5TH WEATHER WING TECHNICAL NOTE

COMPUTING BASIC SOLAR AND LUNAR DATA FROM THE AIR ALMANAC

DTIC ELECTE JAN 1 1 1988 S D

December 1987

5WW/DNC

Abstract: This Technical Note provides programmed instruction on the us of the Air Almanac to compute times of sunrise, sunset, moonrise, moonset, and duration of civil twilight for any location between latitudes 60°S and 90°N. Appropriate basic astronomy is included. This Technical Note updates and supersedes 5WW/TN-79/002.

Original Authors-Capt John Sanders and T5gt Charles R. Elliott
Update by - MSgt George T. Gilligan Jr.

DD FORM 1473

COMPUTING BASIC LIGHT DATA FROM THE AIR ALMANAC

INTRODUCTION

A pilot comes into your weather office and asks for the time of sunset at his destination; or perhaps you're out in the field and have no access to a computer or some other means of computing astronomical data. How can you provide this information using the Air Almanac?

This Tech Note, which has been reviewed by the Nautical Almanac Office. U.S. Naval Observatory, describes the procedures for extracting these data from the Air Almanac. It will also describe basic theories and laws governing these phenomena. A frame-by-frame programmed learning approach is used.

The Air Almanac is published annually by the Naval Observatory, and is available from the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402. Note: AWS units should obtain the Almanac using procedures defined in AWSR 7-1.

The tables and graphs reproduced in this Tech Note are from the Air Almanac 1987 edition; consequently the data, table numbers and page numbers will not necessarily agree with another edition. The procedures for extracting the data are the same, regardless of the edition used.

To complete some of the calculations you will need a few sheets of scratch paper, both to cover the answers (which follow the questions) and to make calculations. A clear plastic straight edge, and in some cases either a pocket calculator or trigonometric tables will also be needed .

The following publications were used in preparing this Tech Note:
a. AFM 51-40, 1983, Air Navigation , Chaps 9-10.
b. The Air Almanac, U. S. Naval Observatory, U. S. Government Printing Office, Washington D.C., 1987.

Upon completion of the Program you should be able to extract the data necessary to support your mission directly from the Air Almanac. You can use a worksheet similar to the one provided at the end of this text, to make the extraction of data easier. ED.Note: The worksheet was based on an idea of SMSgt Depew of 25 Wea Sq. He had developed a similar worksheet, which was distributed for use to his subordinate units.

LEARNING OBJECTIVES

1. State the main reason why sunrise, sunset and twilight times change from day-to-day.

2. Name two factors that cause moonrise/set times to change from day to day.

3. Given a date and a position between 72 Deg. N. and 60 Deg. S, obtain the times of sunrise/set, moonrise/set, and morning and evening civil twilights in either Universal Time (Greenwich Mean Time), Local Mean Time, Local Standard and/or Daylight Savings Time, by using the tables in the Air Almanac.

4. Given a date and a position between 65 Deg. N. and 90 Deg. N, obtain the times of sunrise/set, moonrise/set, and morning and evening civil twilights in either Universal Time (Greenwich Mean Time), Local Mean Time, Local Standard and/or Daylight Savings Time, by using the tables in the Air Almanac.

5. Given a location, date and time, calculate the azimuth and altitude of the sun.

PROGRAMMED LEARNING TEXT

FRAME 1

In order to utilize the Air Almanac to find Sunrise/set, and twilight times for your given location you should have some background as to why these times vary both on a daily basis and also latitudinally. The main reason the sun does not rise at the same time every day is the fact that the earth's axis is tilted with respect to it's orbital plane. There are other factors such as, the earth's elliptical orbit and it's wobble at the, poles but this only contributes a few minutes to the annual variation. However, it is the tilt of the axis that causes the seasons and the extremes in the lengths of daylight and darkness.

In the illustration of the earth and its orbit (Figure 1), the 21 December (winter solstice) and 21 June (summer solstice) earth representations have been enlarged to show the extremes in length of daylight caused by first one pole, then the other being tilted toward the sun. Notice in the enlargements that the length of daylight varies with latitude. On 21 June, for example, the length of daylight becomes progressively shorter as you move from north to south.

The axis remains tilted in the same direction as the earth moves in its orbit around the sun. This causes the length of daylight at any one location to vary from day to day. On 21 March (spring equinox) and 21 September (autumnal equinox), the axis' tilt is in a plane perpendicular to the sun's rays, and the durations of daylight and darkness are about 12 hours each for all latitudes.

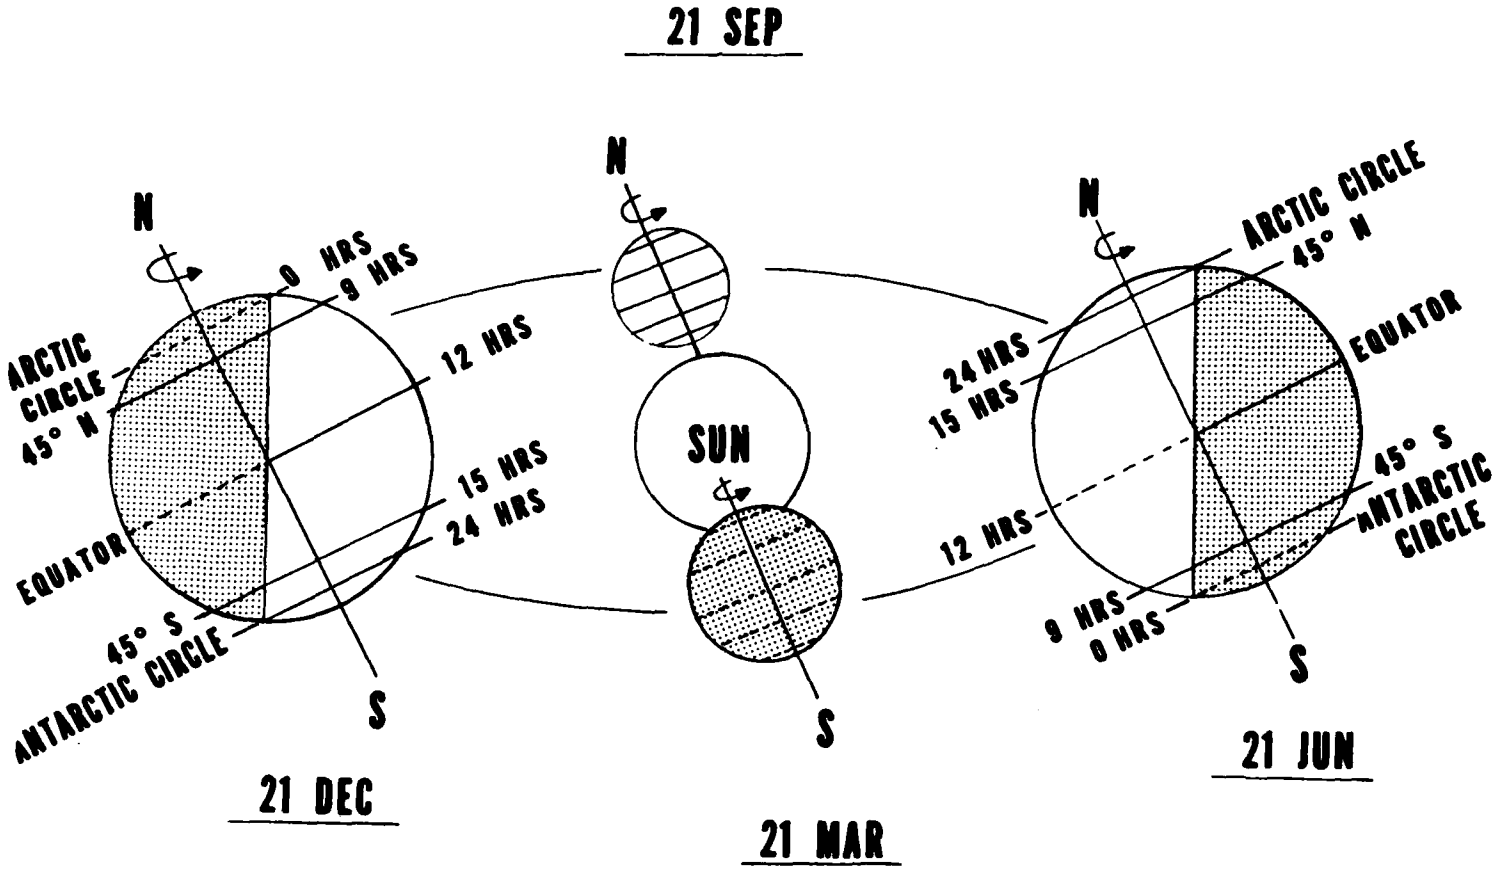

Figure 1. ILLUSTRATION OF EARTH'S ORBIT AND EFFECTS OF TILTED AXIS UPON LENGHT OF DAY (DATES VARY SLIGHTLY FROM YEAR TO YEAR).

Using the illustration, (Figure 1) state the approximate duration of daylight for the latitude 45° N. on the following dates:

A. 21 December _____

B. 21 March _____

C. 21 June _____

D. 21 September _____

****

ANSWER:

A. 9 hours

B. 12 hours

C. 15 hours

D. 12 hours

FRAME 2

The main reason that the times of sunrise/set, and the begin/end times of the twilights vary is because:

__ A. of the obliquity of the ecliptic

__ B. the poles wobble.

__ C. the earth's orbit is an ellipse.

__ D. the earth's axis is tilted 23 1/2° with respect to the plane of the earth's orbit.

****

ANSWER:

X D.

