.) + & (\text{eqn 3.3}) \\
 & \text{YOFF} \{ \cos(\text{PITCH}) \cos(\text{HEADING}) - \\
 & \sin(\text{PITCH}) \sin(\text{ROLL}) \sin(\text{HEADING}) \} + \\
 & \text{ZOFF} \{ \sin(\text{PITCH}) \cos(\text{HEADING}) + \\
 & \cos(\text{PITCH}) \sin(\text{ROLL}) \sin(\text{HEADING}) \}
 \end{aligned}$$

$$\begin{aligned}
 DZ = & \text{XOFF} \sin(\text{ROLL}) - & (\text{eqn 3.4}) \\
 & \text{YOFF} \sin(\text{PITCH}) \cos(\text{ROLL}) + \\
 & \text{ZOFF} \cos(\text{PITCH}) \cos(\text{ROLL})
 \end{aligned}$$

C. FALCON MINI-RANGER DATA PROCESSING

1. Error of system

The MR Falcon was used during the cruise for navigation and positioning. In post-processing it is used to evaluate GPS data. Since the Mini-Ranger is a system frequently tested and used, its error is known to be ± 3 m (Laurila, 1976; Munson, 1977).

It would be better to have had more than two lines of position (LOP) to allow a minimization of the error in the computation of the Mini-Ranger position and also to allow a smoothing of the data in places where the data gets noisy as was seen in post processing. In Figure 3.3 it is possible to see the areas where the data is noisy and to see the small jumps characteristic of the system.

2. Antenna positions

For computing the antenna positions the coordinates of the shore stations were converted to WGS 72 UTM, and then each position was computed in the WGS 72 UTM projection. The subroutine used to compute the positions was picked from program UCOMPS, a utility package used in the Hydrographic Sciences Group of the Oceanography Department.

3. Heading Calculation

As mentioned previously, the ship's heading was needed to compute the transducer's position, but there was no data available with the 1-s periodicity needed, so headings were calculated from Mini-Ranger data. The calculation of the ship's headings was made during the computation of the two antenna positions and kept on a separate file. These computed headings were affected by the pitch and roll of the ship and also by the noisy data of the Mini-Ranger.

Figure 3.3 Plot of ship's track using MR Falcon data.

Some trials were made using different running averages for smoothing the computed heading in order to get a course close to reality. It was found that the courses obtained, even if filtered by a running average, oscillated and hence were not suitable for this analysis.

4. Transducer positions

The transducer positions were computed using the model described in Section B. The pitch and roll data used were sampled with a periodicity of 1 s most of the time when there was positioning data. The ship's heading was sampled with a periodicity of from 19 s to 1 minute. Although tests were made in order to compute the heading, as stated in the previous section it was decided to use recorded data, constraining the analysis to periods of constant course.

5. Programs. Inputs and outputs

During the development of the programs many more routines were written than mentioned here. In order to make the use of the programs easy, the total number of programs to process the MR Falcon data was reduced to four.

A unique format for the different position files was defined, allowing only one plotting program in which the user must change the title according to the type of positions plotted.

Program: FALCON
Input: Month, day, year, hour, minutes, seconds (date time tag),
code1, range1, strength1, code1, range2, strength2
Output: Listing with date time tag and geographic positions
File with date time tag and geographic positions
File with date time tag and rough course
Source: See Appendix A

Program: COURSE SMOOTH
Input: File with date time tag and rough course
Output: File with date time tag and smooth course
Listing with date time tag and smooth course
Source: See Appendix B

Program: TRANSDUC FALCON
Input: File date time tag and geographic positions of antenna
Output: File with date time tag and geographic positions of transducer
 Optional listing with date time tag and geographic positions
 of transducer
Source: See Appendix C

Program: PLOT
Input: File with date time tag and geographic positions
Output: Plot with track of the ship in UTM projection
Source: See Appendix D

All files are in free format, and, if for by any reason a fixed format is needed, the user should change the programs to get the output desired. The MR Falcon data were originally on floppy disks in HP9816 format. A program was written in Basic in order to convert and write the data onto a 9-track magnetic tape. The transfer of data to mass storage on the NPS IBM mainframe computer and data manipulation were made using existing procedures for the mainframe (Favorite, 1986; Mar, 1984).

