ABSTRACT

OPTIMIZATION AND ENHANCEMENT
OF THE PLEXSYS
NETWORK MESSAGING SYSTEM (EMAIL)

by

Gary D. McAlum

Chairman: Dr. Douglas R. Vogel

The Plexsys Network Messaging System (EMAIL) is a computer-based tool that allows users of a network system to communicate with other users through an electronic mail system. EMAIL is a memory-resident network messaging system designed to be used within a planning room environment utilizing a network host to support remote user terminals. The system can be activated by any node on the network to communicate with either another node or with all nodes on the network.

The masters report is divided into three parts: Part I is the User Guide, Part II is the Facilitator User Guide, and Part III is the System Programmer Guide. All program listings associated with EMAIL appear in appendices at the end of the report. *(Keywords: Network Messaging System)*

PURPOSE

This document is intended to be used by personnel who will be actually using the EMAIL system. It does not explain any of the design specifications. This user guide will list the basic hardware/software requirements to run the EMAIL system. It is assumed that the EMAIL system has already been installed and is ready for use. The System Programmer Guide and the Facilitator User Guide discuss in greater detail design specifications and installation procedures.

INTRODUCTION

This document is a guide to the use of the Network Messaging System (EMAIL), a computer-based tool which allows users of the network to communicate with other individuals through an electronic mail system. EMAIL is a package of software programs and procedures designed to enable users of the network to communicate with other users during such sessions as an Electronic Brainstorming Session (EBS). These type of sessions are conducted on a network of personal computer workstations linked together on a local area network (LAN) and controlled by another personal computer called a server. The objective of the EMAIL system is to provide the opportunity for various users to communicate privately or publicly with other users such that the interchange of ideas, information, concerns,

etc., is stimulated for the ultimate benefit of the group's objectives.

With the EMAIL system, communication between users is conducted through the use of individual workstations. Each participant is provided with the EMAIL system as a resident background process as well as two on-line .COM programs. The EMAIL system main menu can be entered or exited at any point without disturbing the user's current screen display. The user is informed of "new mail" by both audio and visual means. Also, the ability to determine who else is logged onto the network is provided by accessing an on-line USERNAME LIST. The EMAIL system is extremely user-friendly in that it is almost totally menu driven with clear message prompts. A user can "broadcast" a message to all users on the system, send individual mail messages, or utilize the SEND.COM function (from the DOS prompt) to send a short "screen note". Mail messages are automatically saved but can be deleted by the user if desired.

The main advantage of the EMAIL system is that it allows the private (or public) communication between users as a support tool to the primary session in progress. The person who initializes the EMAIL system, the facilitator, also has the option of keeping a log of all mail messages sent between users. This log allows for later analysis or research of session effectiveness. Participants will not be aware of the log being kept unless the facilitator informs them.

HARDWARE AND SOFTWARE REQUIREMENTS

The EMAIL system software is run on a local area network (LAN). In this environment there are two machine types, individual workstations and a server machine which controls the individual workstations. The general hardware and software requirements for operating the EMAIL system are listed in tables 2, 3, 4, and 5. Keep in mind these are minimum requirements. Performance can be improved with more advanced computers.

INSTALLATION INSTRUCTIONS

Individual users will not normally be required to install the EMAIL system on their individual workstations. There are two ways in which the EMAIL system can be initialized at user workstations. The first way is the most common. In this method the facilitator prepares and initializes the EMAIL system from the server's Central Control Menu located in the C:\SESSMAN directory. This relieves the user from any action, other than logging a username onto the network. The facilitator, when initializing the EMAIL system from the server, does not have the capability to initialize individual workstations. There are times, such as a late arrival to a session, where a workstation may need to be initialized. The following paragraph provides the input requirements for EMAIL system initialization at an individual workstation on the network.

First, ensure that the EMAIL system is not already loaded into memory. This can be easily checked by pressing a SHIFT/F7. If the EMAIL main menu comes up on the screen, then the only activity which the new or late user needs to accomplish is logging a username onto the system. From the DOS prompt, simply type:

LOGON <ENTER>

This will invoke the program which logs the user onto the system. It will erase any previous username that was assigned to that workstation (figure 1).

If the EMAIL main menu did not come up on the screen then the entire system must be loaded into memory. From the DOS prompt, simply type:

GOMAIL <ENTER>

This command allows the user to logon and loads the EMAIL system into memory. A message will be displayed on the screen when the system is ready for use, see figure 2.

OPERATING INSTRUCTIONS

The following list of items provides information on each EMAIL popup screen and the options available within each. Where appropriate, an explanation is given of the program control. This section assumes that the SHIFT/F7 key sequence has already been entered by the user.

1. EMAIL Main Menu (figure 3)

Keyboard Entry - use the up/down and/or arrow keys to select one of the following options:

-> Send Messages

** passes control to user list
question menu.

-> View Received Messages

** passes control to the view
messages screen.

-> Return to previous screen

** passes control back to the pro-
cess which was running before the EMAIL main menu was
invoked.

The user can also press the ESCAPE key to exit the EMAIL
menu. Program control returns to the previous screen
display.

2. User List Question Screen (figure 4)

Keyboard Entry - press "y" to display a list of
usernames that are currently logged on the system.

** passes control to the username
list.

Keyboard Entry - press "n" to continue on to the
next screen (figure 6).

** passes control to name entry
screen.

3. Username List Screen (figure 5)

Keyboard Entry - press the "ESCAPE" key to exit
this screen.

** passes control to name entry screen (figure 6).

Keyboard Entry - use up/down arrows to select the name of the person you are sending to or "BROADCAST" to send to all users.

** passes control to the screen editor.

4. Name Entry Screen (figure 6)

Keyboard Entry - enter username of the person to whom you are sending the mail message or enter "*" to broadcast.

** passes control to the screen editor.

Keyboard Entry - press <ENTER> to exit this screen.

** passes control to main menu.

5. Screen Editor (figure 7)

Keyboard Entry - type in the desired mail message.

Keyboard Entry - press F1 to display the help screen.

Keyboard Entry - press F10 to send the mail message.

** control passes to main menu.

Keyboard Entry - press ALT/F9 to cancel the

message.