FRAME 3

The earth's axis tilt and other factors are taken into consideration by the Naval Observatory when they compute the times of sunrise/set and twilights, which are published in the Air Almanac. The published Almanac times are Greenwich Mean Time (GMT) or they are also called Universal Time (UT). "Mean time" is based on the assumption that the earth rotates about its axis at a constant velocity (actual changes from one day to the next are very slight) Because of this assumption, it's possible to establish the following relationship between time and the earth's rotation:

TIME	ARC
24 hours	360°
1 hour	15°
4 minutes	1°

Thus in two hours the sun will appear to pass through an arc of 30°. Greenwich Mean Time (GMT) is mean time measured with respect to the Greenwich Meridian (See Figure 2.) At 0000 GMT, the sun (to be correct we should say the "mean sun") is directly above the longitude opposite from Greenwich, i.e.; 180° from Greenwich, and at 1200 GMT the mean sun is directly above the Greenwich longitude. Local Mean Time is similar to GMT except it is measured with respect to your local position. At 0000 LMT the mean sun is directly above your longitude.

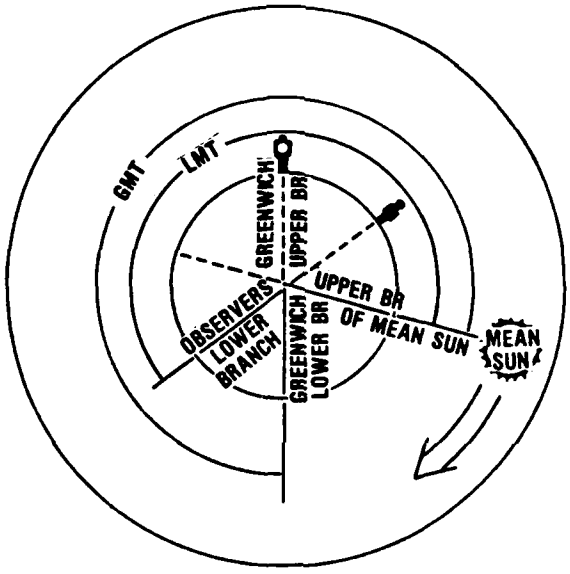

Figure 2. Measuring Greenwich Mean Time (GMT).

LMT is not useful to regulate our daily activities because it varies continuously with longitude since it is based on the position of the observer. LMT is useful in solar calculations because "for all places of the same latitude the corresponding phenomena will occur at approximately the same Local Mean Time (L.M.T.) and this will be approximately the same GMT. tabulated (Ed. Note. in the Air Almanac), since GMT. = L.M.T. at Greenwich. The disadvantage of using LMT to regulate our daily activities was overcome by the introduction of zone time. The world has been divided into 24 zones, each zone being 15° (or one hour) wide. Each zone uses the LMT of its central meridian as the standard time (local standard time (LST)) for the zone.

Below is a a replica of the list of contents (Figure 3) taken from an Air Almanac. The tables and graphs used in this programmed text have been underlined.

LIST OF CONTENTS

Figure 3. Air Almanac List of Contents

NO RESPONSE NECESSARY

FRAME 4

In the sunrise/set, and twilight tables the times are listed in Local Mean Time (LMT) for every third day for the specific latitudes shown at the side of the table. When there is less than a three minute change between the days listed, simply use the time listed for the nearest date. If the change is three minutes or more, you must interpolate for the date required. You must also interpolate between latitudes, if your latitude of interest is not listed.

Using the sample sunrise table in Figure 4, find the times (LMT) of sunrise for the following dates and latitudes:

A. 3 December, 50° N. _____

B. 13 December, 20° S. _____

C. 29 November, 59° N. _____

D. 1 December, 23° N. _____

The above table is for converting expressions in arc to their equivalent in time; its main use in this Almanac is for the conversion of longitude for application to L.M.T. (*added* if *west*, *subtracted* if *east*) to give G.M.T., or vice versa, particularly in the case of sunrise, sunset, etc.

Figure 5. Conversion of Arc To Time Table

FRAME 5

The sunset, and the morning and evening civil twilight tables are read just like the sunrise table. Remember, these times are the Local Mean Time (LMT) for the event, and can be converted to either Local Standard Time or Universal Time (GMT) by using the Conversion of Arc to Time table (Figure 5) of the Almanac. Notice that the conversion factor in the Arc to Time Table is simply 1° of longitude equals 4 minutes time. The first six columns of the table are the hours and minutes conversion, while the last column is the minutes and seconds conversion. For example, (using Figure 5) we will find the time difference corresponding to a longitude difference of 147° 37'. located 147° in the third column. you will find that 147° equals 9 hr 48 min and the 37' = 2 min 28 sec. add them together:

$$\begin{array}{r} 9 \text{ hr } 48 \text{ min} \\ + \quad 2 \text{ min } 28 \text{ sec} \\ \hline 9 \text{ hr } 50 \text{ min } 28 \text{ sec} \end{array}$$

In computing these times, you can round off to the nearest minute. thus, the time difference corresponding to a longitude difference of 147° 37' is 9 hr. 50 min.

Find the time difference corresponding to the following longitude differences. Round off the time to the nearest minute.

A. 76° 17' _____

B. 14° 55' _____

C. 122° 39' _____

D. 120° 16' _____

****

ANSWER:

A. 5 hr 05 min

B. 1 hr 00 min

C. 8 hr 11 min

D. 8 hr 01 min

FRAME 6

Using the Conversion of Arc To Time Table to convert LMT to GMT is fairly simple, since you are simply converting from your longitude position to the 0° Meridian. First, convert your longitude to time; then, add this conversion to LMT if your longitude is west, or subtract it from LMT if your longitude is east.

For example, here is the conversion of 0630 LMT to GMT for Langley AFB, Va, which is located at 76° 21' W.

```
 76°     = 5 hr 04 min
+ 21'=       01 min 24 sec
-------------------------
      5 hr 05 min 24 sec  = 5 hr 05min

      6 hr 30 min LMT
    + 5 hr 05 min (added; longitude is west)
    -----------------
     11 hr 35 min = 1135 GMT
```

Convert 0630 LMT on 18 May to GMT for the following stations:

A. Fulda, Germany 9° 41' E. _____

B. Osan, Korea 127° 02' E. _____

C. Brasilia, Brazil 47° 56' W. _____

D. Amberley, Australia 152° 43' E. _____

****

ANSWER:

A. 0552 GMT, 18 May

B. 2202 GMT, 17 May

C. 0942 GMT, 18 May

D. 2019 GMT, 17 May

Frame 7

The easiest way to find LST using strictly the Air Almanac and nothing else is to simply find GMT, as you did in Frame 6, and apply the correction to standard time which is indicated in pages A20-A23 of the Air Almanac. NOTE: Standard Time corrections are also located in the Flight Information Publication (FLIP) pertaining to your Area of interest. The Standard Time zones are based on specific Standard Meridians which are normally spaced at 15° of longitude, either east or west, beginning with the Prime Meridian (0°); however, either geographical considerations or local law can be used to adjust Standard Time. Because the LST for your location must be figured using The Standard Meridian for your time zone, which is not necessarily the one closest to it, you must insure that the proper correction is applied. e.g. In eastern and western Kentucky there are 2 different time zones; Newfoundland has a Standard Time correction of +3 hrs 30 Minutes etc.

If you *do know* the Standard Meridian that is used for your time zone then you simply apply the correction as determined from the Arc to Time Table to the Local Mean Time listed in the Sunrise/set tables. Add the correction if you are west of the Standard Meridian and subtract the correction if you are east. This correction will normally be less than 1 hour, remember, because Standard Meridians are normally 15° apart, and 1° of longitude = 4 minutes time. (See the map on page 49)

Let's use Langley AFB, VA as an example of this last case. Langley, which is located at 37° 05' N., 76° 21' W. is in the Eastern Standard Time Zone which uses 75° West longitude as it's Standard Meridian. The LMT for sunrise on the 18th of March is 0608 LMT. What time does sunrise (LST) occur at Langley? Langley AFB, VA is located 1° 21' West of the Standard Meridian and this equates to a correction of 5 minutes (1° 21' = 5 min 24 sec which rounds off to 5 min). The correction added to the published LMT, indicates a sunrise time at Langley AFB on 18 March of 0613 LST.

Find time of sunrise (LST) for the following stations using a time of 0630 LMT:

	Standard Meridian	
A. Fulda, Germany (9° 41' E.)	15° E.	_____
B. Osan, Korea (127° 02' E.)	135° E.	_____
C. Brasilia, Brazil (47° 56' W.)	45° W.	_____
D. Amberley, Australia (152° 43' E.)	150° E.	_____

****

ANSWER:

A. 0651 LST

B. 0702 LST

C. 0642 LST

D. 0619 LST

FRAME 8

Some locations use Daylight Savings Time (LDT). For an indication of which countries use LDT see the Standard Time tables pp. A20-23 or the applicable Flight information Publication for your area of interest. To convert to Daylight Savings Time (LDT) you just add 1 hour to the LST.

Using the following Figure (Figure 6) and the Conversion of Arc to Time Table (Figure 5), find the LDT of sunset on 11 September for the following stations:

		Standard Meridian	
A. Fulda, FRG.	(50° 33' N. 9° 41' E.)	15° E.	_____
B. Langley AFB, Va	(37° 05' N. 76° 21' W.)	75° W.	_____
C. Brasilia, Bra.	(15° 51' S. 47° 56' W.)	45° W.	_____
D. Amberley, Aus.	(27° 39' S. 152° 43' E.)	150° E.	_____

Figure 6. Sunset Table.

ANSWER:

A. 1946 LDT

B. 1920 LDT

C. 1807 LST — Why not LDT? Because it's not summer in the

D. 1740 LST — southern hemisphere! Gotcha!!!!

PROGRESS CHECK

FRAME 9:

Using the extracts from the four sun-event tables provided below and the Conversion of Arc to Time table in figure 5, find the Local Standard Times for the start of morning civil twilight, sunrise, sunset, and the end of civil twilight on 1 January for the following stations:

A. Langley AFB, Va (37° 05' N. 76° 21' W.)

B. Amberley, Aus. (27° 39' S. 152° 43' E.)

Figure 7. Sun Events Tables

ANSWER:

A. 0650,0719,1659,1728

B. 0430,0457,1849,1915

(Answers within one minute of these can be considered correct because of the interpolation involved.)