The scale and the area of the plot are fixed for the particular area of the Benchmark Experiment but may be changed in the program; thus any proportional size can be obtained by changing the control card as is explained in the manual (W.R. Church Computer Center, 1981).

As the plot program can be used for plotting the outputs of different programs, the title should be changed accordingly, leaving the appropriate lines uncommented. An hour-minute tag is plotted every 5 minutes.

D. GPS DATA PROCESSING

1. Reading the TI-4100 cassettes

a. System configuration

The data from the TI-4100 receiver is recorded on digital cassettes in a format not directly compatible with the existing programs at NPS. To read and decode the data, it was necessary to purchase a MEMTEC cassette terminal (Model 5450XL) and obtain the appropriate software from the Applied Research Laboratories (ARL) of the University of Texas at Austin. The MEMTEC cassette reader was connected to an IBM PC having a hard disk of 20 Mb (Megabytes), a modem and a math co-processor.

Preliminary tests made to verify the software and hardware connections of the tape deck with the IBM PC indicated good results. During the tests it was found that the format of the final output of this package was not the same as defined previously by Scott and Peters (1983) but was in a new format, FIC, where each block is organized in a structured way with control records followed in order by all floating type data, integer type data and character type data. The first program, CON9TR, a part of the library installed by Brown (1986) in the SEF (Standard Exchange Format), was replaced by a new program using the FIC format.

b. Reading cassettes to disk

Each cassette is dumped to disk using the program MFERD. The operation takes about 20 minutes, and the file created fits on one floppy disk which can be kept for raw data backup.

c. Converting the data

The binary image of the cassette is then converted to a FIC format file using the program GS2FIC, which takes about 20 minutes. This format is suitable for processing in the IBM-PC with appropriate software to be developed.

In order to transfer these files to the main frame or other computer, it is necessary to run a program FICFICA that converts the FIC files to an ASCII, format where the data is organized in 80-column records. This operation takes about 30 minutes, and the file created by this program can be dumped to a magnetic tape or sent to a host computer.

The files created by these two programs cannot be stored on a normal floppy disk and were erased as soon as the data was on the mass storage of the mainframe and tested.

d. Transfer to the mainframe

The transfer of the files to the mainframe was done using a micro-computer connected via modem to the main frame. A terminal emulator distributed by the NPS Computer Center, SIMPC, simplifies the transfer of files (Simware Inc, 1984).

Each file, corresponding to one cassette, was sent to a disk. This operation took about 3.5 hours, and sometimes the transfer was stopped in the middle. When this happened the transfer had to be started from the beginning.

Each file has around 15000 lines and occupies about 65% of an A-disk. Using an extra disk every file was converted to a job format in order to transfer it to

mass storage. The data were sent to a member of a partition data set where all cassettes were stored.

2. Conversion of formats

After a study of the FIC format, the input of KALMN2 program, and the program CON9TR, a program was written called CVFICA, which had, after some debugging and improvements, a final form that fulfilled the needs for processing the data for this thesis.

CVFICA decodes each FICA block, producing two files and a listing of warnings and general information. One file contains the data to be processed by the KALMN2 program and the other has the positions computed by the GESAR software installed in the receiver.

In the present version of the program the pseudo-ranges and other tracking information are stored only after the navigational data for the desired number of satellites is in the output file, since this data is needed to compute the positions in the Navigational Mode. It is very easy to change this program to process the data using the precise ephemeris. The program flags as bad the data that belong to a Space Vehicle (SV) whose data does not correspond to the existing SV identification in that tracer. The data are also flagged as bad when the status vector has any value other than zero.

The program is able to convert the following data block types:

- 101 - GESAR Versions 1.0+ Input data,
- 3 - GESAR solutions,
- 6 - Tracking data,
- 8 - Tracking configuration,
- 109 - Navigation Message record as transmitted,
- 9 - De-blocked subframes 1-3 from block 109
- 11 - Receiver error block,
- 13 - Tape header/trailor.

According to the CVFICA program any other block is read and dumped to the listing with a warning saying that the program was not able to handle it. No such warning was found after using the program with data from 10 cassettes.