** control passes to main menu.

Keyboard Entry - press INSERT key to toggle between insert and overwrite modes.

6. View Received Messages Screen (figure 8)

Keyboard Entry - press F2 to display next new waiting mail message.

Keyboard Entry - press F3 to reply to the mail message you are currently viewing.

** control passes to the screen editor.

Keyboard Entry - press F4 to forward the mail message you are currently viewing.

** control passes to username question screen.

Keyboard Entry - press F5 to view saved messages.

Keyboard Entry - press F6 to delete the saved message you are currently viewing.

Keyboard Entry - press the ESCAPE key to exit this screen.

** control passes to main menu.

7. Screen Notes (figures 10)

Keyboard Entry - from the DOS prompt, enter SEND to invoke the SEND.COM program (figure 10).

Keyboard Entry - from the DOS prompt, enter SEND and the username of the person you are sending to. For Example:

SEND JOESMITH <ENTER>

Keyboard Entry - from the DOS prompt, enter SEND, username of the person you are sending to, and the message you want sent. For example:

SEND JOESMITH THIS IS THE MESSAGE! <ENTER>

8. Screen Note Display Screen (figure 11)

The EMAIL system will automatically display screen notes to the user. Therefore, the user who received the SEND message only needs to indicate to the system when to remove the message from his or her workstation screen.

Keyboard Entry - press "c" to delete message from screen, see figure 11 for an example of this screen.

For a summary of the main program controls used in the EMAIL system, see table 1.

SPECIAL NOTES

There are two particular situations in which the EMAIL system will not perform as previously discussed. This is due to the safety features built into the software that prevents use of the EMAIL system under inappropriate circumstances.

The first situation will occur if the facilitator has not updated IDFILE.DAT from the Central Control Menu. This situation is recognizable when attempting to use the SEND or READ function from the main menu; program control returns to the previous screen. Until IDFILE.DAT has been updated by the facilitator the user will not be able to access the EMAIL system capabilities.

The second situation will occur when attempting to send a mail message to a user and IDFILE.DAT has been/or is being updated. If the EMAIL system has already accessed and loaded a name from a version of IDFILE.DAT which is no longer valid, any mail sent to that person will simply be disregarded. This is assuming that the recipient is not logged on in the new IDFILE.DAT.

Both of the situations described above are not typical and will rarely, if ever, occur. The primary responsibility of limiting these situations from occurring is placed on the facilitator. He or she must ensure IDFILE.DAT is updated promptly when changes are necessary. For further information on this process, see the Facilitator User Guide.

SUMMARY OF PROGRAM CONTROLS

SHIFT/F7	-	activates EMAIL main menu.
ESCAPE	-	returns control to previous screen.
INSERT	-	toggles between insert/overwrite.
ALT/F9	-	Cancels message being created.
F10	-	sends created mail message.
F1	-	displays help screen in edit mode.
F2	-	displays next waiting mail message.
F3	-	allows reply to viewed message.
F4	-	forwards viewed message.
F5	-	displays saved messages.
F6	-	deletes viewed saved message.
C	-	removes screen note from display.

PURPOSE

This document is intended for those personnel, such as session facilitators, who need to know how to activate the EMAIL system for use. It will describe the sequence of steps necessary to initialize EMAIL for use and explain the location and types of files involved in this process. Specific design details are not discussed. Should this type of information be desired, the reader is referred to the System Programmer's Guide.

INTRODUCTION

EMAIL is a memory-resident network messaging system designed to be used within a planning room environment utilizing a network host to support remote user terminals. The system can be activated by any node on the network to communicate with either another node or with all nodes on the network.

There are two ways to send a message to another node (user). One can utilize the main EMAIL menu to send a mail message of any size, or the SEND.COM function can be used. The SEND function, executed from the DOS prompt, allows a user to send a short "note" of up to 65 characters to another user. The recipient will have this message displayed automatically on his or her screen.

With the typical mail function, a message is sent and the recipient is notified there is new mail and that the EMAIL menu must be entered to read it. EMAIL messages are

automatically saved but can be manually deleted by a user. The user enters the EMAIL main menu by pressing a selected key sequence (SHIFT/F7). Once the user has finished utilizing the EMAIL functions, he/she returns to the saved state of their previously active program: editing, electronic brainstorming, etc. An on-line user list is available that allows the user to see who is logged onto the system. The user selects a username from this list for sending mail messages. When a user receives a new mail message, he/she is notified by means of a popup window and an audible signal. The recipient must enter EMAIL (SHIFT/F7) to read the mail message.

The entire EMAIL system is table driven and based upon the users currently logged onto the network. Off-line utility programs are provided at the central server to build the user table and initialize the network environment for the EMAIL system. An optional log may be selected by the facilitator if desired. This log keeps a copy of all mail messages sent and can be used for later research analysis.

HARDWARE AND SOFTWARE REQUIREMENTS

The EMAIL system software is run on a local area network (LAN). In this environment there are two machine types, individual workstations and a server machine which controls the individual workstations. The general hardware and software requirements for operating the EMAIL system are

listed in tables 5, 6, 7, and 8 at the end of this document. Keep in mind these are minimum requirements.

Once the LAN is activated in a hardware/software configuration as previously described, the EMAIL system can be initialized. The necessary files and their locations are described in tables 1, 2, 3, and 4. As a facilitator you should never have to worry about installing these files. They should already be in place. They are described to give you a better idea of the EMAIL system and to assist you in any troubleshooting that may be necessary.

Each User's A Drive

LOGON.COM	- is used to log user onto the network.
SEND.COM	- allows a user to send screen notes.
EMAIL.COM	- handles the primary mail functions.
ECHECK.COM	- handles all checking and notification.
GOMAIL	- logs user on, and loads EMAIL system.

Table 1

The Server's PUBLIC Directory

EINIT.BAT	- initializes ID file/cleans out directories.
BLDFILE.COM	- initializes IDFILE.DAT with blank usernames.
FLAG.FIL	- used to "Lock" and "Unlock" the user file
GOFILE.DAT	- copies IDFILE.DAT to each MAIL directory.
EMAIL.DUM	- used to initialize the log file.