ONE FINAL NOTE: Nautical and Astronomical Twilight times are not provided in the Air Almanac, but can be estimated by using the time difference between sunrise and start of civil twilight, or sunset and end of civil twilight. Add the difference to end of Civil Twilight to get the end of nautical twilight; add the difference again to get end of astronomical twilight. For corresponding start of twilight times, subtract the difference from starts of civil twilight etc.

So far, you have learned how to find times of sunrise/set, and the twilights between the latitudes of 72° North and 60° South. Although the Air Almanac does not cover the area south of 60° South latitude, it does cover the area north of 72° North. The next few frames will explain these graphs.

NO RESPONSE NECESSARY

FRAME 10:

An example of a Semiduration of Sunlight Graph is shown below.

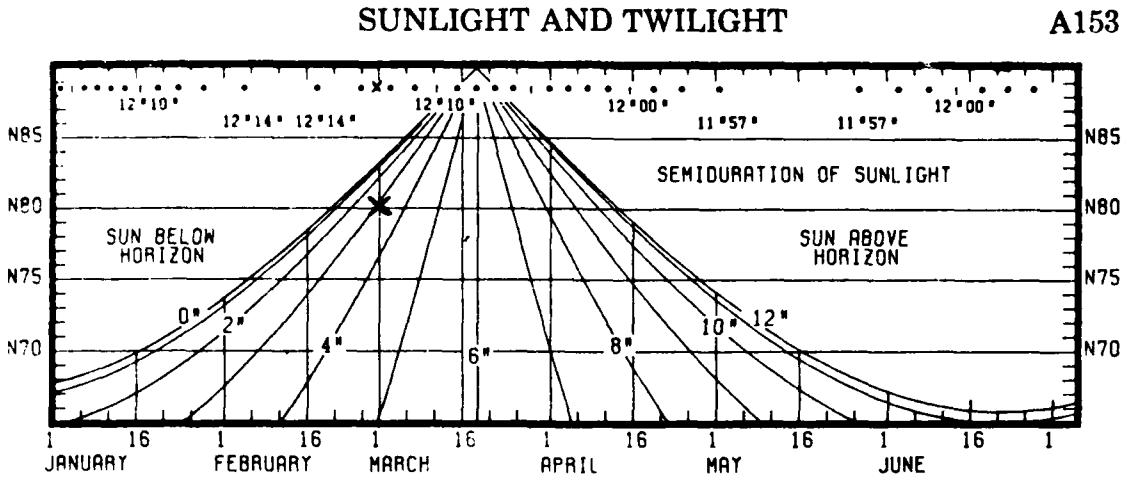

Figure 8. Semiduration of Sunlight

The graph covers a six-month period; the months are indicated across the bottom. Every fifth day there are tick marks; they are depicted along the top and bottom of each chart. The sides of the graph indicate latitudes from 65° North to 90° North. Across the top you also see time in hours and minutes. e.g. 12H 14m ....etc. These times are the times of meridian passage which can be read to the nearest minute for each day. Meridian passage is the time that the sun passes your longitude; i.e. the time of apparent noon during each 24-hour period. The skewed lines on the graph are the semiduration lines. They show the number of hours of sunlight that will occur before and after the meridian passage--hence the term "semiduration". "Sun below horizon" and "Sun above horizon" are self-explanatory. In the regions of the graph that you find difficult to interpret, the phenomena themselves are generally speaking, uncertain.

FRAME 10 (contd)

Here's an example of how to read the graph to find the sunrise/set times on 1 March at 80° North (using figure 8): first, follow the "1 March" line to the top of meridian passage. An "x" has been placed there, between 12h 14m and 12h 10 m, or approximately 12h 12m. Thus, the meridian passage time on 1 March for any meridian is 12h 12m LMT. Next proceed along the line to your latitude of interest (80° N.). An "x" has also been placed at that point. This point lies approximately on the skewed line labelled "3h." Therefore, the semiduration of sunlight on 1 March at 80° North latitude is 3 hours. With 3 hours sunlight before and after the meridian passage time you can now compute the sunrise to be 0912 LMT (12 - 3h = 0912) and the sunset to be 1512 LMT (12h 12m + 3h = 1512) Now it's your turn! Use figure 8 and find local mean times of sunrise/set for the following dates and latitudes. (A clear straight edge will be useful here.)

		Sunrise	Sunset
A. 16 April,	80° N.	_____	_____
B. 10 February,	70° N.	_____	_____
C. 15 March,	78° N.	_____	_____
D. 1 April,	73° N.	_____	_____

****

ANSWER:

A. Sun continuously above horizon.

B. 0854 LMT 1534 LMT

C. 0639 LMT 1739 LMT

D. 0449 LMT 1919 LMT

FRAME 11

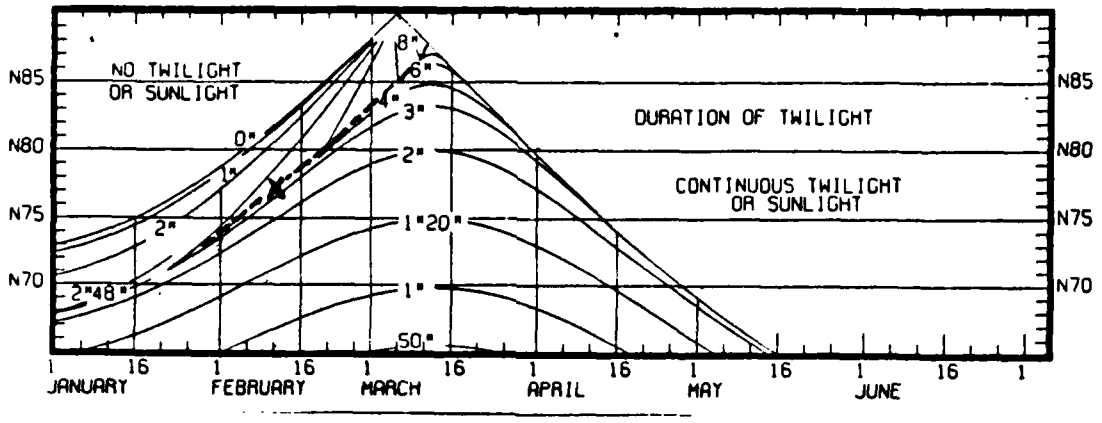

Figure 9. Duration of Twilight Graph

The Duration of Twilight graph (Figure 9) is similar to the Semiduration of Sunlight graph; but notice that the skewed hour lines are not smoothly curved as they are on the sunlight graph. They are kinked in places. These kinks, if superimposed onto the corresponding sunlight graph, would fall on the "0h" line, and along this line the sunrise may or may not occur. We have drawn a dashed line in the example which enables us to define the four areas in the chart as follows:

Area A - No Twilight or sunlight. In this area the sun never gets within 6° of the horizon.

Area B - This is the area where the sun is continuously below the horizon but does get near enough (within 6°) to the horizon during a portion of the day that there is twilight. The value determined in this region of the graph is actually the interval between the beginning of twilight and the time of meridian passage.

Area C - This value when applied to the time of sunrise (-) or sunset (+) gives you the amount of available twilight

Area D - Continuous Twilight or Sunlight - self-explanatory.

FRAME 11 (contd)

Let's work an example to show just how this graph works (see figure 8) on a worst case scenario. We want to find out the amount of twilight available on 11 February at 77° North (Point "x"). As you can see it sits in the heart of the transition zone between sunrise and no sunrise. The first thing we do is draw a dotted line connecting the kinks in the hour lines. Point "x" is located between the "3h" lines, so we must interpolate between the 3h and 4h lines to get a usable value to work with. It is located about 2/3 of the way (2/3 of 60 min = 40 minutes), so the correct value of twilight is 3h 40 min. The sun may or may not rise completely above the horizon on this date at this position. A good light forecast for this date would be 7 hrs 20 minutes of twilight, with the possibility of the sun actually being visible for a few minutes around the time of meridian passage.

Now, you work a few examples. Find the total duration of twilight (using figure 9) for the following dates:

A. 16 January, 78° N. _____

B. 1 February, 73° N. _____

C. 31 March , 80° N. _____

D. 16 February, 80° N. _____

ANSWER:

A. No Twilight or sunlight.

B. 6 hr 00 min.

C. Continuous twilight or sunlight.

D. 6 hr 40 min.

FRAME 12

The Duration of Twilight (Figure 11) graph is read in conjunction with the Semiduration of Sunlight graph (Figure 10). Notice that the twilight graph does not have the times for meridian passage on it. However, since the twilight graph is always placed directly underneath the sunlight graph in the Air Almanac, the meridian passage time can be obtained with a straightedge, if necessary.

