ABSTRACT

Algorithms for nonlinear programming and variational inequality problems are, in general, only guaranteed to converge in the limit to a Karush-Kuhn-Tucker point, in the case of nonlinear programs, or a solution in the case of variational inequalities. In this paper we derive sufficient conditions for nonlinear programs and variational inequalities such that any convergent algorithm can be modified to guarantee finite convergence to a solution. Our conditions are more general than existing results and, in addition, have wider applicability. Moreover, we note that our sufficient conditions are close to the related necessary conditions, and show by counterexamples that our main nondegeneracy assumptions cannot be relaxed.

Key Words: Convergence of algorithms, nonlinear programs, variational inequalities.

1. Introduction

Numerous algorithms have been devised for the solution of the optimization problem

$$\text{minimize } f(x) \text{ subject to } x \in S. \quad (1.1)$$

Differences in the procedures generally exploit the assumed structure of the objective function f and the feasible set S . In this paper, we develop conditions on f , S , and the solution point under which any infinitely convergent algorithm can be modified to ensure finite convergence. Within the assumptions on f and S we show by counter-examples that the conditions on the solution point are tight. Our results are more general than earlier related results and have been extended to the problem of finding solutions to variational inequalities, which calls for finding a point $x^* \in S$ such that

$$G(x^*)^T (x - x^*) \geq 0 \quad \text{for all } x \in S, \quad (1.2)$$

where G is a continuous mapping from R^n to R^n .

A-1

Problem (1.1) is called a nonlinear program whenever either f is a continuous nonlinear function or the set S is defined by a collection of continuous nonlinear inequalities and equations. Under a suitable constraint qualification (see, e.g., [3]), algorithms for nonlinear programming problems are, in general, only guaranteed to converge in the limit to a Karush-Kuhn-Tucker point (see, e.g., [20]), which may or may not be a local solution. For special cases, convergence to a local solution can be established (e.g., for convex programs [4]), or finite convergence can be assured (e.g., for conjugate direction algorithms applied to bounded quadratic programs using Armijo-type inexact line searches [20]). Algorithms for variational inequality problems typically are guaranteed to converge in the limit to a solution if such a solution is unique. Thus, in most cases, the existing algorithms converge to either Karush-Kuhn-Tucker or solution points in an infinite number of steps. We propose to modify these procedures by imbedding a subproblem (having linear objective function and constraints given by S) that should be solved every fixed number of steps. Under certain conditions, this suffices to guarantee finite convergence to a solution. This idea is reminiscent of the "spacer step" used in nonlinear programming to convert a locally convergent algorithm into a globally convergent one (see, e.g., Huenberger [19]).

Rates of convergence and conditions for finite convergence have been developed by a number of authors for gradient projection algorithms. Bertsekas [5] studied the Goldstein-Levitin-Polyak [10,18] gradient projection method for problem (1.1) with continuously differentiable objective and compact S defined by only upper and lower bounds on the

descent vector (see, e.g., Annals of Math. [2]) the exact line searches. Bertsekas proved that if the sequence generated by the algorithm converges to a local minimum which satisfies strict complementary slackness (SCS) and second order sufficiency conditions (SOSC), then the set of active constraints is identified in a finite number of steps. In [6], Bertsekas develops analogous results for the same problem when applying a projected Newton method. In a related paper, Galim and Bertsekas [15] investigate convergence and rate of convergence of a generalization of the Goldstein-Levitin-Polyak (GLP) method, under the assumptions that f is smooth and real valued and that S is convex in a linear space, to allow different Hilbert norms to be used for the projection operation and the Frechet derivative operation. In a very thorough and rigorous study, Dunn [13] analyzes gradient projection algorithms of the GLP type when applied to a general convex set S in Hilbert space and a continuously differentiable real valued objective function f . When f has a unique minimizer ξ in S , then convergence rates can be obtained and are dependent on how the function

$$\phi(\sigma) = \inf \{f(x) - f(\xi) : x \in S, \|x - \xi\| = \sigma\} \quad (1.3)$$

grows with increasing $\sigma > 0$. Note that the growth of $\phi(\sigma)$ depends on the structure of f , S , and the norm on the Hilbert space. Dunn proves that if, for some $\epsilon > 0$, there exists a scalar $B > 0$ such that $\phi(\sigma) \geq B\sigma^p$ for all $\sigma > 0$, then the process $\{f(x_n)\}$ converges to $\inf \{f(x) : x \in S\}$ linearly, superlinearly, or finitely if $p = 2$, $1 < p < 2$, or $p = 1$, respectively, where $\{x_n\}$ is the sequence of points generated by the GLP

algorithm. The same approach has been successfully used by Dunn to study convergence of other algorithms [10,11,12].