Table 2

Each User Directory

GOMAIL.BAT - loads the EMAIL system at each workstation.

Table 3

Each User's MAIL Subdirectory

M_MENU.DAT - contains the main EMAIL menu information.
USER.ID - contains the user's id number.
USER.DUM - initializes mail message files.
LOCK.COM - prevents simultaneous access of IDFILE.DAT.
UNLOCK.COM - allows access to IDFILE.DAT.
FLAG.FIL - controls access to IDFILE.DAT.

Table 4

EMAIL SYSTEM INITIALIZATION

Initialization of the EMAIL system via the server is the first and most important step for the facilitator. All files needed by the system are assumed to be in place on the server and each user's disk. Assuming the network has already been activated, the EMAIL system is initialized from the server by the following steps.

1. Bring up the Central Control Menu by typing "GOPLEX".
2. Choose the entry "Activate Group-Support Tools Menu".
3. This will bring up the Group-Support Tools menu;
choose the entry "EMAIL".
4. The Individual Tools Menu will be displayed which has 4 entries as in figure 1.

```
-----  
EMAIL Clean up/Initialize (log not set)  
EMAIL Clean up/Initialize (log set)  
EMAIL System Startup  
Copy IDFILE.DAT to User Mail Directories  
-----
```

Figure 1

If you do not want a log kept, choose the first of the above entries from the menu. If a log is desired, choose the second of the above entries. After your choice has been entered, the system will clean out all old messages and notes from each user's directory/subdirectory. Also, IDFILE.DAT is created and initialized with blank names. This file is also placed in each user MAIL subdirectory. Finally, the system time file is established which is used for timestamping mail messages. The entire process takes about 15 seconds. At the end you will see a message similar to the figure 2.

```
*****  
*                                     *  
*  EMAIL Initialization Complete  *  
*                                     *  
*****
```

Figure 2

The Individual Tools Menu will then be displayed again with the same 4 EMAIL entries as previously described in figure 1.

5. You are now ready to bring up the EMAIL system at each user's station. Choose the entry "EMAIL System Startup". This action will then run a .BAT file at each network station which first makes the user log a valid and correct username into IDFILE.DAT. Once a user has successfully entered a username, they will see a message displayed on their screen similar to figure 3.

```
*****  
*   Name entered into user directory   *  
*****
```

Figure 3

The .BAT file will then load ECHECK.COM and EMAIL.COM into resident memory. At this point a final message will be displayed on each user's screen:

```
*** EMAIL SYSTEM IS NOW RESIDENT. ***  
*** PRESS SHIFT/F7 TO ENTER EMAIL ***
```

Figure 4

A key point to remember is that LOGON.COM will not permit the EMAIL system to be loaded into memory at a workstation until the user has successfully logged on. No input, other than the username, is required of the user in order to initialize the EMAIL system at their workstation.

6. The final step once all users have logged on is to update IDFILE.DAT in each user MAIL subdirectory with the current version in the PUBLIC directory. Once you are in the EMAIL menu, choose the entry which is similar to figure 5 below.

Copy IDFILE.DAT to User Mail Directories

Figure 5

This entry will activate a file in the PUBLIC directory called GOFIELDAT which copies the IDFILE.DAT from the PUBLIC directory into each user MAIL subdirectory. It is important to remember to perform this last task after all users are logged on, otherwise, the EMAIL system will not function correctly. In fact, because each user MAIL subdirectory is initialized with a blank version of IDFILE.DAT, no one will be able to use the EMAIL system at all until the new IDFILE.DAT has been placed in their directories. The EMAIL software is designed to access IDFILE.DAT in each user MAIL subdirectory to maximize performance. The software involved in logging a user onto the network accesses the IDFILE.DAT file in the PUBLIC directory.

SPECIAL NOTES

The advantage of having IDFILE.DAT located in the server's public directory is that it can be updated at any point in a session without disrupting other users. What this means is that a person can come in at the middle of a session and log on without impacting the session. Should a person arrive late, or a change of position is required, you do not need to reinitialize the EMAIL system from the Central Control Menu again. But you will need to enter the Central Control Menu to have IDFILE.DAT copied to each user MAIL subdirectory. There are two possible cases.

1) If the EMAIL system has already been loaded into memory at the workstation simply have the user type "logon" at the DOS prompt. This will then ensure the new username for that workstation is loaded into IDFILE.DAT. (If you are not sure whether the EMAIL system is already loaded simply enter a SHIFT/F7 to see if the main menu appears).

2) If the EMAIL system is not already loaded into memory type (or have the user type) the following command at the DOS prompt:

A> GOMAIL

GOMAIL.BAT will log the user's name into IDFILE.DAT and once this has been successfully done load the EMAIL system into memory. Remember, if you're not sure whether the EMAIL system is loaded in at a particular workstation enter a SHIFT/F7 to see if the main menu appears. Should you not check, there is the possibility of having more than one

copy of the EMAIL system software running in memory. This is definitely not recommended!

In both of the above cases, bring up the Individual Tools Menu and choose the entry corresponding to figure 5. The process of copying this file to all the user MAIL subdirectories takes about 30 seconds. However, this process is transparent to the user and will not affect anyone using the system. The two programs in each of the user MAIL subdirectories, Lock and Unlock, are utilized to prevent interference with the EMAIL system while copying IDFILE.DAT to all user MAIL subdirectories.

The EMAIL system has built-in protection features which prevent the EMAIL system from being inadvertently used if the facilitator has not properly initialized the system. There are two possible situations which could occur.

The first situation is that the facilitator has brought up the EMAIL system at each workstation and users have all logged on. And, either the facilitator has not had IDFILE.DAT copied to each user MAIL subdirectory yet, has forgotten to do this, or the copy process is in progress. Suppose a user enters the EMAIL main menu by pressing SHIFT/F7 and attempts to send a mail message or read a mail message by choosing one of the first two choices on the menu? There is only a blank version of IDFILE.DAT in his/her user MAIL subdirectory at this point. The EMAIL system will not let the user enter into either the SEND or

READ mail function until a "good" copy of IDFILE.DAT is in their user MAIL subdirectory. As soon as the user attempts to enter the SEND or READ mail function the main menu will disappear and the user's previous screen will be displayed. This will continue until a correct version of IDFILE.DAT is in place.