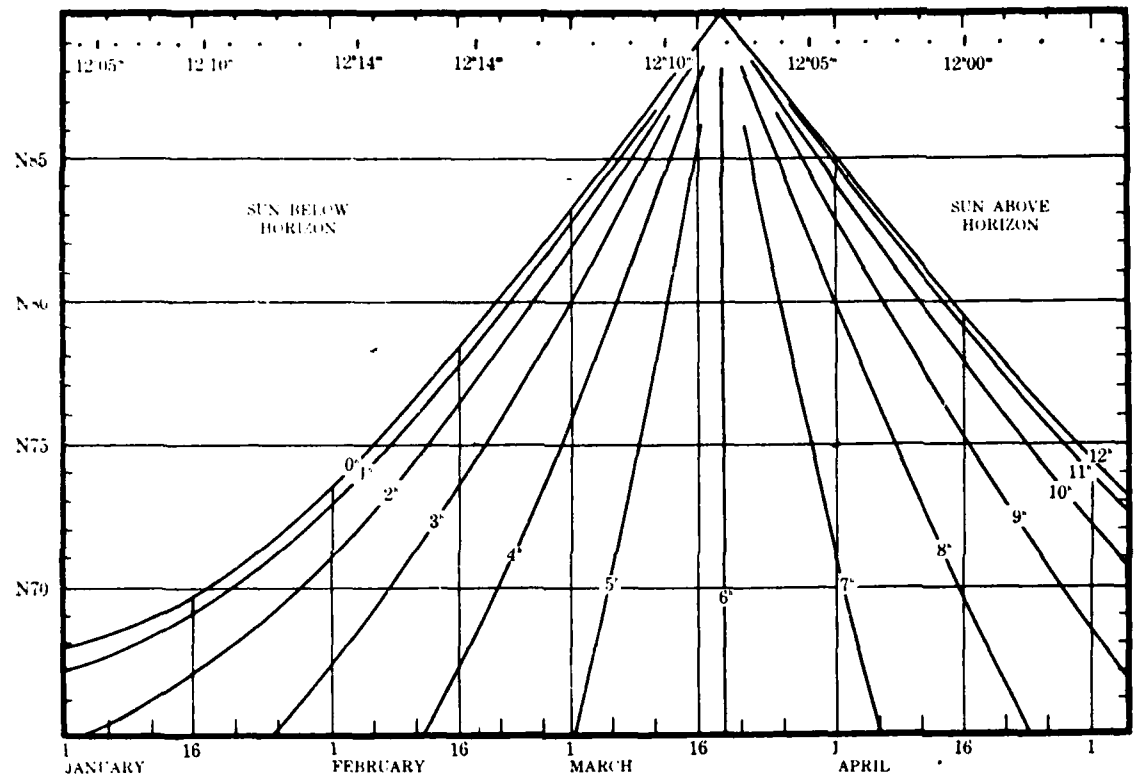

Figure 10. Semiduration of Sunlight

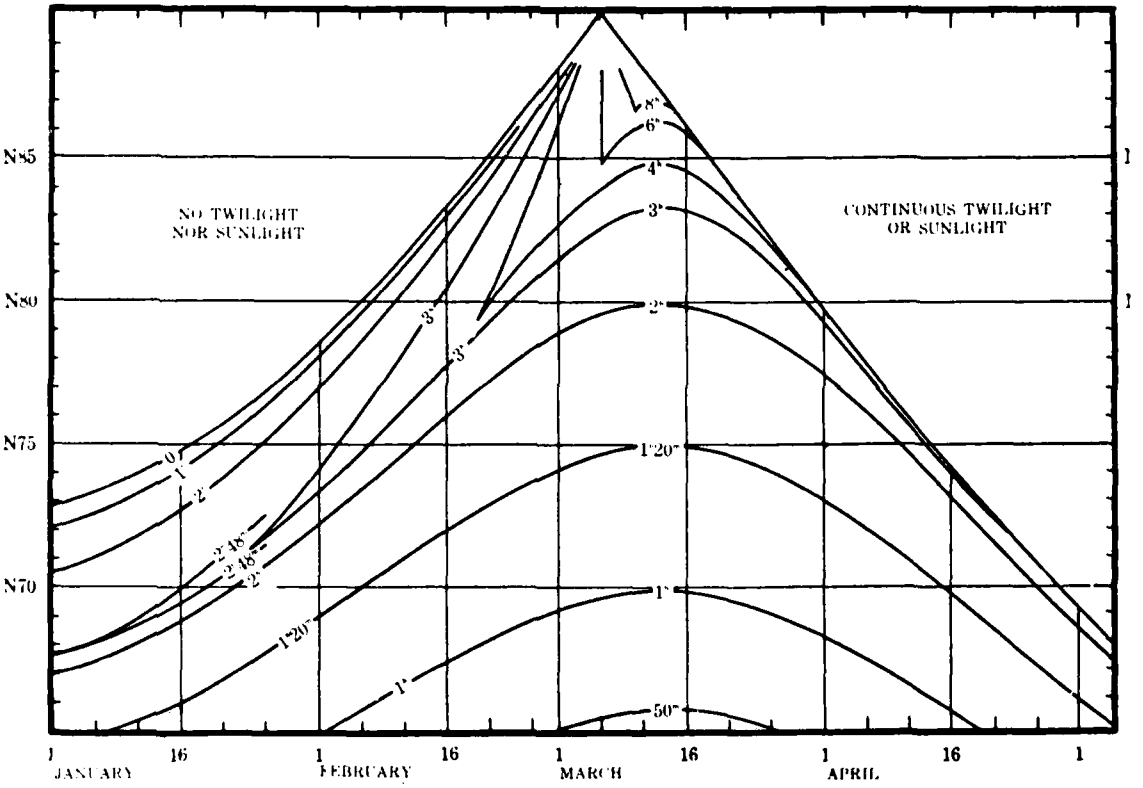

Figure 11. Duration of Twilight

FRAME 12 (contd)

Let's recap the steps for finding the times of sunrise/set, and twilight times in the 65° to 90° North latitude region.

1. Find the time of meridian passage.
2. Find the Semiduration of Sunlight.
3. Apply the value to the meridian passage time for sunrise (subtract) and sunset (add).
4. Find the duration of twilight.
5. Apply the value to the sunrise time (subtract) for begin time of morning twilight and to the sunset (add) to obtain the end of evening twilight.
6. Remember, even if there is no sunrise or sunset there can still be twilight. Subtract the value from the meridian passage time for beginning time; add the value to the meridian time to compute the end time of twilight.

Now let's find the local mean times (using Figures 9 and 10) for all of the events listed below:

	BEGIN TWI	SUNRISE	SUNSET	END TWI
A. 18 February, 75° N.	_____	_____	_____	_____
B. 16 April , 78° N.	_____	_____	_____	_____
C. 1 March , 84° N.	_____	_____	_____	_____
D. 1 April , 75° N.	_____	_____	_____	_____

ANSWER:

A. 0744, 0924, 1504, 1644
B. Continuous, 0200, 2200, Continuous
C. 0722, None, None, 1702
D. 0304, 0444, 1924, 2104

(Twilight times within 15 minutes of our answers may be considered as correct)

FRAME 13

To compute the sun's azimuth and elevation at a specific time and place, you must use the daily pages and Interpolation of GHA Table in the Air Almanac.

You will need a hand-held calculator; there are numerous programs available for both the TI-59, and HP 41 calculators. Programs are also being developed for microcomputers. See AWS TC 8X/001 for a listing of available programs. They are simple to use; just fill in the values from the Air Almanac, as directed.

NOTE: The time of sunrise/set is given as the time the observer on earth would first see the upper edge of the sun along the horizon. However, solar altitude is determined by the position of the sun's center not it's edge. Consequently, the time that the solar altitude equals 0° may not exactly match the time of sunrise/set.

NO RESPONSE NECESSARY

FRAME 14

You should now be able to calculate sunrise/set, and twilight times for any point North of 60° S. The next few frames will teach you how to find moonrise and moonset times for the same area. Their organization in the Air Almanac is the same as for sun times; there are tables for latitudes between 72° N. and 60° S., and graphs for latitudes between 65° and 90° N. Before discussing how to read these tables and graphs, let's look at some of the reasons that make them necessary.

NO RESPONSE NECESSARY

FRAME 15

The moon revolves around the earth once every 28 days or so. The phases of the moon are caused by its position in its orbit. Using figure 12 you can see how the moon is viewed from earth, by looking at the outer figures at each position. From space the moon can be