Conditions that use theoretical functions such as (1.3) are useful but difficult to apply. One of the simplest conditions was also provided by Dunn [11] who proved that the gradient projection method identifies the optimal active constraint set in a finite number of iterations whenever SCS holds at the solution. Burke and More [7] extend this result by showing that the optimal active constraints are identified if and only if the projected gradients converge to zero. Finally, Calamai and More [8] generalize the results of Bertsekas [5] by "showing that if the projected gradients converge to zero and if the iterates converge to a nondegenerate point, then the optimal active and binding constraints of a general linearly constrained problem are identified in a finite number of iterations. This result is independent of the method used to generate the iterates and can be applied to other linearly constrained problems." Their proof does not require SOSC and permits S to be a general polyhedral set. By invoking the gradient projection method on selected iterations, Calamai and More were able to develop a finite procedure for determining the global solution of a general quadratic programming problem.

In this paper, we generalize the results of Calamai and More [8] to problems with nonpolyhedral feasible sets and to algorithms which are not based on projected gradient calculations. Moreover, the nature of our approach allows us to extend our results to algorithms for solving variational inequalities. While many of the ideas contained in our results are not surprising, we have not seen them presented elsewhere and

attempt here to structure and characterize general yet useful results for R^n . In addition, our results have much simpler proofs than related results in the literature [5,8,11]. The remainder of this paper is organized as follows. Section 2 is concerned with conditions for finite convergence of algorithms for nonlinear programs with linear constraints. The case of nonlinear programs with nonlinear inequality constraints is dealt with in Section 3, and Section 4 extends the results in the preceding sections to variational inequality problems.

2. NONLINEAR PROGRAMS WITH LINEAR CONSTRAINTS

Consider the linearly constrained nonlinear programming problem of finding a point $x \in R^n$ that will locally

$$\text{minimize } f(x) \quad \text{subject to } Ax = a, \quad Bx \geq b \quad (P)$$

where $f: R^n \rightarrow R^1$ is continuously differentiable, A and B are real $p \times n$ and $m \times n$ matrices, and a and b are real $p \times 1$ and $m \times 1$ vectors, respectively. Let $C = \{x: Ax=a, Bx \geq b\}$ be the feasible set of P .

In general, we seek a local solution to the problem; that is, a point x^* for which there is some neighborhood N (of x^*) such that $f(x) \geq f(x^*)$ for all x in $C \cap N$. If equality holds only for $x = x^*$, then x^* is called a strict local solution of problem P . In contrast, x^* is called an isolated local solution (or a locally unique solution) of problem P if it is the only local solution of P in some neighborhood of x^* . The distinction between strict and isolated local solutions for general, nonlinearly constrained problems has been investigated by Robinson [22] and by Kyparisis and Fiacco [17] who developed sufficient conditions for

each type of solution. As might be expected, the distinction disappears for special cases; e.g., when f is a quadratic function in P (see [14]).

In the sequel, we review several definitions and results from convex analysis and optimization theory which are needed for the development of our conditions. The reader may consult, e.g., Bazaraa and Shetty [3] for complete proofs and further details.

It is well-known [3] that if x^* is a local solution of problem P , then there exists a (dual) vector $(u,v) \in R^{p+m}$ such that (x^*, u, v) satisfies the following Karush-Kuhn-Tucker (KKT) conditions for P

- (i) $\nabla f(x^*) = A^T u + B^T v, \quad v \geq 0,$
- (ii) $Ax^* = a, \quad Bx^* \geq b,$
- (iii) $v^T(Bx^* - b) = 0.$