The listing also indicates when the navigational data for each satellite is received in order to give to the user the status of the constellation of satellites.

As this program outputs the GESAR position solutions and the data to the KALMN2 program into data set files, these must be created prior to running the program.

A control file is used to pass to the program information such as two lines for the title of the listing and the starting date of the GPS week. The starting date allows the conversion of the time tag in seconds to a date time tag. The program does not work with data that crosses the one-week limit.

3. Program information

Program: C VFICA

Input: FICA files without the first two comment lines
Control file with the title and starting date of GPS week
(Appendix J)

Output: File with GESAR solutions
File in NSWC format (input to KALMN program)
Listing with warnings and general information

Source: See Appendix E

4. Computation of positions

a. Problems found

When starting to use the Kalman filter program (Brown, 1986) for processing the GPS data some difficulties were encountered, either due to the replacement of the CON9TR program by an equivalent one or by errors existing in the program KALMN2. The first problems were caused by the different units used in the ARL and NSWC software which were a consequence of the lack of documentation during the development of the program CVFICA; these problems were easily found and solved. The last problems took a long time to find, not only due to the complexity of the program, but also due to the nonexistence of processed data to check the results. A big effort was made in order to correct all errors, but only when two cassettes were sent to NSWC and processed there were all errors removed from the processing. It was found that the last two major errors were due to causes external to the KALMN2 program, one an error in the ARL software that affected the ambient temperature by a factor of 10 and caused an excessive tropospheric correction and the other a bad constant in the control file of the KALMN2 program.

b. Changes made

In addition to the corrections, some changes were made to improve the outputs. Now the program prints a date time tag just prior to all outputs labeled with time tag in seconds of GPS week. A title is printed as a header of the output listing. Other small changes were made to improve the code. All changes were made carefully, and the programs were thoroughly tested.

c. Data processing

After inserting data from ten TI-4100 cassettes into the mass storage, a control file for the KALMN2 program was made (Brown, 1986). For an initial approximate position, the position of the receiver based on the GESAR solutions with the time tag closest to the starting time was used for the data processing. For the receiver time bias, an iterative procedure was used; thus, the data were processed using a value, starting with zero, that was replaced by one listed in the outputs of the KALMN2 program when the computed positions were close to the predicted ones.

Due to the good initial results of the test runs with certain satellite configurations, further tests were investigated for the different types of solutions.

The value of -37 m was used as geoidal height in order to constrain the positions to the geoid when using data from less than four satellites or when forced by the control file. This value was obtained by interpolation on a chart (Blaha et al., 1986) and corrected for the antenna height above sea level, giving a corrected value of -31 m. The control file was set up in such a way as to save the positions on another file. The broadcast ephemeris was used, as the precise ephemeris was not available when the data were processed.

d. Math model

To compute position, the program uses the pseudo-ranges corrected for the various factors affecting them and an eight-state Kalman filter (Brown, 1986).

e. Program information

Program : KALMN2

Input: File in NSWG format produced by the program CVFICA
Control file as defined by Brown (1986)(Appendix I)
Control file with the title and starting date of GPS week

Output: Listing with positions, errors and other information
as selected by the control file
File with time tag in seconds of GPS week, X, Y, Z
and Lat, Lon, HT, both in WGS 72
and the number of satellites used in the solution
Optional file with time tag
and Geometric Dilution of Precision (GDOP) every minute

5. Transducer positions.

a. Procedure

The positions of the transducer were computed using an algorithm similar to the one used with the MR Falcon data. The only difference is that the GPS positions are three-dimensional, so the corrections for all dimensions were computed and applied.

The offsets between the transducer and the antenna and also the format of the input files were different. The program uses the same control file as the program CVFICA in order to compute the date time tag of each position.

b. Program information

Program: TRANSDUC GPS

Input: File with time tag in seconds and WGS 72 coordinates
Control file with the title and starting date of GPS week

Output: File with date, time tag, latitude, longitude and ellipsoid height
Optional listing with above information

Source: See Appendix F

6. Plots

It is possible to plot the track of the ship using either the GESAR solutions or the transducer positions as described before in Section C.5. Track plotting was done in order to give the GPS data coverage and data status. The program to plot is the same one used to plot the positions computed from the MR Falcon data but with the appropriate title (Figure 3.4).