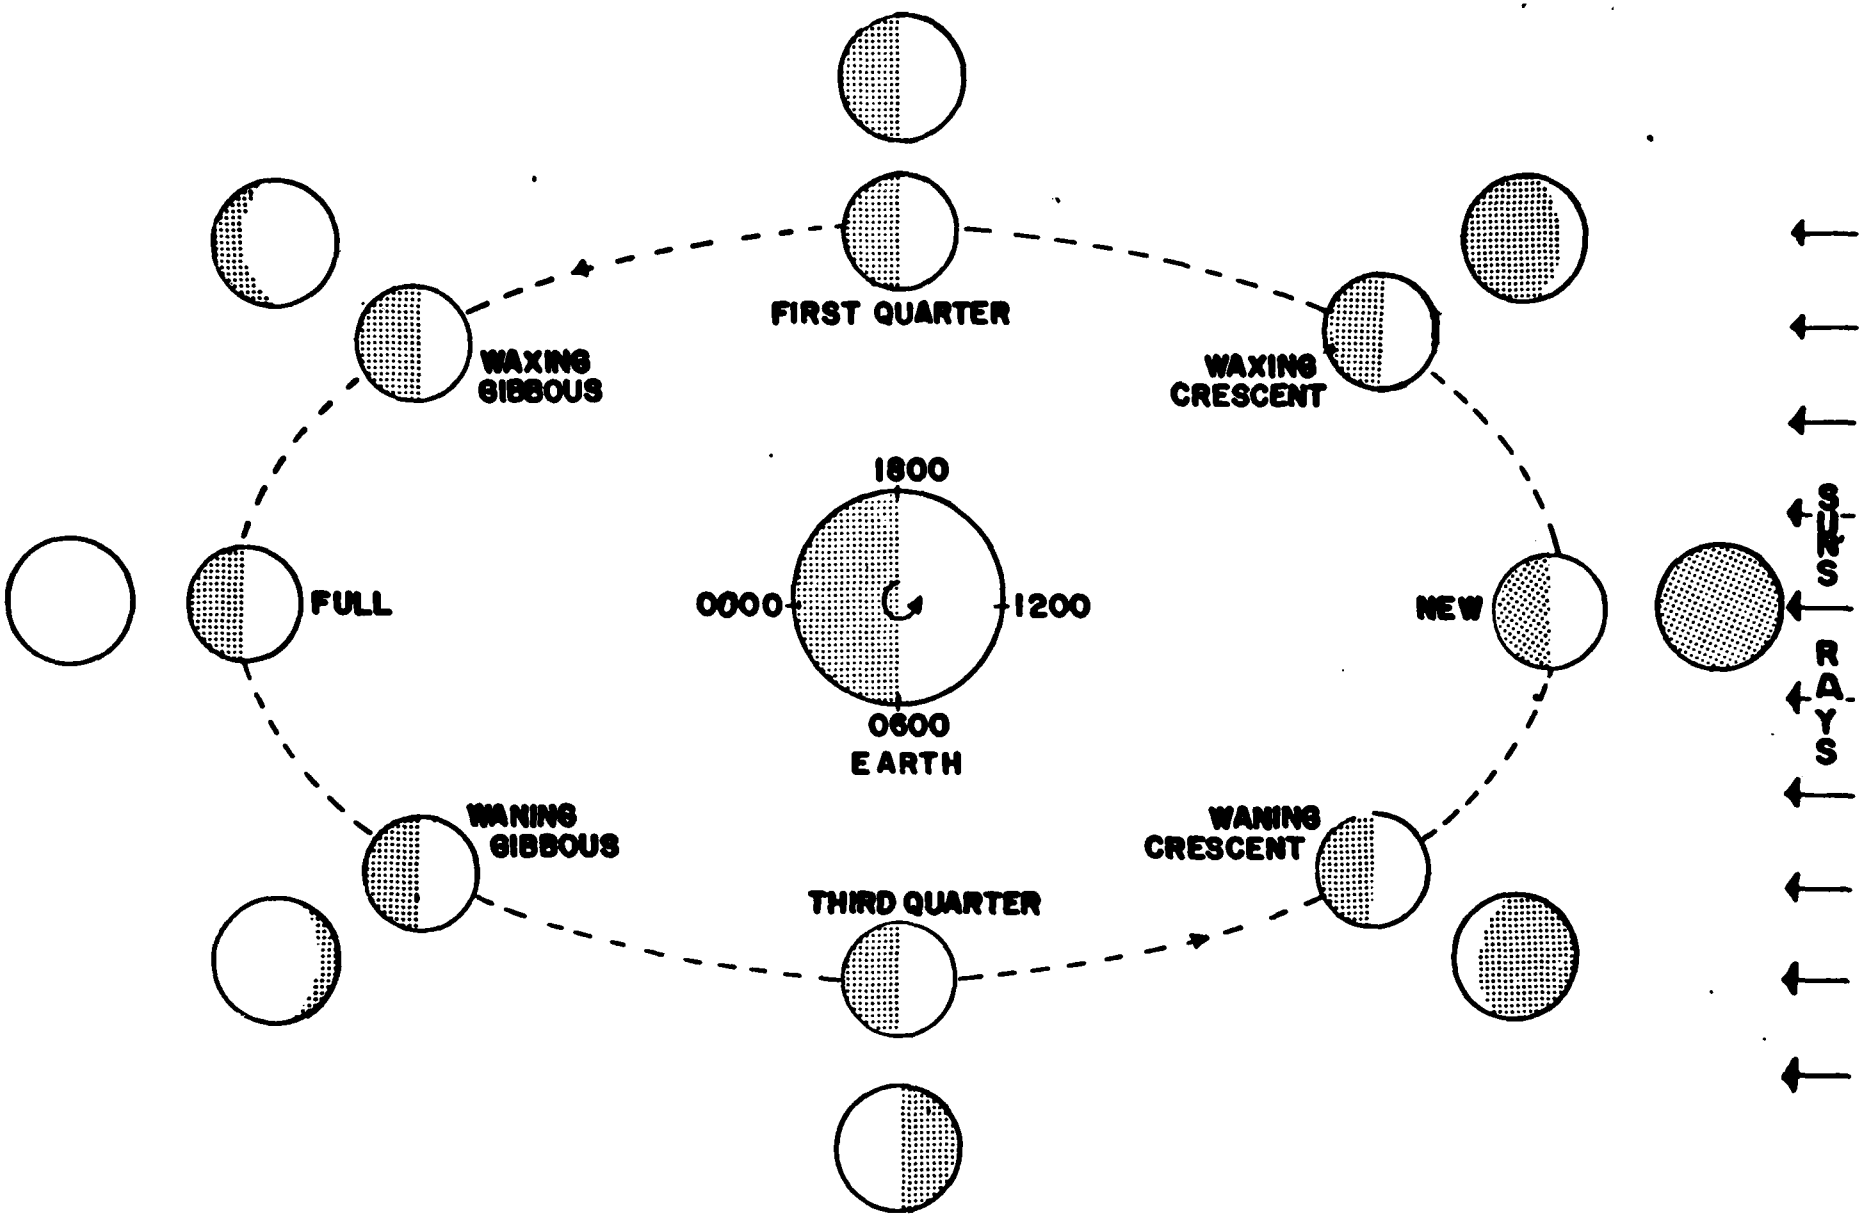

Figure 12. ILLUSTRATION OF LUNAR ORBIT AND PHASES

FRAME 15 (contd)

seen as half-illuminated at all times (the inner figures).

The 24 hour clock face around the earth illustrates to you how you can obtain a rough estimate of the times of moonrise and moonset by the phase of the moon. Look at the full moon portion of the diagram, which is adjacent to 0000 time on the clock face. The full moon crosses the meridian around midnight. Imagine that you are at a point on the right edge of the clock-face earth. As this point turns counter-clockwise (direction of the arrow), the full moon becomes visible as you approach the 1800 position. Moonrise occurs at about 1800 for a full moon. Continuing around the clock face, the moon would recede from your view at about 0600. Moonset occurs around 0600 for a full moon.

In other words, the moon is 'full' because it is located on the side of the earth opposite the sun. We tell time on earth by our position in the daily rotation of the earth with respect to the sun. A full moon can only be seen from earth from about 1800 to 0600 because of the mechanics of the situation.

EXCEPTION: In extremely high latitudes, the mechanics get more complicated due to the axis tilt and other irregularities that will be dealt with in succeeding frames.

The other phases of the moon are only visible between certain hours for the same reasons.

Using Figure 12, state the approximate times of moonrise and moonset for:

	MOONRISE	MOONSET
A. Third Quarter Moon	_____	_____
B. Full Moon	_____	_____
C. First Quarter Moon	_____	_____

****

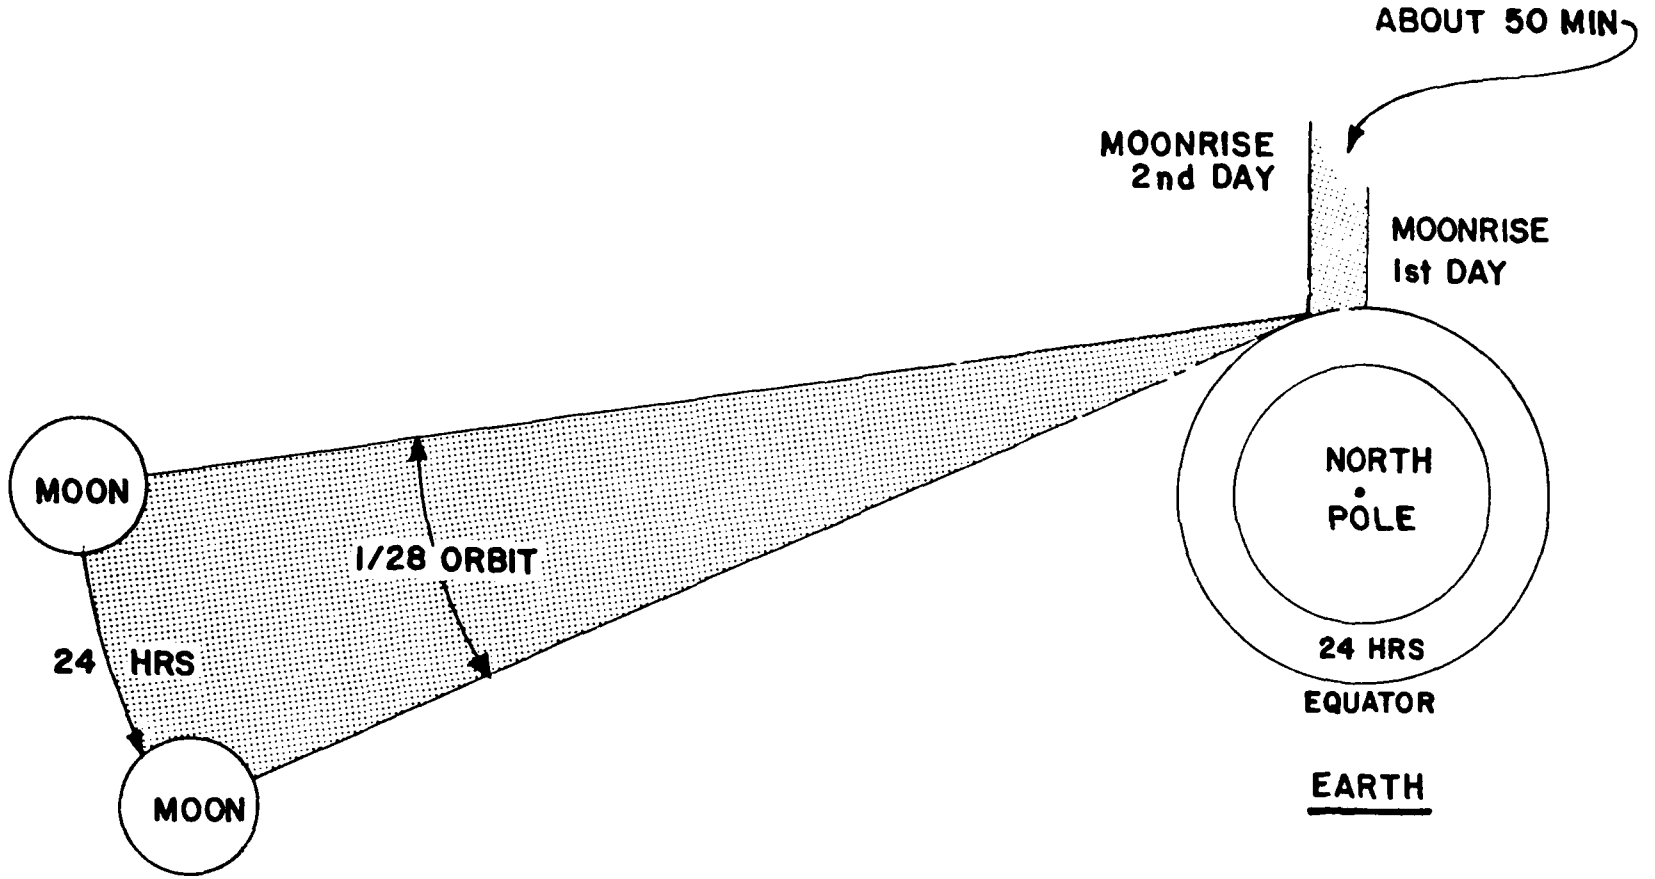

Figure 13. ILLUSTRATION OF HOW CONSTANT ORBITAL SPEED AND ZERO ORBITAL ANGLE WOULD AFFECT MOONRISE TIMES

ANSWER:

A. 0000 1200

B 1800 0600

C. 1200 0000

FRAME 16

Two factors cause moonrise and moonset times to change from day to day. They are the moon's orbital speed and its orbital angle. Let's see if we can explain that more fully. Assume that both the moon's orbital speed and angle are constant. This would result from the idealized situation of the moon being in a circular orbit directly above the equator. The moon orbits the earth once every 28 days; this equates to 1/28 of its orbit being completed every 24 hours. 1/28 of 24 hours equals approximately 51 minutes. Now, with the moon making a circular orbit in the same direction that the earth turns this would mean that the moonrise/set would occur about 51 minutes later each day (See Figure 13).

The exaggerated illustration in Figure 12 looks down on the earth at the North Pole with the equator the edge of the circle. The earth is rotating clockwise and the moon is orbiting in the same direction. Therefore, each day (24 hours) when a standard meridian on earth makes a complete revolution, it must continue on for 51 more minutes for the moon to come in view. Consequently, moonrise occurs 51 minutes later each day.

Because of it's orbital speed, the moon would rise about 51 minutes later each day if the moon's orbit was:

A. Elliptical and inclined to the equator.

B. Circular, and directly above the equator.

****

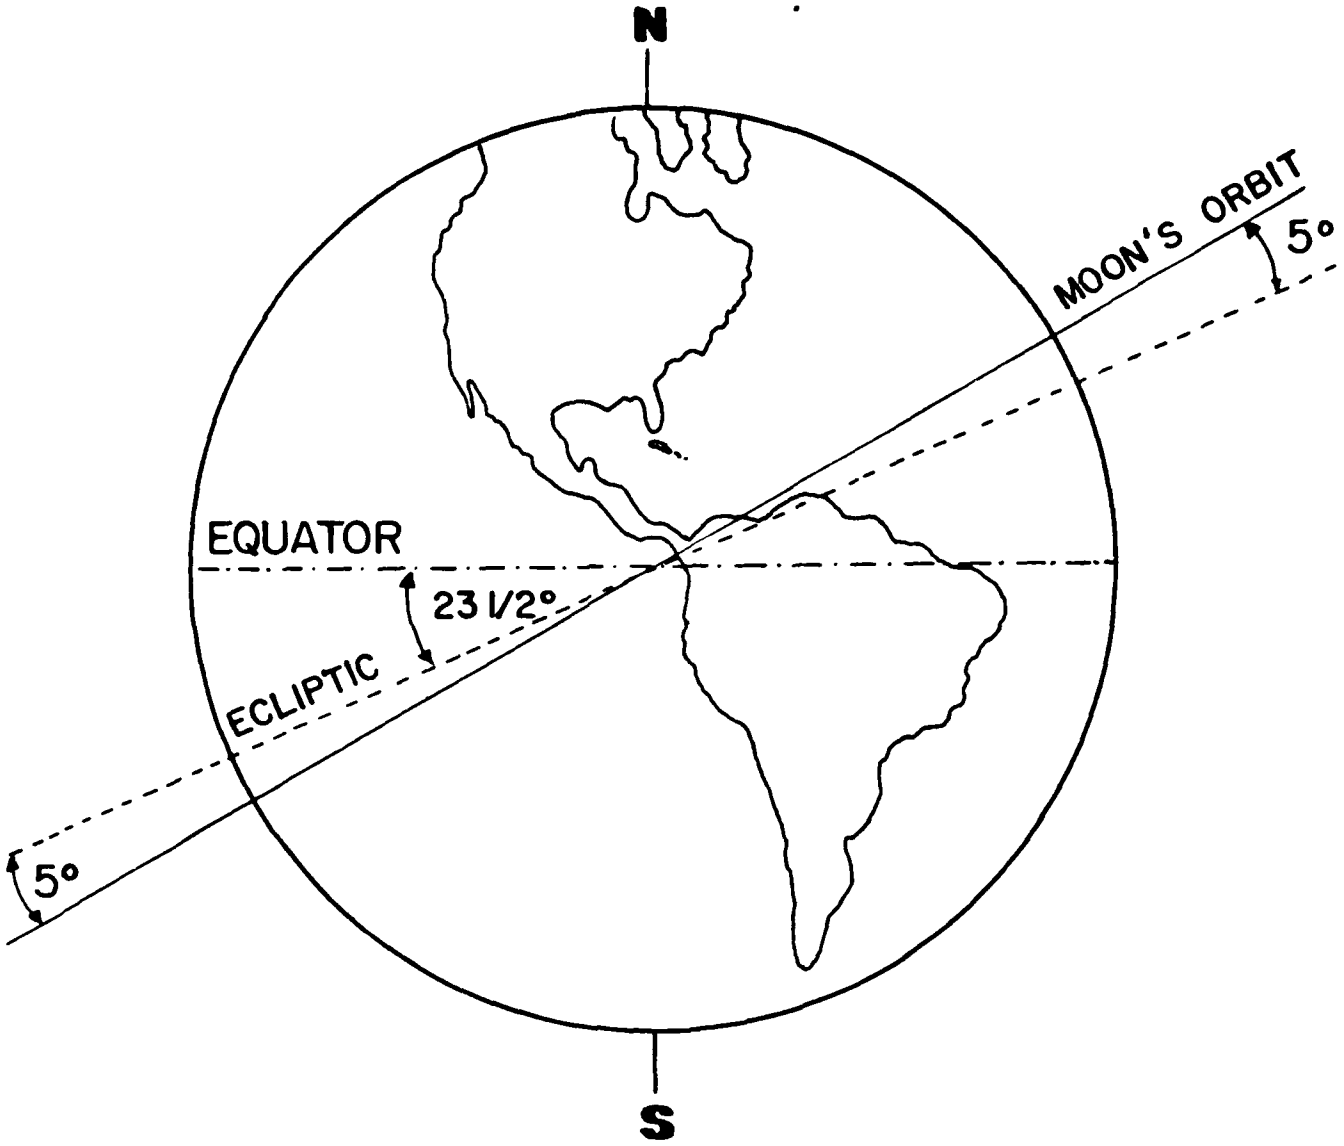

Figure 14. ECLIPTIC AND ORBITAL PATH OF MOON RELATIVE TO EQUATORIAL PLANE OF EARTH

ANSWER:

A. Circular and directly above the equator.

FRAME 17

With the moon in a circular orbit above the equator, moonrise would occur about 51 minutes later each day for all positions on the earth (except the poles). However, the moon is, in fact, neither in a circular orbit, nor does it orbit directly over the equator. What does this mean? Well, for any one position in the low and mid latitudes the moon does rise about 51 minutes later each day, but the difference along a single meridian longitude can vary more than 6 hours between 60° S. and 72° N. This is mainly because of the moon's orbital angle. Rather than orbitting directly above the, equator the moon moves both north and south of the equator during each orbit. When the moon is in the northern part of its orbit, it can be seen earlier by northern observers than by those to the south, and vice versa.

Earlier, you learned that the sun moves 23 1/2° north and south of the equator during the course of a year because of the earth's axis tilt. The apparent path of the sun across the sky is called the ecliptic. The ecliptic crosses the equator at an angle of 23 1/2°. The moon's path crosses the ecliptic at an angle of 5°. The point where they intersect moves around the ecliptic in a little more than 18 years, causing the angle at which the moon crosses the equator to vary between 18 1/2° and 28 1/2°. These apparent paths are illustrated in Figure 14.