The second situation is where a user is in the process of sending a mail message to a person who is, perhaps, listed in the username list but has since been replaced or another person is logged on at that workstation. Since the user is still accessing information from the old version of an IDFILE.DAT he/she will not know that a new IDFILE.DAT has been placed in their directory. When this mail message is sent it will be simply disregarded. The next time the user attempts to send a mail message the new IDFILE.DAT will be in place.

PURPOSE

This document is intended to be used by personnel who need to know: how to set up the EMAIL system for use on a network, what files are required and where they are located, and how to compile and make changes to the various EMAIL programs.

INTRODUCTION

EMAIL is a memory-resident network messaging system designed to be used within a planning room environment utilizing a network host to support remote user terminals. The system can be activated by any node on the network to communicate with either another node or with all nodes on the network.

There are two ways to send a message to another node. One can utilize the main EMAIL menu to send a mail message of any size, or the SEND function can be used. The SEND function, executed from the DOS prompt, allows a user to send a short "note" of up to 65 characters to another user. The recipient will have this message displayed automatically on his or her screen.

With the typical mail function, a message is sent and the recipient is notified there is new mail and that the EMAIL menu must be entered to read it. EMAIL messages are automatically saved but can be manually deleted by a user. The user enters the EMAIL main menu by pressing a selected key sequence (SHIFT/F7).

Once the user has finished utilizing the EMAIL functions, he/she returns to the saved state of their previously active program: editing, electronic brainstorming, etc. An on-line user list is available that allows the user to see who is logged onto the system. The user selects a username from this list for sending mail messages. When a user receives a new mail message, he/she is notified by means of a popup window and an audible signal. The recipient must enter EMAIL (SHIFT/F7) to read the mail message.

The entire EMAIL system is table driven and based upon the users currently logged onto the network. Off-line utility programs are provided at the central server to build the user table and initialize the network environment for the EMAIL system. An optional log may be selected by the facilitator if desired. This log keeps a copy of all messages sent and can be used for later research analysis.

SYSTEM SPECIFICATIONS

The entire EMAIL system is comprised of four on-line programs. The two primary programs are: ECHECK.PAS and EMAIL.PAS.

Description of ECHECK.PAS

ECHECK.PAS is the memory-resident program responsible for determining when new mail messages are received and for activating the short screen "notes" which may be sent via SEND.COM. ECHECK.PAS has an internal timer that checks for

new mail/notes every 15 seconds. The timer can be changed to any desired time sequence by simply changing a constant in ECHECK.PAS. If there are new mail messages, ECHECK.PAS will notify the user by displaying a popup window and utilizing an audible signal. If there are any screen notes, ECHECK.PAS will display the note automatically and not remove it until the recipient has pressed 'C'.

Description of EMAIL.PAS

EMAIL.PAS is the other main program and is also memory-resident. It controls all the mail functions such as sending and reading mail messages. EMAIL.PAS does not use an internal timer because it can be activated anytime the selected key sequence is entered at the keyboard. Because of all the include files utilized, EMAIL.PAS is the largest of all programs involved in the EMAIL system.

The other two programs in the EMAIL system are: SEND.PAS and LOGON.PAS.

Description of SEND.PAS

SEND.PAS is utilized at the DOS prompt as a .COM file to send the screen notes previously discussed. If you are familiar with the SEND function on the VAX then you will already know how to use this version of the SEND function. They are exactly the same as far as appearances.

Description of LOGON.PAS

LOGON.PAS, as a .COM file, is used when a user is ready to enter into a network session but prior to loading the EMAIL system into memory. It is the critical point because LOGON.PAS is responsible for ensuring that the user enters a valid, unique username into the file IDFILE.DAT. This file is the primary file utilized by the EMAIL system. It is located in the server's PUBLIC directory and each user's MAIL subdirectory. It contains the mapping between user names and actual locations on the network. A blank version of this file is created as part of the initialization process and placed in each user's MAIL subdirectory.

All of the programs utilized in the EMAIL system were coded using Turbo Pascal and inline assembly language. A majority of the memory-resident shell was developed by Lane Ferris, et.al., as "The Hunter's Helper". This shell is public domain software. The current EMAIL system was designed and developed on a network of 16 nodes. It is easily expandable to 32 or more nodes with minimal effort as shall be discussed later.

HARDWARE REQUIREMENTS

The EMAIL system can be used on IBM PC's, or any appropriate compatibles, that are connected via a network server under a local area network configuration. In this environment there are two machine types, individual workstations and a server machine which controls the

individual workstations. The general hardware requirements for a system to run EMAIL are listed in tables 1 and 2. Keep in mind, these are the MINIMUM requirements of each machine type.

SERVER MACHINE REQUIREMENTS

IBM-compatible Personal Computer
128K bytes of main storage
One 360K byte diskette drive
One 10MB hard disk drive
Monochrome or color display

Table 1

WORKSTATION MACHINE REQUIREMENTS

IBM-compatible Personal Computer
128K bytes of main storage
Two 360K diskette drives
Any color display
Any number of workstations

Table 2

EMAIL has two memory-resident programs that are designed to be loaded into each network node's memory thus decentralizing work from the server. The total amount of memory required for the resident portion of EMAIL is approximately 110K bytes of RAM. Any type of disk drive is compatible since neither of the memory-resident programs will access the disk drive again after being loaded into memory. However, LOGON.PAS and SEND.PAS are still located

on the A drive and must be accessible at all times if full use of the EMAIL system is desired. All other files, as well as mail messages and screen notes, are stored on the server in various directories depending on the particular file. For example, all mail and note files are stored in each user's directory in a subdirectory called MAIL. This subdirectory also contains the EMAIL menu data file, user id file, and another file used by EMAIL.PAS. If a log is being kept, the server's public directory will contain this file.

SOFTWARE REQUIREMENTS

For local area network (LAN) operation, a network control program, such as IBM's PC Network, is required plus MS/DOS, Release 2.1 or later. To run the EMAIL system on a network already executing the appropriate network software system there are four locations where certain files must exist. These locations and files are described in tables 3, 4, 5, and 6.