Figure 3.4 Plot of ship's track using TI-4100 data.

IV. DATA ANALYSIS

A. COMPUTATION OF DIFFERENCES

1. Approach

To find the accuracy of the GPS positions in a two-dimensional coordinate system, the observed positions in WGS 72 coordinates are transformed to UTM coordinates and compared with the UTM coordinates of the corresponding MR Falcon positions interpolated for the same time tag. The differences in the coordinates of Mini-Ranger and GPS positions are expressed in meters.

Due to the low sampling rate of the existing course data, only data from steady, straight courses were used for analysis. The data were divided into eleven periods of constant headings, while the data collected during the turns of the ship were deleted. This procedure made it possible to analyze the differences between GPS and Mini-Ranger data during the different courses.

Due to unexpected small differences found for positions computed using data from three satellites, several tests were made using various combinations of solutions. Although for data analysis many combinations were studied, three representative cases are discussed.

Different starting times during processing of the GPS data using the KALMN2 program were used in order to see the effects of the propagation of errors due to the initial noisy data, but the discrepancies were inconsistent. The term "noisy data" is used to refer to the oscillatory behavior resulting from the Kalman filter when the number of satellites changes from three to four or vice versa. The effect of ship's motion on the transfer of antenna positions to two chosen common points, i.e. the acoustic transducer and the GPS antenna, was found to be 0.2 m, which falls within the accuracy limits of GPS and hence is considered negligible for this study.

2. Case studies

The following cases were analyzed:

Case A : Data from four satellites were used or data from only three available satellites and geoidal height constraint for position computation were used.

Case B : Same as case A but using the geoidal height constraint when both three or four satellites were used.

Case C : Same as B but not using data from SV11.

3. Differences obtained

a. Period 1. 19:14 to 19:20 (Cases A and B)

TABLE 1

1	6,8,11	28	31	28-28	31-31 *
74	6,8,9,11	23	30	20-30	28-32

* noisy data

Case A - using four satellites, or
four satellites with geoidal height constraint

Case B - geoidal height constraint in case A

pos - number of consecutive positions computed every second

During the first part of this period, all positions were computed using data from three satellites. In both cases (Table 1) the differences found are in the same range, 24 to 32 m. For the next 80 positions, computed using data from four satellites, Case A lead to values lower than in Case B. The upper limit of the ranges in cases. 31 m, is due to the initial oscillation from the Kalman filter.

The next part of the period is one of noisy data, i.e. changes from four satellites to three and vice-versa. In both cases the positional accuracy is degraded, giving larger differences between GPS and Mini-Ranger positions.

At the end of the period, with continuous data from four satellites and with the exception of one position, the differences are low, reaching 20 m in Case A and 28 m in Case B.

It was found that the use of geoidal height as a constraint for position computations with data from four satellites degrades the computed position. The reason for this is explained in Section 4.B. Noisy data causes oscillations in the observed differences which are due to the Kalman filter.

TABLE 2
SATELLITE VISIBILITY
16 AUGUST 1986

Time	SV6		SV8		SV9		SV11		SV13	
	El	Az	El	Az	El	Az	El	Az	El	Az
19:00	59	2	51	55	24	315	57	156	--	--
19:20	63	21	44	44	32	321	67	147	6	198
19:40	66	45	36	38	39	328	75	124	15	200
20:00	66	72	28	34	48	335	77	78	24	203
20:20	62	96	19	33	57	342	71	74	33	208
20:40	56	115	11	34	67	350	62	36	43	214

The offset of the GPS positions in relation to the MR Falcon positions is in a southeasterly direction (Figure 4.1 on page 40). Also the ship's course is close to the azimuth of SV9 (Table 2), which must be the reason for the successive tracking losses. The GPS antenna is in the shadow of the ship's mast when the satellite is low.

b. Period 2. 19:20 to 19:25 (Cases A and B)

All positions were computed using data from four satellites. There is a nine-second interruption of data in the beginning of the period corresponding to the time needed to change tapes in the receiver during logging.