Denote the index set of binding inequality constraints at x^* by $I^* = \{i: B_i x^* = b_i\}$, where B_i denotes the i th row of matrix B . The corresponding submatrix of $[B, b]$ is denoted by $[B^*, b^*]$. The cone of feasible directions of C at x^* is given by

$$F(x^*) = \{z: z \neq 0, Az = 0, B^* z \geq 0\}$$

and the polar cone of $F(x^*)$ is given by

$$F^*(x^*) = \{y: y = A^T u + B^{*T} v^*, u \in R^p, v^* \geq 0\},$$

where v^* denotes the subvector of v with indices in I^* . Notice that $F^*(x^*)$ is simply the cone spanned by the negative gradients of the

binding constraints at x^* . Now, if x^* is a local solution, then the KKT conditions state that we must have

$$-\nabla f(x^*) \in F^*(x^*), \quad x^* \in C. \quad (2.1)$$

later in this section we utilize the condition that $-\nabla f(x^*)$ is in the interior of $F^*(x^*)$, denoted by $\text{int } F^*(x^*)$. The next proposition states the necessary and sufficient conditions for $\text{int } F^*(x^*)$ to be nonempty.

PROPOSITION 1. The following conditions are equivalent:

- (a) $\text{int } F^*(x^*) \neq \emptyset$
- (b) x^* is an extreme point of C ;
- (c) $\text{rank } [A^I, B^{*I}] = n$; i.e., there are n linearly independent binding constraints at x^* .

One can verify that the interior of $F^*(x^*)$ is given by

$$\text{int } F^*(x^*) = \{-y: y = A^I u + B^{*I} v^*, \text{ where } v^* \geq 0 \text{ is such that } v^{*T} B^{*I} z > 0 \text{ for all } z \in F(x^*)\}.$$

If, in addition, the matrix $[A^I, B^{*I}]$ is $n \times n$, i.e., all the binding constraints are linearly independent (in view of (c) above), then

$$\text{int } F^*(x^*) = \{-y: y = A^I u + B^{*I} v^*, v^* \geq 0\} \quad (2.2)$$

In general, however, $\text{int } F^*(x^*)$ only contains the set $\text{int } F(x^*)$ and the known theorems of the alternative do not seem to be useful in representing $\text{int } F^*(x^*)$ in a simpler form for the general case.

The next result provides several characterizations for the condition $-\nabla f(x^*) \in \text{int } F^*(x^*)$ used in our main theorem.

PROPOSITION 2. Consider the conditions

- (a) $-\nabla f(x^*) \in \text{int } F^*(x^*)$;
- (b) $\nabla f(x^*)^T z > 0$ for all $z \in F(x^*)$ and x^* is an extreme point of C ;
- (c) x^* is the unique solution of $\min\{\nabla f(x^*)^T x \mid x \in C\}$;
- (d) x^* is an isolated local solution of $\min\{f(x) \mid x \in C\}$.

Then, (a) $\Leftrightarrow$ (b) $\Leftrightarrow$ (c) $\Rightarrow$ (d).

Proof. (a) $\Rightarrow$ (b). Condition (a) implies that x^* is an extreme point of C by Proposition 1 and that $\nabla f(x^*)^T z > 0$ for all $z \in F(x^*)$ by definition of $\text{int } F^*(x^*)$.

(b) $\Rightarrow$ (c). Condition (b) implies $\nabla f(x^*)^T (x - x^*) > 0$ for all $x \in C$, $x \neq x^*$, i.e., $\nabla f(x^*)^T x > \nabla f(x^*)^T x^*$ for all $x \in C$, $x \neq x^*$.

(c) $\Rightarrow$ (a). Condition (c) implies $\nabla f(x^*)^T (x - x^*) > 0$ for all $x \in C$, $x \neq x^*$, i.e., $\nabla f(x^*)^T z > 0$ for all $z \in F(x^*)$. By definition of $\text{int } F^*(x^*)$, this means that $-\nabla f(x^*) \in \text{int } F^*(x^*)$.

Finally, (a) implies that the KKT conditions hold at x^* , and (b) implies that $\{z \mid \nabla f(x^*)^T z \leq 0, z \in F(x^*)\} = \emptyset$, so that, by Corollary 1.19 in [14], x^* is an isolated local solution of $\min\{f(x) \mid x \in C\}$ and thus (a), (b), or (c) imply (d).

where $\bar{z} = (z_1, \dots, z_m) \in \mathbb{R}^m$ and $\bar{v} = (v_1, \dots, v_m) \in \mathbb{R}^m$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

Let us assume that $\bar{v} \neq 0$ and $\bar{z} \neq 0$ and $\bar{v} \neq 0$.