Each User's A Drive

LOGON.COM	-	is used to log user onto the network.
SEND.COM	-	allows a user to send screen notes.
EMAIL.COM	-	handles the primary mail functions.
ECHECK.COM	-	handles all checking and notification.
GOMAIL.BAT	-	logs user on, and loads EMAIL system.

Table 3

The Server's PUBLIC Directory

EINIT.BAT - initializes ID file/cleans out directories.
BLDFILE.COM - initializes IDFILE.DAT with blank usernames.
FLAG.FIL - used to "Lock" and "Unlock" the user file
GOFILE.BAT - copies IDFILE.DAT to each MAIL directory.
EMAIL.DUM - used to initialize the log file.

Table 4

Each User Directory

GOMAIL.BAT - loads the EMAIL system at each workstation.

Table 5

Each User's MAIL Subdirectory

M_MENU.DAT - contains the main EMAIL menu information.
USER.ID - contains the user's id number.
USER.DUM - initializes mail message files.
LOCK.COM - prevents simultaneous access of IDFILE.DAT.
UNLOCK.COM - allows access to IDFILE.DAT.
FLAG.FIL - controls access to IDFILE.DAT.

Table 6

As previously mentioned, the EMAIL system is designed to be initialized from the server. The main menu involved is the Central Control Menu which calls the Individual Tools Menu for EMAIL. This menu is accessed by typing in "U" <ENTER> from the server's SESSMAN directory, or "GOPLEX" <ENTER> at the C:\ root directory. Specific details on how

to initialize the EMAIL system are available in the Facilitator User Guide. However, should you want or need to change the EMAIL menu entries which are displayed in the Individual Tools Menu, simply edit the file EMAIL.LIS. This file is located in the SESSMAN directory.

The previous information summarizes the files necessary to run the EMAIL system on a network. To do any development work on any of the EMAIL programs you need to set up two disks with the appropriate files as described in tables 7 and 8. Batch files such as GOFILE.BAT and EINIT.BAT are not listed in either table. These can be copied to either disk if changes are necessary. However, keep in mind the space limitations of both disks.

Development Work Files: A Drive

TURBO.COM	-	the Turbo Pascal compiler.
EMAIL.PAS	-	main EMAIL functional program.
ECHECK.PAS	-	handles checking/notification.
LOGON.PAS	-	logs user onto system.
SEND.PAS	-	sends screen notes at DOS prompt.
BLDFILE.PAS	-	initializes IDFILE.DAT

Table 7

Development Work Files: B Drive

STAYSUBS.420	- contains necessary subroutines.
STAYWNO.341	- creates windows.
STAYI16.410	- handles interrupt 16 calls.
STAYI13.410	- handles interrupt 13 calls.
STAYI21.410	- handles interrupt 21 calls.
STAYI8.420	- handles interrupt 8 calls.
STAYI28.410	- handles interrupt 28 calls.
STAYSAVE.420	- saves operating system structures.
STAYRSTR.420	- terminates and stay resident.
CLKI8.410	- used to set up an internal timer.
BLDMSG.INC	- builds the mail message being sent.
GET.INC	- reads new or saved mail message.
MENU.INC	- displays main EMAIL menu.
STRMENU.INC	- displays username list.
LOCK.PAS	- controls access to IDFILE.DAT.
UNLOCK.PAS	- used to allow access to IDFILE.DAT.

Table 8

Once you have two disks with the appropriate configuration of files as described above, you can use Turbo Pascal as you normally would to make any changes. When compiling any of the Pascal programs you need to ensure a .COM file is created by entering the options menu. Additionally, when compiling ECHECK.PAS set the MAXIMUM Segment size to 275 and the MINIMUM Segment size to 275. This is done while in the options menu prior to compiling. When compiling EMAIL.PAS set the MAXIMUM Segment size to 400. The MINIMUM Segment size will already have the default value of 400. These values are necessary because they control the stack/heap size while running the EMAIL system. Should you decide to manipulate these values you

may encounter a run-time FF error, meaning you ran out of memory.

DESIGN DETAILS

Only structures applicable to MS/DOS or Turbo Pascal were used. The memory-resident shell does extensive manipulation on the operating system structures. User mail messages are sequentially numbered files (ie. USER1.N1, USER1.N2, USER1.N3, ..., USER16.N1, USER16.N2, ...,) for new mail messages and for saved messages (ie. USER1.O1, USER1.O2, ..., USER16.O1, ...). When a new mail message is created, it is added as the next sequentially numbered message in the new mail queue. Once the new mail message has been read it is automatically saved with the new extension, such as USER5.O3. The user only has the capability to delete saved messages, not new mail messages.

With regards to the screen notes using SEND.COM from the DOS prompt there is no queueing function! When the note has been created, it is placed in a temporary holding file in the user's MAIL subdirectory called TEMP.MES. SEND will check the destination directory to see if a file called USERx.MES ($x = 1, 2, \dots, 16$) already exists. If it exists, it means another person's note is waiting to be read. This will cause a delay for the sender until that other note has been read. Theoretically, since ECHECK checks for new mail and notes every 15 seconds the worse possible situation would be where the user sends a screen

note and there is another note already there. If ECHECK has just finished checking the receiver's directory the sender would be held in a 15 second loop until ECHECK comes back around and displays the waiting message. This may not seem as efficient as utilizing a queueing function but the primary traffic will be mail messages through the normal EMAIL functions. By not utilizing a queueing function, the overall complexity of the SEND function was kept to a minimum. A potential timing problem could occur if two users with sequential locations on the network send a screen note to the same destination at the exact time. One of the screen notes might be overwritten. The probability of this type of situation occurring is extremely low.

IDFILE.DAT

A key point to be discussed is in relation to the file which is the main interface between the EMAIL system and the local area network on which it is running. Remember that IDFILE.DAT contains the username of each user and their "location" on the network. As already explained IDFILE.DAT is accessed by all users when logging onto the network. When all users have logged on, the facilitator then has a copy of IDFILE.DAT placed in each user's MAIL subdirectory. Therefore, keep in mind that LOGON.PAS accesses IDFILE.DAT in the PUBLIC directory and EMAIL.PAS and SEND.PAS access IDFILE.DAT in the individual user MAIL subdirectories.