Moonrise varies by latitude along a particular meridian of longitude mainly because of the moon's:

A. orbital speed.

B. orbital angle.

C. elliptical orbit

D. circular orbit.

****

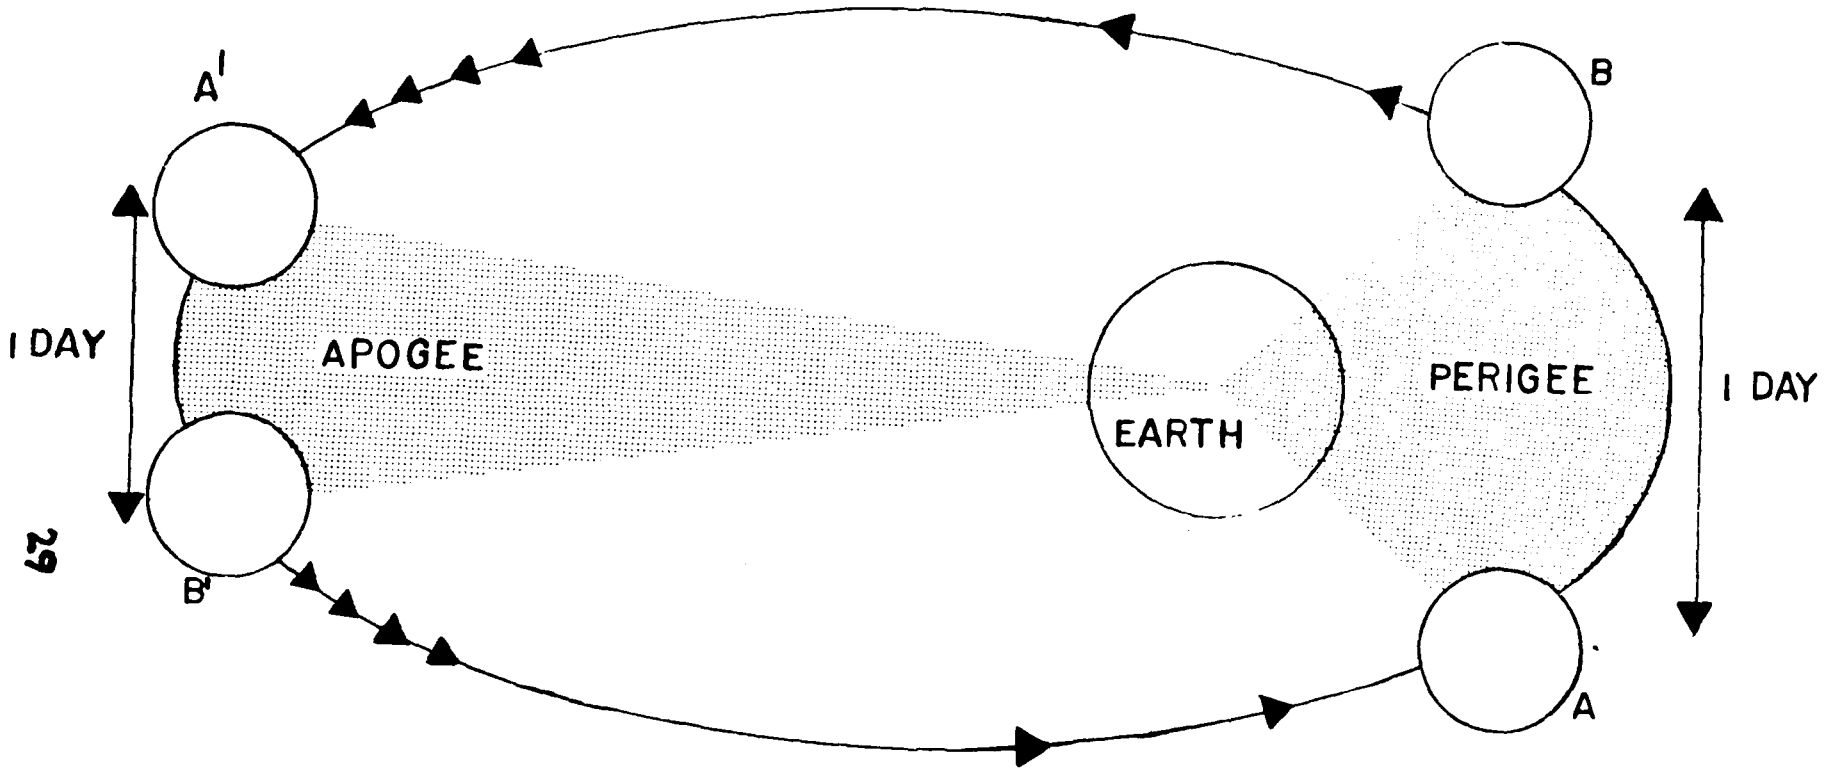

FIGURE 15. ILLUSTRATION OF NON-UNIFORM ORBITAL SPEED OF MOON

[illegible]

ANSWER:

[illegible]

[illegible] circular, it is elliptical. This [illegible] at times (perigee) and farther away [illegible] Law of Equal Areas, which is [illegible] faster in its orbit when it [illegible] when it is farther away. This much [illegible] the moon's non-uniform orbital speed [illegible] elliptical orbit. The distance from A to B represents [illegible] from A' to B' represents one day at Apogee.

Kepler's Law states that equal orbital areas are swept out in equal amounts of time. In other words, the two triangles have equal areas but are of different shapes. The moon is moving faster from A to B than from A' to B'. Moonrise at B would be more than 50 minutes later than at A, because the earth would have to turn farther. Conversely moonrise at B' would occur less then 50 minutes later than at A', because the earth would not have to turn so far.

The moon's elliptical orbit causes it's orbital speed to be:

A. Faster at perigee than at apogee.

B. Slower at perigee than at apogee.

****

ANSWER:

A. Faster.

FRAME [illegible]

[illegible] from day to day mainly because of the [illegible] orbital ____________.

****

ANSWER:

Speed; Angle (either order)

FRAME 19

The last few frames have shown that, although you can get a rough idea of moonrise/set times by the phases of the moon, specific times can only be obtained by considerations and calculations of data which include the moon's orbital speed and orbital angle. Next we will cover calculating the moonrise set data from the Air Almanac. If certain [illegible] this data from the Almanac seems a little complicated, you should now have some appreciation for the calculations involved. NOTE: Although it requires no calculation, Fractional Illumination data is provided in the Air Almanac. See the index for the exact page number.

****NO RESPONSE NECESSARY****

FRAME 20

To find moonrise/set times between 60° S. and 72° N. from the Air Almanac, you must use three different sets of tables. They are:

a. Moonrise, Moonset data (Daily Pages).

b. Interpolation of Moonrise, Moonset for Longitude.

c. Conversion of Arc to Time Table.

The moonset and moonrise tables are found in the upper right hand corner of each daily page. They alternate, with moonset on the left page and moonrise on the right page of each opening. The next two pages (Figures 16 and 17) are excerpts of complete daily pages with the moonrise and moonset tables circled.

NO RESPONSE NECESSARY

Sun SD 16.2

Moon SD 16′

Age 0d

Figure 17 SAMPLE TABLE

FRAME 14

Figure 13 contains moonrise and moonset tables which were taken from the daily pages. The first column of each shows the same latitudes as the sun tables. The second column gives the times of moonrise and moonset in LMT on the 180° meridian for those latitudes. Notice that there is more than six hours difference between the northernmost and southernmost times listed. This is because of the moon's orbital angle.

Because of the variability of the moon's orbital speed, there is a column to account for this difference labelled "Diff." Diff. is the half-daily difference (minutes) in local mean time for the phenomena. In simpler terms, this correction when applied to the published moonrise or set values will give you the LMT time that these events will occur at 180° longitude. NOTE: An Asterisk (*) is entered in the Diff. Column under extreme conditions where an interpolation cannot be made.

Figure 13. [illegible] MOONRISE/SET TABLES

FRAME 21 (cont)

From the moonrise table (figure 18), list the LMT of moonrise at 0° and 180° longitude for the following latitudes:

	0°	180°
A. 70° N.	____	____
B. 52° S.	____	____
C. 30° N.	____	____
D. 39° N.	____	____

****

ANSWER:

A. 1010, 1042

B. 0342, 0411

C. 0613, 0644

D. 0633, 0704

FRAME 22

Now you know how to find the LMT of Moonrise/set at 0° and 180° longitude. What happens if you are located somewhere in between? You can either divide the Diff. by 180 to find the correction for each "°" or just use the table that's provided. That's right! There is a table provided in the Air Almanac to assist you in interpolating for longitudes other then 0° and 180°. An example of this table, entitled Interpolation of Moonrise, Moonset for Longitudes is reproduced in Figure 19.

Notice that the table actually consists of 3 vertically stacked sections. The top table lists Diff. values from 5-30, the mid level 35-60, and finally values from 65-90. The longitudes are listed along the left side. The 0° longitude value will always be zero and the value at 180° will always be the same as the value at the head of the column.

FRAME 32 (contd)

To obtain the time difference for your location, use the Diff. value you derived from the moonrise/set tables and the longitude value nearest your location the correction amount is accurate enough so that further interpolation is not necessary.

F4 INTERPOLATION OF MOONRISE, MOONSET

FOR LONGITUDE

Add if longitude west
Subtract if longitude east

* When negative subtract correction if longitude west and add if east.

For example, if your Diff. value from the daily pages was 37 and your longitude was 87° West, you would use a Diff. value of 35 and enter the table at 90° longitude to get a correction of + 18 minutes. It is "+" because you're at West Longitude. Select the correction factor from the interpolation table for the following Diff. values and longitudes. When the daily tables indicate a "POSITIVE " Diff. value indicate "+" if the correction is West/ "-" if the correction is East.

EXCEPTION: If the Diff. value in the daily tables is negative "-" then you subtract the correction from the LMT when you are at West longitude and add it if you are East.

	DIFF.	LONG. CORR.
A.	25	100 W.
B.	-7	68 W.
C.	42	122 E.
D.	-16	15 E.

****

ANSWER:

A. +14 C. -27

B. -2 D. +2

Figure 19. Interpolation of Moonrise, Moonset for Longitude.

FRAME 23

To complete the process of obtaining moonrise/set times, use the Conversion of Arc to Time Table from the Almanac (or Figure 5) to convert to LST, at your position, as you did for sun times.
NOTE: Each month there is one day near the first quarter without a moonset and one day near the last quarter without a moonrise. The tabulated times may indicate more than 24 hours (e.g. 24hr 38 min.), or, after conversion, the LST may be over 24 hours (i.e. the next day).

NO RESPONSE NECESSARY

FRAME 24

Using the moonrise and moonset tables for 21 November, shown in pages 31 and 32, the Interpolation for Moonrise, Moonset for Longitude Table (Figure 19), the Conversion of Arc to Time Table (Figure 5), and the conversion tables for Standard time (Air Almanac) find moonrise/set times for the following stations in LST.

			Moonrise/Set
A. Langley AFB, Va	(37° 05' N.	76° 21' W.)	_____/_____
B. Fulda, FRG	(50° 33' N.	9° 41' E.)	_____/_____
C. Osan, Korea	(37° 06' N.	127° 02' E.)	_____/_____

ANSWER:

A. 0724/1655

B. 0818/1601

C. 0709/1657

FRAME 25

Moon phase data are shown at the top of the daily pages in the Almanac. The symbols are related to the phase symbols in Figure 12. At the bottom right of each daily page, the number of days since the last New Moon are given as "Age(#)d." Finally, Fractional Illumination data are also provided in the Air Almanac (see List of Contents).