$$x^{k+1} = x^k + \frac{1}{2} \|x^* - x^k\| (x^* - x^k)$$

$$\nabla f(x^k) = \nabla f(x^*) + \frac{1}{k} e$$

where $e = (1, 1, \dots, 1)^T \in \mathbb{R}^n$ and $\|\cdot\|$ denotes any norm defined on $\mathbb{R}^n$. If x^* is not an extreme point, it follows that x^* does not solve (2.3) for any finite k . We note that the nondegeneracy assumption of Calamai and More [8] is equivalent to assuming that $F^*(x^*)$ has a nonempty interior and that $-\nabla f(x^*) \in \text{int } F^*(x^*)$.

The preceding theorem suggests that any algorithm which generates a sequence of points converging to an extreme point x^* of a polyhedral set can be modified to guarantee finite convergence, when $-\nabla f(x^*) \in \text{int } F^*(x^*)$, by simply adding the subproblem of solving the linear program (2.3) every, say, n steps. We are guaranteed to reach the threshold k in a finite number of iterations and this is followed by a single linear program to determine x^* .

3. NONLINEAR PROGRAMS WITH NONLINEAR INEQUALITY CONSTRAINTS

Consider the nonlinear programming problem with nonlinear inequality constraints and linear equality constraints

$$\text{minimize } f(x) \text{ subject to } Ax = a, g_i(x) \geq 0, i=1, \dots, m. \quad (\text{NLP})$$

where $f: \mathbb{R}^n \rightarrow \mathbb{R}^1$ and $g_i: \mathbb{R}^n \rightarrow \mathbb{R}^1$ are continuously differentiable, and, for simplicity, it is assumed that all the constraints are binding at x^* .

Let $X = \{x: Ax = a, g_i(x) \geq 0, i=1, \dots, m\}$ be the feasible set of NLP.

It is well known [3] that if x^* is a local solution of problem NLP and an appropriate constraint qualification holds then there exists a vector $(u, v) \in \mathbb{R}^{p+m}$ such that (x^*, u, v) satisfies the following Karush-Kuhn-Tucker (kkt) conditions for NLP:

$$\begin{aligned} \text{(i)} \quad & \nabla f(x^*) + A^T u + \sum_{i=1}^m v_i \nabla g_i(x^*) = 0, \\ \text{(ii)} \quad & A x^* = a, \quad g_i(x^*) \leq 0, \\ \text{(iii)} \quad & v_i g_i(x^*) = 0, \end{aligned}$$

where v_i denotes the Jacobian matrix of the mapping $g = (g_1, g_2, \dots, g_m)^T$.

In our results for this more general nonlinear program, we shall use the cone of p -vectors of X at x^* , denoted by $I(x^*)$, instead of the cone of feasible directions $F(x^*)$. When the constraints are linear, $I(x^*) = F(x^*)$, but in general only $F(x^*) \subset I(x^*)$ holds. The following proposition is well known.

PROPOSITION 3. Assume that the Kuhn-Tucker Constraint Qualification (KTCQ) [3] holds at x^* for NLP. Then,

$$I(x^*) = \{z \in \mathbb{R}^n : z \neq 0, \quad Az = 0, \quad \sum_{i=1}^m v_i \nabla g_i(x^*)^T z \leq 0, \quad i=1, \dots, m\}$$

and the polar cone of $I(x^*)$ is given by

$$I^*(x^*) = \{v \in \mathbb{R}^m : v = A^T u + \sum_{i=1}^m v_i \nabla g_i(x^*)^T, \quad u \in \mathbb{R}^p, \quad v_i \geq 0\}$$

Of course, a number of other constraint qualifications which imply KTCQ can be used; for example, the Linear Independence CQ or, in the case of convex constraints, g_i , the Slater CQ (see [3]). Note also that if x^* is a local solution and KTCQ holds, then the kkt conditions imply that

$$-\nabla f(x^*) \in L^*(x^*), \quad x^* \in X. \quad (3.1)$$

PROPOSITION 4. Assume that the KTCQ holds at x^* . Then, the following conditions are equivalent:

- (a) $\text{int } L^*(x^*) \neq \emptyset$;
- (b) $\text{rank } [A^T, \nabla g(x^*)^T] = n$; i.e., there are n linearly independent binding constraints at x^* .