When logging on, IDFILE.DAT must be accessed by all users. In order to allow access by multiple users of this file (in the PUBLIC directory) a "Lock" and "Unlock" procedure has been implemented in LOGON.PAS. The Lock procedure is called before any code within a program that accesses IDFILE.DAT. It first looks in the server's public directory to see if a file called FLAG.FIL exists or not. If it does, this means that IDFILE.DAT is available for use. Procedure Lock then renames FLAG.FIL to TEMP.FIL to prevent other programs from accessing IDFILE.DAT. This action alone was not enough to prevent simultaneous "collisions" from occurring. Turbo Pascal compiler directives have been added around the code which attempts the renaming of FLAG.FIL. This prevents a run-time error from occurring should two or more programs try to rename the file. Procedure Unlock is placed after the code which accesses IDFILE.DAT to "release" it for other programs to access. Unlock simply renames TEMP.FIL back to FLAG.FIL.

Similarly, the same procedures are used in EMAIL.PAS and SEND.PAS. Although these programs access their own personal copy of IDFILE.DAT, there are times when simultaneous access of IDFILE.DAT might occur. For example, the facilitator can copy new versions of IDFILE.DAT to each user MAIL subdirectory if a person logs on late or a change of seating arrangement occurs. The batch file, GOFILE.BAT, also utilizes programs LOCK and

UNLOCK which are the same as the procedures LOCK and UNLOCK.

Special Programming Notes

Currently, ECHECK.COM is set for a 15 second interval. In other words, every 15 seconds it executes the check for new mail messages and screen notes. This time was purely arbitrary and can be adjusted by changing the variable called TIMER_TIME.

To enter the main EMAIL system menu, the user must press SHIFT/F7. This can also be easily changed if desired. A variable in EMAIL.PAS called OUR_HOTKEY contains the value corresponding to SHIFT/F7.

As mentioned before, the EMAIL system was designed and developed on a local area network of 16 nodes. However, to expand the operating capacity of the EMAIL system is quite simple. The first step is to change a constant called NODES to the desired number, such as 32, in each of the following programs: BLDFILE.PAS, LOGON.PAS, SEND.PAS, ECHECK.PAS, and EMAIL.PAS. The next step is to modify EINIT.BAT. The appropriate code for extension to 32 nodes is already present in EINIT.BAT but is commented out. Simply remove the lines preceded by REM, which designates a comment in BAT files. The final, but critical, step is to modify the user table in SEND.PAS and EMAIL.PAS. The appropriate code is already present to expand to 32 nodes but is commented out. Simply remove the comment brackets

and append that code to the end of the user table. Remember, the additional nodes must have the same user directories on the server and contain the necessary files as mentioned previously.

System Limitations

Once loaded the EMAIL system cannot be removed from memory except by rebooting the computer station that it is running on. If you have to reboot a particular station none of the ordinary initialization done on the Sserver has to be done as this would severely disrupt the rest of the users logged on. Simply, reboot the particular machine and enter the following command.

A> GOMAIL <ENTER>

Mark and Release

There are a couple of public domain programs which can be used to remove programs from memory. They are called MARK and RELEASE. Prior to loading ECHECK and EMAIL, you would enter MARK at the terminal. When you want to take ECHECK and EMAIL out of memory, you would enter RELEASE. A potential problem arises from the fact that when a RELEASE command is entered, any memory-resident programs loaded into memory after the last MARK command will be released. If you can always ensure that ECHECK and EMAIL are the last programs loaded after MARK then this will not present a problem. But, if this is not always the case

then you should consider carefully whether or not you want to use the MARK and RELEASE commands.

APPENDIX A
PROGRAM LISTING
of
EMAIL.PAS

```

(#####)
$
$ EMAIL.PAS      GARY MCALUM      August 1987
$
$ PROGRAM DESCRIPTION:
$
$ EMAIL is a memory-resident network message system designed to be used
$ within a planning room environment. This program can be activated by
$ any network node to send or receive messages to a specific node or all
$ nodes active on the network. When a user receives a message, he is
$ notified by means of a another memory-resident program called ECHECK.
$ EMAIL is table driven and is based upon the users currently on logged on
$ the network. Messages sent on the system contain both the sender's and
$ and receiver's names as well as a time stamp on when the message was
$ sent. An optional log may be created at initialization that allows all
$ messages sent on the system to be logged and kept for later analysis.
$
$ INPUT/OUTPUT FILES:
$
$ (1) USER.ID      : contains the unique user number in ASCII (1-16)
$ (2) USER.DUM      : used to write a blank screen for the new message
$ (3) USERX.N#      : X = user#; # = 1,2,3...; new mail message
$ (4) USERX.O#      : X = user#; # = 1,2,3...; old mail message
$ (5) M_MENU.DAT    : a menu file for the main EMAIL program menu
$ (6) IDFILE.DAT    : the user table, created each system init
$ (7) TIME.FIL      : contains the base sys time, replaced each sys init
$ (8) FLAG.FIL      : is used by procedures Lock and Unlock; for IDFILE
$ (9) EMAIL.LOG     : an optional log file to store mail msg interaction
$
$ PROGRAM REQUIREMENTS:
$
$ Memory required is approximately 82k bytes of RAM. Any type of disk
$ drive is compatible since the program is loaded directly in memory and
$ does not access the disk containing the source program afterwards.
$ EMAIL was developed and tested using MS/DOS Version 3.1 and TURBO Pascal
$ Version 3.0. This program should be assembled as a COM file with mini-
$ mum dynamic memory to set 0400 and max. dynamic memory set to 0400. This
$ ensures enough memory is allocated to the heap to avoid collisions while
$ limiting the amount of memory reserved for the heap.

APPENDIX B
PROGRAM LISTING
of
ECHECK.PAS