In Case A the differences range from 17 to 26 m (Table 3). The maximum value was found in the first position after the lack of data. Most of the differences are around 19 m. In Case B the differences range from 23 to 38 m. The minimum value is found after the gap in data. Most of the differences are around 29 m. Visual comparison is possible by referring to Figures 4.2 and 4.3. As before the offset of the GPS positions is in the southeasterly direction.

* noisy data

Case A - using four satellites, or
three satellites with geoidal height constraint
Case B - geoidal height constraint in Case A

pos - number of consecutive positions computed every second

This period is characterized by having noise in different parts of the data and shows great variation in the differences. In Case A, at the beginning of the period

the average differences are 18 m, after the first period of noisy data they reach values of 26 m, and at the end of the period the differences are up to 46 m. In Case B at the beginning of the period the average differences are 30 m. This values changes to 33 m after the noisy data, and at end of the period the differences are up to 38 m. It is possible to distinguish the oscillation in the positions due to noisy data, much more emphasised in Case A than in Case B (Figures 4.4 and 4.5). The offset of the GPS positions is as before in the southeasterly direction.

The successive periods lacking data from one satellite are as before due to SV9, which is still in an azimuth close to the ship's course. The fact that use of geoidal height as a constraint with data from four satellites for computation of positions does not improve the solution is evident in Table 4.

d. Period 4. 19:30 to 19:35 (Cases A and B)

1	6,8,11	38	38	38-38	38-38
81	6,8,9,11	38	41	35-44	40-45

* noisy data

Case A - using four satellites, or
three satellites with geoidal height constraint

Case B - geoidal height constraint in Case A

pos - number of consecutive positions computed every second

This period is characterized by successive changes in the number of satellites used in the computation of positions; the differences are larger than observed in the previous periods. Successive losses of lock on SV9 were the cause for this. In Case A (Figure 4.6) it is possible to see the oscillations of the computed positions when the data are noisy. Improvement in the solutions is seen (Table 5) when we change from three to four satellites; the average differences go from 41 m to 30 m, becoming higher values when only three satellites are available.

In Case B the differences have higher values than in Case A, but the ranges are smaller due to the smaller, noisy oscillations. As before the noisy is caused by the loss of lock on SV9, and the offset in the GPS positions is in the southeasterly direction from the Mini-Ranger positions.

e. Period 5. 19:35 to 19:40 (Cases A and B)

This period has the noisiest data processed, so the differences have greater spread. Although the range between differences is wide, 20 to 68 m in Case A and 29 to 67 m in Case B, the differences are mostly smaller in Case A than in Case B.

In Figure 4.7 we see successive jumps from three satellites to four and vice versa. The GPS positions are south and east of the Mini-Ranger positions. The differences in the northings are almost double of the ones observed in the eastings. The reason for the frequent changes in the number of satellites used is the relatively low altitude of SV9 and an azimuth close to ship's heading, which together with the pitch and roll led frequently to shadowing of the TI-4100 antenna.

f. Period 6. 19:47 to 19:53 (Cases A, B and C)

This period is characterized also by noisy data, but it is for a different reason. Here data from SV8 is rejected during the phase of smoothing it with Doppler data. The observed roll is higher than in previous periods, caused perhaps by the almost 90° change in course. As Table 2 shows, SV8 is setting, having a lower elevation than any other satellite used during this period.

There are no significant differences between Cases A and B, and average differences range from 26 to 30 m. In Case C we see that even lowering the number of satellites to two or three and using the geoidal height as a constraint, smaller differences are obtained than the ones computed with data from SV11 (Table 6). The offset in the positions has no relation to the course of the ship, i.e. it is still in the southeasterly direction, and a small or no time lag exists between the data of the two systems (Figure 4.8).

* noisy data

Case A - using four satellites, or
three satellites with geoidal height constraint

Case B - geoidal height constraint in Case A

Case C - ignoring SV11 but constraining
with geoidal height

pos - number of consecutive positions computed every second

g. Period 7. 19:57 to 20:05 (Cases A, B and C)

In Case B there is an improvement in the positions in relation to Case A. If we refer to previous periods, we see that what is happening is the reverse of what was happening there, i.e. the use of the geoidal height in positions computed using data from four satellites improves the solution. As before, we see that noisy data causes an oscillation in the observed differences but with small amplitudes. Noteworthy are the highly improved positions indicated by a 13-m difference (Table 7).