The formula for $\text{int } L^*(x^*)$ is identical to that for $\text{int } F^*(x^*)$ with $\nabla g(x^*)$ substituted for B^* . Therefore, the discussion in Section 2 of various representations of $\text{int } F^*(x^*)$ applies here to $L^*(x^*)$.

The following lemma characterizes the key condition $-\nabla f(x^*) \in \text{int } L^*(x^*)$ that will be used later.

PROPOSITION 5. Assume that the KTCQ holds at x^* and consider the following conditions:

- (a) $-\nabla f(x^*) \in \text{int } L^*(x^*)$;
- (b) $\nabla f(x^*)^T z > 0$ for all $z \in T(x^*)$;
- (c) x^* is the unique solution of $\min\{\nabla f(x^*)^T x : x \in X\}$;
- (d) x^* is an isolated local solution of $\min\{f(x) : x \in X\}$.

Then, (a) $\Leftrightarrow$ (b) $\Rightarrow$ (c) and (d).

Proof (a) $\Leftrightarrow$ (b). Follows from the definition of $\text{int } L^*(x^*)$.

(b) $\Rightarrow$ (c). Condition (b) implies $\nabla f(x^*)^T (x - x^*) > 0$ for all $x \in x^* + L(x^*)$, which in turn implies (c) since $X \subset x^* + L(x^*)$.

(a) $\Rightarrow$ (d). Condition (a) implies that the KKT conditions hold at x^* and

that $\{z: \nabla f(x^*)^T z \leq 0, z \in I(x^*)\} = \emptyset$, so that, by Corollary 4.10 in [17], x^* is an isolated local solution of $\min\{f(x): x \in X\}$.

The main result of this section parallels Theorem 1 and gives conditions under which an infinitely convergent algorithm for NLP can be modified to converge in a finite number of steps.

THEOREM 2. Assume that f and g are continuously differentiable and that the KTCQ holds at $x^* \in X$. Suppose that $\{x^k\} \subset X$, $x^k \rightarrow x^*$, and $\text{rank}[A^T, \nabla g(x^*)^T] = n$. If $-\nabla f(x^*) \in \text{int } T^*(x^*)$, then there is a positive integer K such that, for all $k > K$, x^* uniquely solves the nonlinear program

$$\text{minimize } \nabla f(x^k)^T x \text{ subject to } x \in X. \quad (3.2)$$

Conversely, if x^* solves (3.2) for all k larger than some number K , then x^* is a Karush-Kuhn-Tucker point of problem NLP.

Proof: By the continuous differentiability of f , we have $-\nabla f(x^k) \in \text{int } T^*(x^*)$ for sufficiently large k , since $x^k \rightarrow x^*$ and $-\nabla f(x^*) \in \text{int } T^*(x^*)$. Thus, $\nabla f(x^k)^T z > 0$ for all $z \in I(x^*)$; i.e., $\nabla f(x^k)^T (x - x^*) > 0$ for all $x \in x^* + I(x^*)$. Since $X \subset x^* + I(x^*)$, then $\nabla f(x^k)^T x > \nabla f(x^k)^T x^*$ for all $x \in X$, $x \neq x^*$. The converse follows immediately from continuous differentiability of f .

Remark. Analogous to Theorem 1, in the above theorem, we cannot relax the assumption that there are n linearly independent binding constraints at x^* , even if we require $-\nabla f(x^*)$ to be only in the relative interior of $T^*(x^*)$.

Theorem 2 suggests that any algorithm for NLP which generates a sequence of points converging to a point x^* can be modified to guarantee finite convergence, when $-\nabla f(x^*) \in \text{int } T^*(x^*)$, by adding the nonlinear program (3.2) with linear objective function every, say, n steps. This is guaranteed to yield a local solution x^* in a finite number of iterations.

4. EXTENSIONS TO VARIATIONAL INEQUALITIES

In this section we consider the variational inequality problem of finding a point $x^* \in S$ such that

$$G(x^*)^T (x - x^*) \geq 0 \quad \text{for all } x \in S, \quad (\text{VI})$$

where $G: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is continuous, S is a convex feasible set and x^* is called a solution of VI. Note that x^* solves the following convex program

$$\text{minimize } G(x^*)^T x \quad \text{subject to } x \in S. \quad (\text{CP})$$

Furthermore, x^* is called an isolated solution (or a locally unique solution) of problem VI if it is the only solution of VI in some neighborhood of x^* .