```

(*****
$
$ ECHECK.PAS          GARY MCALUM          August 1987
$
$
$ PROGRAM DESCRIPTION:
$
$ ECHECK is a memory-resident program which is used in conjunction with
$ another program called EMAIL. Together they form the network messaging
$ system for PLEXSYS. ECHECK scans each user's directory, every 15 seconds,
$ to see if there is any new mail. If so, it notifies the user with an
$ audible and visible signal. In addition, this program performs the
$ function of checking for screen messages, also called "notes". These
$ notes are created and sent from the DOS prompt by a program called SEND.
$ Once the note has been placed in the user's directory with the extension
$ .MES then this program will notify the receiver by an audible signal
$ and by displaying the actual note on the screen. The user has to press
$ C to remove the message.
$
$ INPUT/OUTPUT FILES:
$
$ (1) USER.ID       : contains the unique user number in ASCII (1-16)
$ (2) USERX.MES      : X = user #, .MES file is on-screen note
$ (3) USERX.N#       : X = user #, # = 1,2,3,..., new mail message
$
$ PROGRAM REQUIREMENTS:
$
$ Memory required is approximately 30k bytes of RAM. Any type of disk
$ drive is compatible since the program is loaded directly in memory and
$ does not access the disk containing the source program afterwards.
$ ECHECK was developed and tested using MS/DOS Version 3.1 and TURBO Pascal
$ Version 3.0. This program should be assembled as a COM file with mini-
$ mum dynamic memory set to 0275 and max. dynamic memory set to 0275. This
$ ensures enough memory is allocated to the heap to avoid collisions while
$ limiting the amount of memory reserved for the heap.
$

APPENDIX D
PROGRAM LISTING
of
SEND.PAS

```

(*****)
($ This program is used to send an "on-screen" message to any user on the $)
($ the network. It can only be invoked from the DOS prompt. After the $)
($ user types "SEND", they will be prompted for the receiver's username. $)
($ This name is checked against IDFILE.DAT to see if it is valid. Once a $)
($ name is correct and valid, the user will be prompted for the message $)
($ which cannot exceed 65 characters in length. After the message has been $)
($ created the program places the message into a temporary file called $)
($ TEMP.MES which is located in the user's subdirectory MAIL. The program $)
($ will then attempt to place it in the receiver's MAIL subdirectory if no $)
($ other message is being read. Note: there is no queueing function. The $)
($ program will simply loop until there is an available slot to place the $)
($ message. $)

APPENDIX J
PROGRAM LISTING
of
MENU.INC

```

((((((((((((((((((((((((((((((((((((((((((((((((((((((((
$ MENU.INC (PREVIOUSLY USE_MENU)      Bill Saints      $
$                                     $
$ (modified by Gary McAlum for EMAIL, July 1987      $
$                                     $
$ Displays a menu by calling up a file created by MENU_MAKER.COM.$
$ When an item is selected by pressing ENTER, the number of the $
$ the item is returned. The calling program should include this $
$ file and make the following declarations:           $
$                                     $
$   Var                                           $
$     var1 : WinlstHdr;                          $
$     var2 : integer;                            $
$                                     $
$ The menu file should be read at the beginning of the calling $
$ program using the following statement:           $
$                                     $
$     var1 := Read_Menu_File(menu_filename)        $
$                                     $
$ The menu is then displayed using the following statement:    $
$                                     $
$     var2 := Use_Menu(var1,bor_type,bor_bgclr,bor_fgclr,false); $
$                                     $
$ - bor_type sets the border style:                $
$     0=solid,1=single line,2=double line, 10=hatched $
$ - bor_bgclr and bor_fgclr are the border colors $
$ - boolean parameter...true=menu stays on screen after choice $
$     false=menu disappears after choice           $
$                                     $
$ var2 is the number of the menu item that was chosen when the $
$ user pressed ENTER.                                $
$                                     $

APPENDIX K
PROGRAM LISTING
of
SEND.INC

```

({})
$ SEND.INC (EDITOR.INC PREVIOUSLY)
$ Bill Saints
$
$ (modified by Gary McAlum for EMAIL, July 1987
$
$ This callable editor can be called into any window. It creates
$ a window of the specified color and location. The window is
$ removed when you exit from the editor. The editor contains a
$ help screen that lists the cursor-control and editing commands.
$
$ The following parameters must be set prior to the call:
$
$      x1,      - left column of window ( >1 )
$      y1,      - top line of window ( >1 )
$      x2,      - right column of window ( <80)
$      y2,      - bottom line of window ( <25 )
$      back,    - background color of window
$      fore,    - color of text in window
$      fback,   - bgd color of border (-1 = no border)
$      ffore   : integer, - color of line in border
$      edt_file: St_66,  - name of file to be edited
$      Bor     : integer, - # of border lines (1,2)
$      outpt   : integer; - 1=rewrite file, 2=append
$
$ The procedure RE_RITE_TXT(filename) can be called after exiting
$ the editor to write the edited text to a file. The procedure
$ APP_RITE_TXT can be called to append the edited text to a file
$
({})

#####
$ FASTWRITE.INC $
$ Prints a string much faster than writeln. $
$ $
$ The colors are controlled by passing appropriate $
$ integers in the attrib parameter: $
$ Values from 0 to 15 will give you a black background $
$ and the foreground color associated with the usual $
$ numbers. From 16 to 31 will give you a blue back- $
$ ground with the foreground colors cycling through $
$ again. And so on through 127. For example, passing $
$ 14 in attrib will give you black background and $
$ yellow foreground. The value 30 will give you blue $
$ background and yellow foreground. $
$ The numbers from 128 through 155 will repeat the $
$ above sequence but will produce blinking text. $
$ An easy way to calculate the number you need for $
$ a particular combination of background and foreground $
$ colors is to use the following formula, substituting $
$ numbers given in the Turbo Manual for the colors: $
$ $
$ (background-color $ 16) + foreground-color $
$ $

of
EINIT.BAT