* noisy data

Case A - using four satellites, or
three satellites with geoidal height constraint

Case B - geoidal height constraint in Case A

Case C - ignoring SV11 but constraining
with geoidal height

pos - number of consecutive positions computed every second

The GPS positions are also south and east of the MR Falcon positions, but the fact of ignoring SV11 causes a decrease in the differences in easting (Figure 4.8).

h. Period 8. 20:07 to 20:13 (Cases A, B and C)

During this period all differences in all cases are smaller than 21 m (Table 8). The higher values are obtained after the computation of a position using fewer than four satellites in Cases A and B, and three satellites in Case C, and are due to the oscillation caused by the Kalman filter. Table 8 shows that constraining the positions computed using data from four satellites improves the solution; the minimum difference reaches only 10 m. Also, ignoring SV11 causes a reduction of the differences, mainly in the easting, and we see that the differences are smaller than in the other cases (Table 8). Figures 4.10 and 4.11 show the improvement in the positions when SV11 is ignored.

1	no data	18	15	11	18-18	15-15	11-11 *
31	8,9,11,13	20	15	11	18-21	15-16	10-11

* noisy data

Case A - using four satellites, or

three satellites with geoidal height constraint

Case B - geoidal height constraint in Case A

Case C - ignoring SV11 but constraining

with geoidal height

pos - number of consecutive positions computed every second

The differences found during this period are similar to the ones obtained in period 8. Table 9 indicates that the differences in all cases are correlated as before. The oscillations are due to the noise in the data from the MR Falcon and not to the GPS positions, which define a smooth and continuous course (Figure 4.12).

DIFFERENCES BETWEEN GPS AND MINI-RANGER POSITIONS

pos	SVs	Avg			Ranges(m)		C
		A	B	C	A	Min-Max B	
9	8,9,11,13	20	16	11	19-21	14-16	9-11
88	8,9,13	11	11	11	10-17	10-15	10-12
206	6,8,9,13	25	25	24	15-26	15-26	15-26

Case A - using four satellites, or
three satellites with geoidal height constraint
Case B - geoidal height constraint in Case A
Case C - ignoring SV11 but constraining
with geoidal height
pos - number of consecutive positions computed every second

During the first tests, the differences were smaller when the positions were computed from three satellites, SV 11 excluded and the ship constrained to the geoidal height, than the ones using four satellites, SV11 or SV6 included. This happened because during data acquisition SV6 was selected to replace SV11, and while the receiver was not locked on the SV6, only data collected from three satellites was good (Figure 4.13).

In Case B (Figure 4.14 or Table 10) constraint of the position to the geoidal height improves the solution where SV11 is used. In Case C (Figure 4.15) we notice a reduction in the differences in the positions where data from SV11 was used. When SV6 replaces SV11, in all cases the differences are larger but of same approximate magnitude.

k. Period 11. 20:30 to 20:37 (Cases A, B and C)

TABLE 11
PERIOD 11, CASES A, B AND C.
DIFFERENCES BETWEEN GPS AND MINI-RANGER POSITIONS

pos	SVs	A	Ranges(m)			Min-Max B	C
			Avg B	C	A		
130	6,8,9,13	35	38	38	35-36	37-39	37-39
287	8,9,13	36	36	36	30-37	30-38	30-38

Case A - using four satellites, or
three satellites with geoidal height constraint
Case B - geoidal height constraint in Case A
Case C - ignoring SV11 but constraining
with geoidal height
pos - number of consecutive positions computed every second

The initial positions were computed using data from four satellites, and after 20h32m10.7s the receiver started to track SV12 in place of SV8, but no broadcast ephemeris data were received during this period. The differences computed using data from three satellites are the same in all cases, but those computed using data from four satellites have different values. Thus in Case A the differences are smaller than in Cases B and C, where the positions are constrained to the geoidal height (Table 11). In all cases the differences in eastings are larger than in northings, contrary to what was happening before; this offset is similar for the other two cases (Figure 4.16).