Problem VI is, in a sense, a generalization of the nonlinear program NLP (and also of P). For example, if x^* is a local solution of NLP and if feasible set X in NLP is convex, then x^* solves VI with $G(x) = \nabla f(x)$ and $S = X$. Indeed, if the objective function f and set X in NLP are

convex, then VI subsumes NLP as the special case where $G(x) = \nabla f(x)$. On the other hand, problem VI directly generalizes the nonlinear (and therefore also linear) complementarity problem, which is obtained by setting $S = \{x \mid x \geq 0\}$. Algorithms for variational inequalities in most cases converge in the limit to a solution of VI if such a solution is unique (see Pang and Chan [21] and Dafermos [9]). Thus, finite convergence of these algorithms is also of interest in the VI case.

The results from Sections 2 and 3 directly extend in most cases to problem VI with an appropriate feasible set. Consider problem VI with a polyhedral feasible set $S \subset \mathbb{C}$ (as defined in Section 2). Then CP becomes a linear program with optimal solution x^* . Thus, there exists a vector $(u, v) \in \mathbb{R}^{p+m}$ such that (x^*, u, v) satisfies the following generalized Karush-Kuhn-Tucker (GKKT) conditions for VI.

$$\begin{aligned} \text{(i)} \quad & G(x^*) = A^T u + B^T v, \quad v \geq 0, \\ \text{(ii)} \quad & Ax^* = a, \quad Bx^* \leq b, \\ \text{(iii)} \quad & v^T (Bx^* - b) = 0. \end{aligned}$$

The cones $F(x^*)$ and $F^*(x^*)$ are defined exactly as in Section 2, and Proposition 1 and comments following it apply without any changes. The GKKT conditions may be expressed in the form

$$G(x^*) \in F^*(x^*), \quad x^* \in C \quad (1.1)$$

A strengthened condition $G(x^*) \in \text{int } F^*(x^*)$ is characterized in the next result.

PROPOSITION 6. Consider the conditions:

- (a) $-G(x^*) \in \text{int } F^*(x^*)$;
- (b) $-G(x^*)^T z > 0$ for all $z \in F(x^*)$ and x^* is an extreme point of C ;
- (c) x^* is the unique solution of $\min\{G(x)^T x : x \in C\}$;
- (d) x^* is an isolated solution of $G(x)^T (z - x) \geq 0$ for all $z \in C$.

Then, (a) $\Leftrightarrow$ (b) $\Leftrightarrow$ (c) $\supset$ (d).

Proof. The first three equivalencies are proved exactly as in

Proposition 2. The last implication follows from Theorem 2.3 in John [23] since the GKL conditions hold at x^* and since $\{z : G(x^*)^T z = 0, z \in F(x^*)\} = \emptyset$.

The conditions under which an infinitely convergent algorithm can be modified to converge in a finite number of steps are stated in the theorem below whose proof is analogous to the proof of Theorem 1 in Section 2 and is omitted.

THEOREM 7. Assume that G is continuous and suppose that $\{x^k\} \subset C$, $x^k \rightarrow x^*$ and x^* is an extreme point of C . If $-G(x^*) \in \text{int } F^*(x^*)$ then there is a positive integer K such that for all $k \geq K$, x^* uniquely solves the linear program

$$\text{minimize } -G(x^k)^T x \quad \text{subject to } x \in C. \quad (1.7)$$

Conversely, if x^* solves (1.7) for all k larger than some number K then x^* is a generalized Karush-Kuhn-Tucker point of problem VI.

follows. As in Theorem 1, the assumption that x^* is an extreme point of C can be relaxed, even if we require $G(x^*)$ to be in the relative interior of $L^+(x^*)$.

Theorem 3 shows that any algorithm for VI with a polyhedral feasible set $S \subset C$ which generates a sequence of points converging to an extreme point x^* of C can be modified to guarantee finite convergence, provided that $G(x^*) \in \text{int } L^+(x^*)$. This is accomplished by solving an additional linear program (1.4) every ϵ (say 10) steps (see also the comments following Theorem 1).