```

echo off
ren #####
ren $
ren $ EINIT.BAT - This batch file will do several things needed to $
ren $ initialize the network EMAIL system. The most important task $
ren $ is to build the file called IDFILE.DAT. This is done by exe- $
ren $ cuting BLD_FILE.COM. This is a user-friendly, menu driven pro- $
ren $ gram which is self-explanatory. After building the file, it is $
ren $ copied to the subdirectory MAIL which is located in each user's $
ren $ directory. In addition, all extraneous messages and temp files $
ren $ are deleted also. These files are only related to EMAIL and do $
ren $ affect any other part of the network. Presently, this batch file $
ren $ is set up to initialize 16 user directories. If the network is $
ren $ expanded to 32 nodes, simply remove the commented code out, which $
ren $ is pointed out below. This file also initializes the system time $
ren $ file by calling 6TIME.COM from the SESSMAN directory. $

rem #####
rem #
rem # 60FILE.BAT
rem # This bat file is used to copy IDFILE.DAT to each user's MAIL
rem # subdirectory. IDFILE.DAT provides the mapping between username
rem # and location on the network. It is used by the EMAIL system
rem # to allow communication between users but relieve users from
rem # having to know the actual location of the receiver on the net-
rem # work. This bat file is called from the EMAIL Individual Tools
rem # menu located in the SESSMAN directory. Before copying a file to
rem # the user's mail subdirectory, a procedure LOCK is called to pre-
rem # vent the user's EMAIL program from accessing IDFILE.DAT while it
rem # is being updated/copied. After the copy is done a procedure
rem # UNLOCK is executed to allow the user's EMAIL system to access the
rem # updated IDFILE.DAT.

```

Apologetically mangled by Lane Ferris

For MS-DOS version 2.0 or greater, Turbo Pascal 1.0 or greater.

Thanks to Marshall Brain for the original idea for these routines.
 Thanks to John Cooper for pointing out a small flaw in the code.

These routines provide a method for Turbo Pascal programs to trap MS-DOS interrupt 24 (hex). INT 24h is called by DOS when a 'critical error' occurs, and it normally prints the familiar "Abort, Retry, Ignore?" message.

With the INT 24h handler installed, errors of this type will be passed on to Turbo Pascal as an error. If I/O checking is on, this will cause a program crash. If I/O checking is off, IOResult will return an error code. The global variable INT24Err will be true if an INT 24h error has occurred. The variable INT24ErrorCode will contain the INT 24h error code as given by DOS. These errors can be found in the DOS Technical Reference Manual.

It is intended that INT24Result be used in place of IOResult. Calling INT24Result clears IOResult. The simple way to use INT24Result is just to check that it returns zero, and if not, handle all errors the same. The more complicated way is to interpret the code. The integer returned by INT24Result can be looked at as two bytes. By assigning INT24Result to a variable, you can then examine the two bytes: Hi(<variable>)-1 will give the DOS critical error code, or (<variable> And \$FF00) will return an integer from the table listed in the INT24Result procedure (two ways of looking at the critical error); Lo(<variable>) will give Turbo's IOResult. A critical error will always be reflected in INT24Result, but the IOResult part of INT24Result will not necessarily be nonzero; in particular, unsuccessful writes to character devices will not register as a Turbo I/O error.

INT24Result should be called after any operation which might cause a critical error, if Turbo's I/O checking is disabled. If it is enabled, the program will be aborted except in the above noted case of writes to character devices.

Also note that different versions of DOS and the BIOS seem to react to printer errors at vastly different rates. Be prepared to wait a while

for anything to happen (in an error situation) on some machines.

These routines are known to work correctly with: Turbo Pascal 1.00B PC-DOS;
Turbo Pascal 2.00B PC-DOS;
Turbo Pascal 2.00B MS-DOS;
Turbo Pascal 3.01A PC-DOS.

Other MS-DOS and PC-DOS versions should work.

Note that Turbo 2.0's normal IOResult codes for MS-DOS DO NOT correspond to the I/O error numbers given in Appendix I of the Turbo 2.0 manual, or to the error codes given in the I/O error nn, PC=aaaa/Program aborted message. Turbo 3.0 IOResult codes do match the manual. Here is a table of the correspondence (all numbers in hexadecimal):

Turbo 2.0 IOResult	Turbo error, Turbo 3.0 IOResult
00	00 none
01	90 record length mismatch
02	01 file does not exist
03	F1 directory is full
04	FF file disappeared
05	02 file not open for input
06	03 file not open for output
07	99 unexpected end of file
08	F0 disk write error
09	10 error in numeric format
0A	99 unexpected end of file
0B	F2 file size overflow
0C	99 unexpected end of file
0D	F0 disk write error
0E	91 seek beyond end of file
0F	04 file not open
10	20 operation not allowed on a logical device
11	21 not allowed in direct mode
12	22 assign to standard files is not allowed
--	F3 Too many open files

Function INT24Result: Integer;
Var
  I: Integer;

```

```

Begin
  I:=IOResult;
  If INT24Err Then
    Begin
      I:=I+256* Succ(INT24ErrCode);
      INT24On;
    End;
  INT24Result:=I;
End;

```

(INT24Result returns all the regular Turbo IOResult codes if no critical error has occurred. If a critical error, then the following values are added to the error code from Turbo:

256:	Attempt to write on write protected disk	
512:	Unknown unit	[internal dos error]
768:	Drive not ready	[drive door open or bad drive]
1024:	Unknown command	[internal dos error]
1280:	Data error (CRC)	[bad sector or drive]
1536:	Bad request structure length	[internal dos error]
1792:	Seek error	[bad disk or drive]
2048:	Unknown media type	[bad disk or drive]
2304:	Sector not found	[bad disk or drive]
2560:	Printer out of paper	[anything that the printer might signal]
2816:	Write fault	[character device not ready]
3072:	Read fault	[character device not ready]
3328:	General failure	[several meanings]

If you need the IOResult part, use
 I:=INT24Result and 255; [masks out the INT 24h code]

For the INT 24h code, use
 I:=INT24Result Shr 8; [same as Div 256, except faster]

INT24Result clears both error codes, so you must assign it to a variable if you want to extract both codes:

```

J:=INT24Result;
WriteLn('Turbo IOResult = ',J And 255);
WriteLn('DOS INT 24h code = ',J Shr 8);

```

Note that in most cases, errors on character devices (LST and AUX) will not return an IOResult, only an INT 24h error code.)