4. Programs. Inputs and outputs

Two programs written for data analysis are summarized below:

Program: COMPARE POSITION
Input: Control file with period limits (Appendix K)
File with MR Falcon positions
File with GPS positions
Output: Listing with date, time tag, and GPS geographic positions
and differences in UTM coordinates
Source: See Appendix G

Program: COMPARE PLOT
Input: Control file with period limits (Appendix K)
File with MR Falcon positions
File with GPS positions
Output: Plots of tracks using GPS and MR Falcon data
Source: See Appendix H

B. CONCLUSIONS

The results of the data analysis using four satellites with the broadcast ephemeris indicate that the real-time positioning by GPS of a dynamic platform, e.g. a ship, under the best conditions is within 15 m but in most cases 20 m.

Using data from three satellites and constraining the solution to the geoidal height, positional accuracies are within 20 m under the best conditions and 30 m in most of the cases.

It was found that the GPS positions were always southeasterly of the Mini-Ranger positions. Due to lack of sufficient data and due to time limitations, correlation between the geometry of the satellites and ship's heading could not be investigated.

The accuracy of the positions is correlated with the relative motion of the satellites; this was found when SV11 was ignored as in Case C, which improved the solution. If the variations in azimuth and elevation of all satellites are compared for all periods the data was processed, SVs 6 and 11 have variations larger than 110 degrees. while SVs 8, 9 and 13 have variations in azimuth smaller than 35 degrees (Table 2). It

can be seen that both SVs 6 and 11 reach their culmination during the period the data is analyzed. SV6 reaches its culmination around 20:15 and SV11 around 19:50.

When SV11 is approaching culmination, the solution is not improved when the position is constrained to the geoid; after culmination however, application of the constraint improves the solution (Tables 12, 13 and 14).

The degradation in the accuracy of the GPS positions using either SV6 or SV11 is evident in Table 15 where the differences found in these situations are bigger than for positions computed without data from them. It is evident that even in Case C when SV6, with the same characteristics as SV11, is used to compute the position, the differences become larger.

There are some theoretical studies (Landau, 1986) about the selection of satellite configuration in order to get the best results for computed positions. However, with the present data it is not possible to select a best combination, since the data acquisition was limited to a small observational period and a small number of satellites. Currently a way of measuring the effect of the geometry of the satellite configuration is through the analysis of the geometric dilution of precision (GDOP) parameters. These parameters include the position dilution of precision (PDOP), reflecting the dilution of precision in three dimensions, the horizontal dilution of precision (HDOP), reflecting the dilution of precision in two dimensions, the vertical dilution of precision (VDOP), reflecting the dilution of precision in the vertical dimension, and the time dilution of precision (TDOP), reflecting the dilution of precision in time (Milliken and Zoller, 1980). Thus, a low PDOP provides a good geometric configuration. Table 16 lists the observed satellites and their GDOP parameters.

It was found that the position of the antenna is important, and in the case of the NSWCI TI-4100 receiver some error was caused by shadowing due to the ship's mast when the azimuth of the satellites was close to the course of the ship.

The positions used for comparison with the GPS positions are themselves affected by the noisy signal of the MR Falcon positioning system. This problem could be reduced if more than two LOPs were used in the computation of positions.

V. RECOMMENDATIONS

GPS data from other days of the Phase II cruise should be used with the modified programs discussed here to further check our conclusions.

Tests should be made in order to find the reason for offsets in a southeasterly direction and evaluate their correlation, if any, with the geometry of the satellites used.

To test the conclusion that the accuracy depends on the large variations of the azimuth of the satellites, SVs other than SV6 and SV11 should be used.

The relation between satellites' culminations during observations and the accuracy of the positions should be further investigated to provide a criterion for satellite selection.

A better antenna site on the ship should be found to avoid shadowing and to minimize the effects of pitch and roll. Antennas of two similar systems should be installed at both high and low elevations to determine the effects of pitch and roll.

The Kalman filter should be improved to avoid the oscillation when data are noisy. Other algorithms should be implemented and their results compared to the results of the KALMN2 program.

To provide a real-time position computation the KALMN2 program or a similar program should be installed in a transportable computer. A system should be designed to have one computer converting and logging the data, another processing and displaying results, saving them or sending them to still another computer or data recording system, and there should be a master system to control the synchronization of time recorded with all data and to control the flow of information.

Processing of the same data should be done using the precise ephemeris to see how the solution is improved.