NO RESPONSE NECESSARY

FRAME 26

For latitudes between 65° and 90° North, Semiduration of Moonlight graphs are provided in the Almanac. These tables are very similar to the Semiduration of Sunlight graphs. Each 'moon' has its own graph.

FRAME 26 (CONTD)

A December 1987 graph is shown in Figure 20. Dates are shown across the bottom and top and meridian passage times are indicated near the top of the chart by dots (.) at one hour intervals. The skewed semiduration lines are similar to those in the sunlight graph, as are the moon above and moon below horizon portions of the graph. Moon phases are indicated on their date of occurrence. Note that the phases correspond to meridian passage times (6 hours apart) and are the same as illustrated in Figure 12. You'll need to keep Figure 12 in mind to ensure the rise/set times are figured for the "correct" day. For example, on 6 December there is a full moon. As depicted in Fig. 12 a full moon passes the meridian near midnight. At 70° North on 6 December, Fig.20 shows that the moon is (continuously) above the horizon. There is, therefore, neither rise nor set on 6 December, but there is continuous moonlight. On 13 December the moon is near third quarter (figs. 12 and 20) and so it passes the meridian near 0600. From Fig. 20, the semiduration of moonlight for latitude 75° North on 13 December is approximately 8 hours. Thus, moonrise is on December 12 at approximately 2200 and moonset on 13 December is approximately at 1400 for latitude 75°.

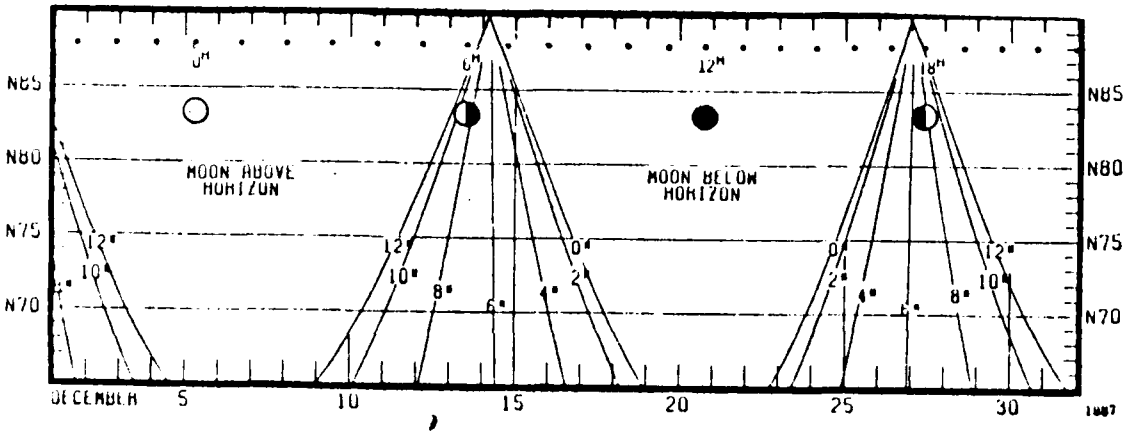

Figure 20. Semiduration of Moonlight

FRAME 26 (CONTD)

Find the LMT of moonrise and moonset for the following dates and latitudes:

	MOONRISE/MOONSET
A. 10 Dec, 74° N.	_____ / _____
B. 25 Dec, 80° N.	_____ / _____
C. 27 Dec, 70° N.	_____ / _____
D. 17 Dec, 69° N.	_____ / _____

****

ANSWER:

A. moon above the horizon.

B. moon below the horizon.

C. 1130, 2330

D. 0559, 1159

TEST QUESTIONS

The following test is provided so you can determine whether or not you reached the objectives stated in the beginning of this Tech Note. Tables and graphs to be used for this test are located on the following pages.

1. State the main reason that sunrise, sunset, and twilight times change from day-to-day.

_____

_____

_____

_____

_____

2. Langley AFB, VA is located at 37° 05' N, 76° 21' N. List the Local Standard Time on 15 April that the following events will occur:

AM Civ Twilight	Sunrise	Sunset	PM Civ Twilight

3. State the Local Mean Time of occurrence at 75° N. on 1 April for the following events:

AM Civ Twilight	Sunrise	Sunset	PM Civ Twilight

4. Name two factors that cause moonrise/set times to change from day to day.

A. _____

B. _____

5. Fulda Gap, FRG is located at 50° 33' N, 9° 41' E. Figure the time of occurrence of the following events on 15 Apr 87.

Moonrise	Moonset
GMT	GMT
LST	LST

6. State the Local Mean Time of moonrise and set at 75° N. on 7 May 87.

Moonrise	Moonset

The above table is for converting expressions in arc to their equivalent in time; its main use in this Almanac is for the conversion of longitude for application to L.M.T. (*added* if *west*, *subtracted* if *east*) to give G.M.T., or vice versa, particularly in the case of sunrise, sunset, etc.

Sunrise/Sunset Calculation Worksheet

I. Obtain Local Mean Time (LMT) from the tables contained in the Air Almanac, pp A130-A145. You will need the date, and the latitude of the location you desire. Some interpolation may be required.

II. Next convert the LMT from Step I to GMT by using the Conversion of Time chart on page A166. The whole degrees (°) of longitude will be converted into hours and minutes using the left column of the chart and the minutes (') of longitude will be converted into minutes and seconds using the right hand column. The times are then added (for West Longitude) to the LMT obtained in step one. The result is the time of the event in GMT.

III. Convert GMT to LST using standard correction obtained from pages A20-A23.

1. Date: _____
2. Latitude: _____
3. Longitude: _____(°) _____(') _____('')
4. Standard Time Correction +/- _____hrs ____min

5. In appropriate page from A130 -A145, At the intersection of items 1 and 2 read the Local Mean Time and enter below:

BEGIN CIVIL TWILIGHT	SUNRISE	SUNSET	End Civil Twilight
_____ LMT	_____LMT	_____LMT	_____LMT

6. From The Arc to Time Table, on page A166: Determine the GMT Conversion_____ hrs_____ min based on whole (°) longitude. Last column_____ min_____ sec based on minutes and seconds of longitude. Combining the two and rounding off seconds to minutes will give you the Total GMT Conversion (7).

7. Total GMT conversion = +/- ___Hrs____Min
(+ correction for West Longitude / - Correction for East Longitude)

8. BEGIN IN GMT-add 5 and 7
(or Civil Twilight)* (5)

	Hrs	Min	
(7) +/-	Hrs	Min	
	Hrs	Min	Z

9. BEGIN IN LST-apply standard cor.(4) to (8) (8)

	Hrs	Min	
(4) +/-	Hrs	Min	
	Hrs	Min	LST

* Civil Twilight can be computed in steps 8 and 9 using data from Civil Twilight tables. NOTE. **Nautical Twilight Time** can be estimated by subtracting the difference between civil twilight time and sunrise from Begin civil Twilight. and adding the difference between civil twilight time and sunset to the end civil twilight time.

MOONRISE/MOONSET CALCULATIONS WORKSHEET

I. Enter the Date, and the latitude/longitude of the location in question on the worksheet below.

II. Using the information from step I determine the Moonrise/set time from the appropriate Air Almanac table (pp 1-732) for the date in question. Some interpolation will be required. This is the Local Mean Time of the event at 0° Longitude. At the same time, copy down the DIFF value from the latitude closest to your location.

III. To convert to local mean time for your location, Enter page F4, using the longitude and the Diff from step II to determine the correction to be applied to LMT. After applying the correction and you will have the local mean time of the event for your location.

IV. Convert to GMT using the procedures below in para 9.

V. Convert to LST using the procdeures in para 10 (The Standard Correction (5) obtained from pages A20-A23 of the Air Almanac.

1. Date: _____
2. Latitude: _____
3. Longitude: _____(°)_____(')_____('')
4. Diff value(s) _____/_____minutes
5. Standard Time Correction _____+/- hrs

6. Using 1 and 2 determine moonrise/set times at 0° Longitude from pp 1-732. MR:_____/MS:_____.

7. Using 3 and 4 determine the correction for your longitude and apply to the time arrived at in 6. MR_____/MS_____.

8. From The Arc to Time Table, on page A166: Determine the GMT Conversion on the left side of the chart _____ hrs_____ min based on whole (°) longitude. From the last column determine the _____min _____sec based on minutes and seconds of longitude. Combining the two and rounding off seconds to minutes will giv you the Total GMT Conversion (8).

9. Total GMT conversion = +/-_____Hrs____Min
(Use a + correction for West Longitude ; a - Correction for East Longitude)

10. MR/MS IN GMT-(add 7 and 9)

	(7)		Hrs	Min
	(9)	+/-	Hrs	Min
			Hrs	Min

11. MR/MS IN LST-apply standard cor. to (10)

	(10)		Hrs	Min
	(5)	+/-	Hrs	Min
			Hrs	Min

PREPARATION OF ASTRONOMICAL DATA - TEST ANSWERS

1. The earth's axis is not perpendicular to the plane of it's orbit. It is tilted 23 1/2°. (or words to that effect.)

2. AM Civ Twilight | Sunrise | Sunset | PM Civ Twilight
   0505 | 0532 | 1840 | 1907

3. AM Civ Twilight | Sunrise | Sunset | PM Civ Twilight
   0304 | 0444 | 1924 | 2104

4. A. The moon's orbital speed
   B. The moon's orbital angle } (in either order)

5. Moonrise | Moonset
   2035 GMT | 0449 GMT
   2135 LST | 0549 LST

6. Moonrise | Moonset
   7 May /0645 | 8 May /0645

If you missed any of these questions, go back and reread the appropriate sections of this Tech Note.