Consider now problem VI with a convex feasible set $S \subset X$, as defined in Section 3 with the additional assumption that each g_i is concave. For simplicity, we assume that all the constraints are binding at x^* . Thus, if the constraint qualification KQ holds at x^* (see Section 3), then there exists a vector $(u, v) \in R^{p+m}$ such that (x^*, u, v) satisfies the following generalized Karush-Kuhn-Tucker (GKKT) conditions for VI:

$$\begin{aligned} \text{(i)} \quad & G(x^*) - \sum_{i=1}^p u_i G_i(x^*) - \sum_{j=1}^m v_j G_j(x^*) = 0, \\ \text{(ii)} \quad & Ax^* - a_i - G_i(x^*) = 0, \\ \text{(iii)} \quad & \sum_{j=1}^m v_j G_j(x^*) = 0. \end{aligned}$$

The definitions of cones $L(x^*)$ and $L^+(x^*)$ given in Section 3 as well as Propositions 3 and 4 and the comments following them in the same section apply without any changes. Also, the GKKT conditions may be expressed in the form

$$G(x^*) \in L^+(x^*), \quad x^* \in X \quad (1.3)$$

The next result characterizes the key assumption in the subsequent main theorem, namely the condition $-G(x^*) \in \text{int } L^*(x^*)$. Its proof is similar to the proofs of Propositions 5 and 6.

PROPOSITION 4. Assume that the KQC holds at x^* and consider the following conditions:

- (a) $-G(x^*) \in \text{int } L^*(x^*)$;
- (b) $G(x^*)^T z > 0$ for all $z \in L(x^*)$;
- (c) x^* is the unique solution of $\min\{G(x^*)^T x : x \in X\}$;
- (d) x^* is an isolated solution of $G(x)^T(z - x) \geq 0$ for all $z \in X$.

Then, (a) $\Leftrightarrow$ (b) $\Rightarrow$ (c) and (d).

The conditions under which an infinitely convergent algorithm can be modified to converge in a finite number of steps are given below. The proof of this result is analogous to the proofs of Theorems 2 and 3. Observe also that since $G(x^*)^T x$ is linear and X is convex, in view of Proposition 4, part (c), x^* must be an extreme point of X . Recall that this was the case for problem VI with polyhedral feasible set C (see Theorem 3).

THEOREM 4. Assume that G is continuous, g is concave and that the KQC holds at x^* . Suppose that $\{x^k\} \subset X$, $x^k \rightarrow x^*$, and $\text{rank } [A^T, \nabla g(x^*)^T] = n$. If $-G(x^*) \in \text{int } L^*(x^*)$, then there is a positive integer K such that, for all $k \geq K$, x^* uniquely solves the convex program

$$\text{minimize } G(x^k)^T x \quad \text{subject to } x \in X \quad (4.4)$$

conversely, if x^* solves (4.4) for all k larger than some number k_0 , then x^* is a generalized Karush-Kuhn-Tucker point of problem IV.

Remark. As in Theorem 2, we cannot relax the assumption that there are n linearly independent binding constraints at x^* , even if we require $-G(x^*)$ to be only in the relative interior of $L^*(x^*)$.

Theorem 4 shows that any algorithm for VI with a convex set X which generates a sequence of points converging to x^* can be modified to guarantee finite convergence, when $-G(x^*) \in \text{int } L^*(x^*)$, by solving an additional convex program (4.4) with linear objective function every, say, n steps.

5. Concluding Remarks

We have derived necessary conditions and sufficient conditions under which any convergent algorithm for certain nonlinear programming problems and variational inequality problems can be modified to ensure finite convergence. Throughout we assumed the objective function to be continuously differentiable and considered generalizations of the constraints to extend our results. Using our approach, it appears that the most general constraints we can assume are linear equality and nonlinear inequality satisfying a constraint qualification. Moreover, we cannot relax the nondegeneracy assumptions on the solution points (namely, the polar cones are full dimensional and contain the negative gradients in their interior) and still ensure finiteness. In this sense, our results cannot be further weakened without additional assumptions.

Some existing algorithms may immediately benefit from results contained in this paper. For example, when the Al Khayyal and Falk [2]

algorithm is applied to problems having global solutions that are nondegenerate extreme points, then the procedure is finite without modification. This is because the algorithm incorporates a step which solves a subproblem analogous to problem (2.3) before branching. Further refinements of the procedure and a specialized proof of finite convergence for nondegenerate linear complementarity problems have been investigated by Al-khayyal [1].