Processing in differential mode should be done to see how much the solution is improved.

Comparison of data from other receivers should be done to check which type of receiver provides higher accuracy.

Next an experiment should be designed to obtain point or differential positions in real time for moving platforms (survey ship) with little or no shore support.

To allow better evaluation of the GPS data, positions computed with more than two lines of position should be used as reference.

C
C   AUTHOR: AUGUSTO EZEQUIEL
C   DATE: MARCH 04, 1987
C
C   DESCRIPTION:
C
C       THIS PROGRAMS TAKES EACH POSITION OF THE ANTENNA
C       THE COMPUTED COURSE ( FILTERED OR NOT ),THE PITCH
C       AND ROLL DATA, AND COMPUTES THE POSITIONS OF THE
C       TRANSDUCER, APPLYING THE SEVEN PARAMETER TRANSFORMATION
C       TO THE OFFSETS OF THE TRANSDUCER IN RELATION TO THE ANTENNA
C       CONSIDERED THE CENTER OF COORDINATE SYSTEM AND THEN ADDING
C       THE CORRECTIONS TO THE COORDINATES.
C
C       THE PROGRAM RUNS IN MVS
C
C       I/O SPECIFICATIONS:  SEE END OF THIS JOB.
C
C       THIS PROGRAM IS RESTRICT AS IS TO THE SEAFLOOR BENCHMARK
C       EXPERIMENT
C
C       THE PROGRAM WILL RUN WITH ANY AMOUNT OF DATA ONLY LIMITED TO DISK
C       SPACE
C
C       ANY BLANK LINES WILL TERMINATE THE PROGRAM  IN ERROR

C
C PROGRAM COMPARE POSITION
C
C AUTHOR: AUGUSTO EZEQUIEL
C DATE: MARCH 27, 1987
C
C DESCRIPTION:
C
C THIS PROGRAM TAKES EACH GPS POSITION , FINDS THE
C CORRESPONDING POSITION USING THE MR FALCON, COMPUTES THE
C X, Y AND RADIAL DIFFERENCES AND PRINTS THE DATE TIME TAG
C GEOGRAPHIC POSITIONS AND DIFFERENCES. THIS PROGRAM READS
C THE PERIODS TO COMPARE THE DATA FROM A SEPARATE FILE.
C
C THE PROGRAM RUNS IN MVS
C
C I/O SPECIFICATIONS: SEE END OF THIS JOB.
C
C THIS PROGRAM IS RESTRICT AS IS TO THE SEAFLOOR BENCHMARK
C EXPERIMENT
C
C THE PROGRAM WILL RUN WITH ANY AMOUNT OF DATA ONLY LIMITED TO DISK
C SPACE
C
C ANY BLANK LINES WILL TERMINATE THE PROGRAM IN ERROR
C
C
C
C DOUBLE PRECISION XPOS(3),YPOS(3),TIME(5),SECD,SECH,RATE
C DOUBLE PRECISION DIFX,DIFY,DIST,XNEH,YNEH
C REAL SEC(5),LASEG(3),LOSEG(3)
C INTEGER MONTH(5),DAY(5),YEAR(5),HOUR(5),MIN(5),NSAT
C INTEGER LADEG(3),LAMIN(3),LODEG(3),LOMIN(3),LINE,LOOP,INDEX
C
C INITIALIZATION OF CONSTANTS
C
C SECH=3600.00

APPENDIX J

CONTROL FILE FOR CVFICA PROGRAM.

The first two lines may have a title up to 80 columns. The third line has the month day and year of the starting day of the GPS week. The fourth line has the number of satellites to be used, and other two constants are kept at zero. The last line has the estimate position in WGS 72 coordinates.

The next is the one used for this thesis:

SEAFLOOR BENCH MARK PHASE II
R V POINT SUR 16 AUGUST 1986

8 10 1986

4 0. 0.

-2°39.58 -4340.77 3773.14

APPENDIX K

CONTROL FILE FOR COMPARE POSITION AND PLOT PROGRAMS

The first lines has the number of periods to compare the data. This line must be followed by the same number of lines as periods are to compare. Each line the date time tags from the start and of the periods has the left inferior corner of the area corresponding to each period.

The next is the one used for this thesis:
