ABSTRACT

The theory, detailed outline of operating and algorithm procedures of a continuous time-invariant, linear control state variable systems design and analysis computer program is presented. The program, SVS, which is based on Melsa's LINCON, was modified to demonstrate Controllability, Observability, Bode Plot, Root locus plot, Nyquist plot, pole placement, Luenberger observer design, optimal control design, time response plot and some basic matrix manipulations. Worked examples with the program output are included. Some options give only numeric data output; others give both numeric data and high-resolution graphs. The software, which is fully interactive, menu driven and user friendly is written in Turbo Pascal to be run on the IBM-PC microcomputers. All options are presented via option menus and the user will be prompted for all input parameters.

LIST OF FIGURES

I. LINEAR CONTROL STATE VARIABLE SYSTEMS (SVS)

A. INTRODUCTION TO THE SVS

SVS is software for the IBM-PC microcomputer in the analysis and design of continuous time, linear control systems. These programs are based on the matrix mathematics of state variables and were first developed by Melsa [Ref. 1] and adapted for batch use at NPS by Desjardins [Ref. 2].

The original intent of this thesis was simply to take Desjardins' adapted version of Melsa's LINCON and modify it for the Turbo Pascal computer language. The features of this thesis are:

- User-friendly as possible
- Menu-driven program. <Q>quit key always returns to the SVS main menu.

The hierarchical menu structure is three levels deep at any point. So the user, before selecting his/her option, can get help at every menu.

SVS was tested with several examples and is now available to any user on the Naval PostGraduate School control laboratory PC's under the SVS directory name.

B. SYSTEM REQUIREMENTS

SVS is a large program and requires at least 512KB of Memory to run. The program will run on any IBM-PC or compatible "MS-DOS" computer and requires a standard IBM color Graphics Adapter (CGA) or IBM Enhanced Graphics Adapter (EGA) card. It will run on either monochrome or color monitor, but all menus are supported by color, for that reason they are easier to work with a color monitor if available. The graphics in the program are in high resolution (640 X 200) mode. They only appear in the white-on-black. The graphics can be dumped to an EPSON, IBM-Graphics, or compatible printer by using the Shift + PrtSc key.

The program is written in the Turbo Pascal Language. Turbo Pascal has a 64K data segment and code sizes limitation. Under this restriction, SVS is compiled as five executable programs and nineteen "Chain" files. The main program name is SVS in the disk files. It has extension .COM. The chain files have extension .CHN and they are not themselves executable.

C. FILES ON THE DISK

A complete list of the files and a brief description of these are below.

```
(1) SVS.COM      { The executable main menu module }
(2) INPUT.COM    { The input/change menu module }
(3) MATRIX.COM   { The matrix mathematics menu module}
(4) PLOT.COM     { The graphics menu module }
(5) CHANGE.CHN   { Allows user to change input data
                 { values}
(6) POLYNOM.CHN  { Calculates characteristic
                 { polynomial of A matrix  }
(7) CONTROL.CHN  { Calculates controllability of the
                 { system  }
(8)DETERMIN.CHN  { Calculates determinant of the A
                 { matrix }
(9) EIGEN.CHN    { Shows eigenvalues of the A matrix }
(10)BODE.CHN     { Gives Bode plot of the system }
(11)TIMEPLOT.CHN{ Gives time response of the system}
(12)OBSER.CHN    { Calculates observability of the
                 { system}
(13)LUENBERG.CHN{ Design Luenberger observer to
                 { achieve a closed-loop poles of the
                 { system  }
(14)OPTIMAL.CHN  { Optimal control design program  }
```

```
(15)POLE.COM       { To calculate feedback coefficients
                   { to achieve a desired closed-loop
                   { poles  }
(16)SAVE.CHN       { Saves data to desired drive  }
(17)RETRIEVE.CHN   { Gets data from desired drive  }
(18)INVERSE.CHN    { To calculate inverse of the A
                   { matrix  }
(19)INPUTDAT.CHN   { To permit user to enter the input
                   { data for whole system  }
(20)HELP1.CHN      { Help program for SVS main menu
                   { options}
(21)HELP2.CHN      { Help information for the
                   { input/change menu options  }
(22)HELP3.CHN      { Help information for the matrix
                   { mathematics menu option  }
(23)HELP4.CHN      { Help information for graphics menu
                   { option  }
(24)NYQUIST.CHN    { to calculate Nyquist (polar) plot
                   { of the system }
(25)RLOCI.CHN      { Root locus plotting procedure}
(26)ROOTS.CHN      { Shows plant characteristic
                   { equation roots }
```

In addition to these files, there are three "system" files that are needed to run the program. These are 4X6.FON, 8X8.FON and ERROR.MSG files.

D. STARTING TO THE SVS

This software package has two diskettes. The first step is to get the SVS main menu on your screen. All you have to do is follow these steps:

1. Turn on the power (or, if it's already on, the user reboots the computer).

2. Wait for the operating system prompt. It will look like one of the following:

   C:_

   C>_

   C\>_

   C:_

   C:\>_

   <C\>_

   (or some other letter).

   The prompt may look somewhat different, depending on the computer and how it has been set up.

3. Type **MD SVS** and press **<ENTER>** key. This opens a new directory.
4. Type **CD\SVS** and press **<ENTER>** key. This enters the new directory.
5. Insert disk #1 into disk driver A:

   Type **Copy A:*.*** and press **<ENTER>** key.
6. Repeat step 5 for disk #2.
7. Type **SVS** and press **<ENTER>** key.

Now the user is in the SVS main menu and ready to work. Make a choice for further step.

II. INPUT/CHANGE MENU

A. INTRODUCTION TO THE INPUT/CHANGE MENU

The first step, of course, is to enter the A, B and C matrices into the computer as a common input. This is the starting point of the program. For our case, the general state variable equations are represented by the following equations.

$$\dot{x}(t) = A\,x(t) + B\,u(t) \qquad (2\text{-}1)$$
$$y(t) = C\,x(t) + D\,u(t) \qquad (2\text{-}2)$$

where A, B, C are given matrices and D is assumed to have a zero elements for this program.

Figure 2.1 The SVS main menu.

From the opening menu of SVS, shown in Figure 2.1, we choose the "Input/Change Plant Matrices Menu" option to bring us to the Input/Change menu shown in Figure 2.2.

```
*** INPUT / CHANGE MENU ***
    (I) Input Plant Matrices
    (C) Change Current Plant Matrices

    (S) Save Plant Matrices to Disk File
    (L) Load Plant Matrices From Disk File

    (H) Help
    (Q) Quit to SVS Main Menu

Make Your Selection
```

Figure 2.2 The input/change menu.

This input/change menu allows the user to enter common inputs to all programs. These common inputs are the plant or A matrix, the input or B matrix and the output or C matrix. The only restriction is the dimensions of the matrix. It must be no greater than 10. This means that the maximum matrix size has to be 10X10. However, due to a user decision, a dimension size not to exceed 6 is required. The reasoning behind this was due, in part, to the printer. Since the output format to the printer is E11, this naturally limits us to 6 numbers per line. I2 format places are normally considered necessary for good accuracy. For systems with order greater than 6, every row of the matrix is continued on the second line. After attempting this, it was decided the results were difficult to read. Otherwise it is appropriate up to a 10^{th} order system.

B. INPUT PLANT MATRICES

This option is used to initially enter the A, B and C matrices of the state variable equations (2-1) and (2-2). For this option, select the "Input plant matrices" from the input/change menu. The screen will prompt the degree of the plant, which is the dimension of the A matrix. The maximum acceptable degree is 10. Then it asks for elements of the A matrix and so forth.

Matrices are entered one element at a time beginning with 1,1 and continuing across the row of the matrix. The next row is then entered, and the process continues until all elements have been entered. After the matrix is entered, the complete matrix is automatically brought to the screen for review and possible element changes. If a change to the matrix is desired the user simply enters the row and column number to change after every prompt. Then the program asks for corresponding matrix elements to change. After being prompted, the change is entered. A review of the matrix is again brought to the screen. The user is again prompted for any more possible changes. This procedure continues until all changes have been done. The same A matrix procedures are repeated for the B and C matrices. This input data can be used for the options without saving to disk file until quitting the program.

C. CHANGE CURRENT PLANT MATRICES

This option allows the user to change input data A, B and C matrices quickly and easily. The user can change the order and elements of the matrices that were previously entered. This powerful combination facilitates both input correction and changes, especially for higher order matrices during the design process. First Figure 2.3 appears on the screen. The user can choose one matrix at a time for correction. Then the program gives the order and elements of the selected matrix. In the beginning the user can enter a

```

  ==================================================

  Which matrix do you want to change ?  PLANT (A) A_
                                        INPUT (B)
                                       OUTPUT (C)

  Press <ESC> to change it!,
  Then input your choice with <ENTER> key
```

Figure 2.3 Change current plant matrices selection.

correction to the order of the matrix. Then, under the new dimension, can make corrections on elements of the matrix. The program shows the corrected results on the screen. At the end of the program, the user automatically returns to the input/change menu. If the user wants to change more than one matrix, he/she must choose the "Change Current Plant Matrices" option two or more times. A basic example for this option is illustrated in Figure 2.4.

D. SAVE CURRENT MATRICES TO DISK FILE

This procedure is used to store plant matrices to the hard disk or floppy disk file. First it prompts drive C as a saving drive. Then asks the user for the drive designator (A through E), and filename for the problem to be saved. Eight characters of a MS-DOS filename are allowed; the program gives a filename extension of ".SVS" to each data. This extension is used to limit the disk search for appropriate files. A drive and filename are supplied by the program, which opens the file and stores the data. The procedure stores the data as a text file. A text file consists of ASCII characters, and is usually designed to hold readable information [Ref. 3].

E. LOAD PLANT MATRICES FROM DISK FILE

The procedure first asks the data drive where the problems are stored. After this is done, the program calls another procedure called "Directory" [Ref. 4]. This procedure uses MS-DOS function, calls and shows all available data files on the screen. The user can choose one of the files by moving arrow keys with <RETURN> key. Then the program opens the file and reads it.

The directory displays only the disk files with the extension ".SVS". This eliminates the possibility to read other files.

```
The A matrix is :

```

Figure 2.4 Change current plant matrices example.

III. GRAPHICS MENU

A. INTRODUCTION TO THE GRAPHICS MENU

From the opening menu of SVS, shown in Figure 2.1, we choose the " Graphics Menu " option to bring us the Graphics menu shown in Figure 3.1. The Graphics menu contains five basic options. These are the time response plot, Nyquist plot, Root locus plot, characteristic equation roots and Bode plot. This menu is also supported with the "Load plant matrices from disk file" option. This selection allows the user to get data from the disk file quickly instead of going via the SVS main menu route.

```
*** GRAPHICS MENU ***

      (L) Load Plant Matrices From disk File

      (C) Characteristic Equation Roots
      (B) Bode Plot
      (N) Nyquist Plot
      (T) Time Response Plot
      (R) Root Locus Plot

      (H) Help
      (Q) Quit to SVS Main Menu

  Make Your Selection
```

Figure 3.1 The graphics menu.

B. BODE PLOT

Bode plot analysis can be accomplished with the Graphics menu by selecting the <B> Bode plot option. This selection brings Figure 3.2 to the screen. There are two selections for the frequency plot: the open-loop Bode plot and closed-loop Bode plot. Input data for this option is entered with the Input/change plant matrices menu selection which is explained in Chapter II. If the user wants the closed-loop Bode plot, the program automatically calculates for the negative unity-feedback condition.

```
           *** Bode Plotting Parameters ***
       ========================================

Open (O) or Closed (C) Loop Plot?                        O

What is the first frequency to be plotted?  .1
 (Example: .01, 1, 100, etc. )

How many decades do you want plotted?                    4
```

Figure 3.2 Bode plot parameters selection.

The user also must enter the starting frequency and number of decades for the plotting. The upper frequency limit is calculated based on the number of decades. That is, if user selects .1 as the starting frequency with 4 decades, then the upper frequency will be 1000 rad/sec.

Bode plot displays two plots at the same time. These are plots of magnitude and phase versus radian frequency. Magnitude is converted to the decibels unit using the relation

$$\text{Magnitude}_{dB} = 20 \log_{10}(\text{magnitude})$$

and phase is converted to degrees using the relation

$$\text{Phase}_{degree} = (180/\pi)\ \text{Phase}$$

Magnitude calculations for the single pole or zero can be written as

$$\text{Magnitude} = [\text{Realpart}^2 + (\text{w-Imaginarypart})^2]^{1/2}$$

and the phase calculation is

$$\text{Phase} = \text{Tan}^{-1}[(\text{w-Imaginarypart})/\text{Realpart}].$$

For the whole system, the magnitude and phase are calculated for each pole or zero. Then the final magnitude is

$$\text{Magnitude}_{system} = \text{Magnitude}_{zeros}/\text{Magnitude}_{poles}$$

and the phase is

$$\text{Phase}_{system} = \text{Phase}_{zeros} - \text{Phase}_{poles}$$

The plots of the magnitude and phase are shown on the same graph. Coordinate values of 0dB magnitude and -180° phase coincide in the graph. We know from control theory that phase margin is read at the zero crossover of the magnitude curve and the gain margin is read at the -180° crossover of the phase curve. These two values can be read directly from the graph. The Bode routine calculates the numbers required for the plots. The procedure "plot-Bode" converts the number to a graphical display. Within the Bode-plot routine is a call to the procedure "graph-menu". Graph-menu is called by all procedures which produce a graph. It provides a small menu offering the user the choice to add a title to the graph, print the graph on the printer, print the number or quit and return to the menu.

If the user selects the title to graph and it is completed, the plot is displayed with the title on the screen. The title block can be moved by using the cursor arrow keys and relocated anywhere on the screen. When the title box is moved where the user wants, the <enter> key must be pressed. Then the screen is frozen in position and the graph menu is recalled on the screen.

The print numbers selection saves the current graphic screen and permits the user to print the numbers used to draw the graph. The numbers may be printed on the printer (this will use a lot of paper) or to a disk file. If the disk option is selected, the user can scan that file with a word processor or by using the DOS "type" command and examine the points of interest. This option is illustrated on example 3.1.

EXAMPLE 3.1

The example can be stated as follows: Given plant transfer function

$$Gp(s)= \frac{100\ (\ 0.02\ S + 1)}{(s + 1)\ (\ .1\ s + 1)\ (.01\ s + 1)^2} \qquad (3\text{-}1)$$

was rearranged as a state variable equations.

$$\dot{x}(t)= \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -100000 & -112000 & -12210 & -211 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} u(t)$$

$$y(t) = \begin{bmatrix} 10000000 & 200000 & 0 & 0 \end{bmatrix} x(t)$$

a) Obtain the Bode diagram of the above system.

b) Mark the following on the Bode diagram, recording the numerical values.

1) Gain crossover frequency
2) Phase margin
3) Phase crossover frequency
4) Gain margin
5) Resonant frequency.

Solution:

Given data entered to the program by the selecting of the "Input Plant Matrices" option in the input/Change menu. Then the program outputs can be seen from the Figure 3.3 and Figure 3.4.

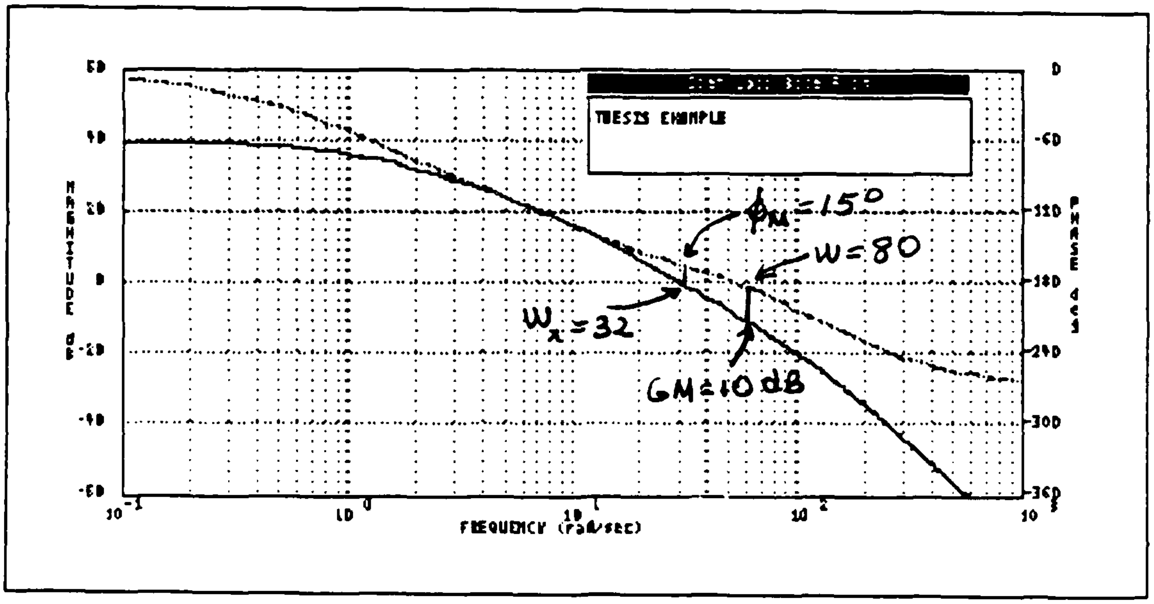

Figure 3.3 Open loop Bode plot for example 3.1.

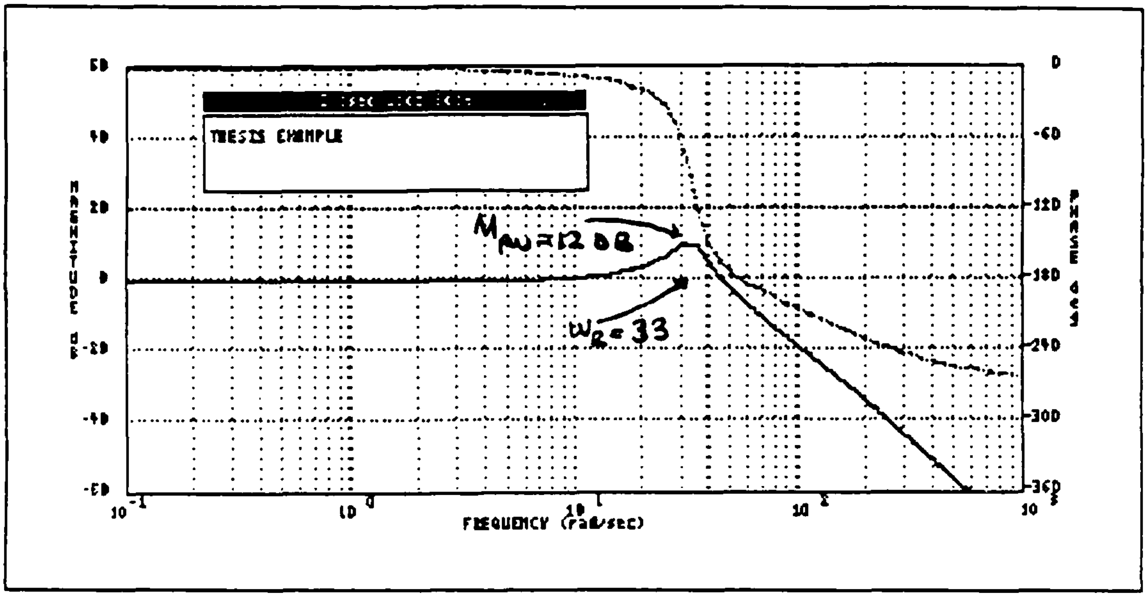

Figure 3.4 Closed loop Bode plot for example 3.1.

C. TIME RESPONSE PLOT

It is desirable to see the system's response in the time-domain to a typical input. Time response can be calculated and plotted with the SVS program as can the system input sinusoid, ramp, step or impulse. All these inputs have user selectable amplitudes. Figure 3.5 shows the time response parameter screen.

The time response algorithm first converts the A, B and C matrices to the open loop transfer function, then into a discrete-time, state-space equivalent. The theory of the time response plot is not included here. Users who want more information about the subject should consult reference 4, or any other relevant textbooks.

EXAMPLE 3.2

For the given system in example 3.1, obtain the time response plot and mark the following on the time response plot, recording the numerical values.

1) Settling time

2) Maximum overshoot for a step input.

Solution:

The program data has already entered for the Bode plot. The selecting "Time response Plot" in the graphics menu gives figure 3.6 as a problem solution.

```
      *** Time Response Plotting Parameters ***
 =================================================

What is your input to the system? STEP (S)   S
                                  RAMP (R)
                             SINE WAVE (W)
                               IMPULSE (I)

What is your input amplitude?   1

Input one of these choices, Open (O) or Closed (C) C

Input your simulation time to the system (99max) 1.4
```

Figure 3.5 Time response parameters screen.

D. NYQUIST PLOT

This section presents the Nyquist plot option. This selection gives open loop and unity-feedback closed loop Nyquist plot. The program first calculates open loop transfer function of the plant. Then the plot is obtained by calculating the magnitudes and phases angle of the transfer function for a specified

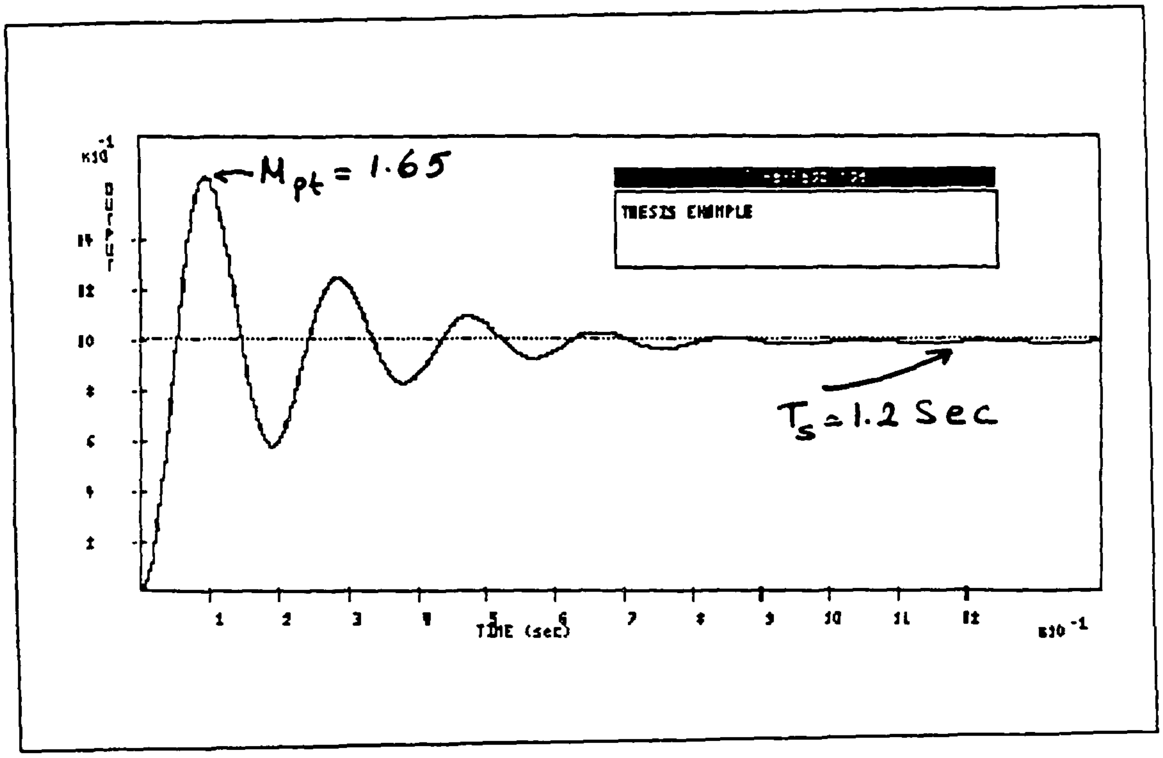

Figure 3.6 Time response plot for example 3.2.

number of times with a specified increment of w. Before proceeding to the Nyquist plot, the program prompts the menu of Figure 3.7. This parameters screen allows the user to enter additional data for the plotting. The graphic window size is given 100X100 scale if the user selects the big picture option. The select own size option asks the user to enter starting frequency, number of decades and X,Y coordinates maximum and minimum values for the plot. After getting the plot, the procedures are the same as with the Bode plot option. These are make a title to the graph, printer output and listing numbers (which are used to generate a graph) either to the printer or a specified file with a given drive name.

***** Nyquist Plotting Parameters *****

Open (O) or (C) Closed loop plot?   O

Input your first frequency to be plotted?   .1
(Example: .01, 1, 100, etc.)

Input number of decades do you want plotted?   4

X-Maximum   100

X-Minimum   -100

Y-Maximum   100

Y-Minimum   -100

Any changes to these parameters? (Y / N)   N

Press <F1> to change previous entry

Figure 3.7 Parameters selection for the Nyquist plot.

EXAMPLE 3.3

Figure 3.8 shows the Nyquist plot for the example 3.1 A, B and C matrices.

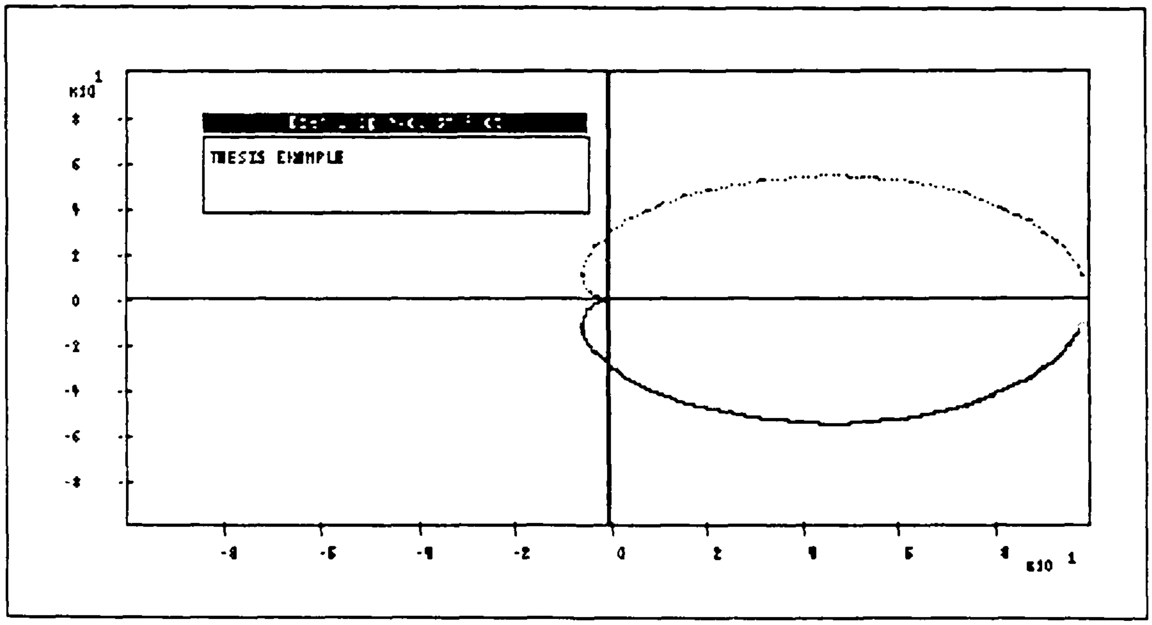

Figure 3.8 Example of the Nyquist plot.

E. ROOT LOCUS PLOT

This option plots the loci of the closed loop poles of a system with transfer function $G(s) = K\,N(s)/D(s)$ for varying gain. N(s) and D(s) are polynomials of the plant and the program calculates from the given A, B and C matrices.

The user is prompted to enter the starting and ending gain values, maximum and minimum X,Y coordinate values and to select either positive or negative feedback. These plotting parameters are shown on Figure 3.9. After this input routine, the program assumes unity feedback and calculates root locations for varying gain and plots them.

```
*** Root Locus Plotting Parameters ***

Input STARTING value for the varying gain    0
Input ENDING value for the varying gain      10

      X-Minimum     -100
      X-Maximum      100
      Y-Minimum     -100
      Y-Maximum      100
Positive or Negative feedback? ( P / N )     N
Any changes to these parameters?    N
```

Figure 3.9 Parameters screen for the root locus.

EXAMPLE 3.4

Figure 3.10 shows the Root locus plot for the given data on the example 3.1.

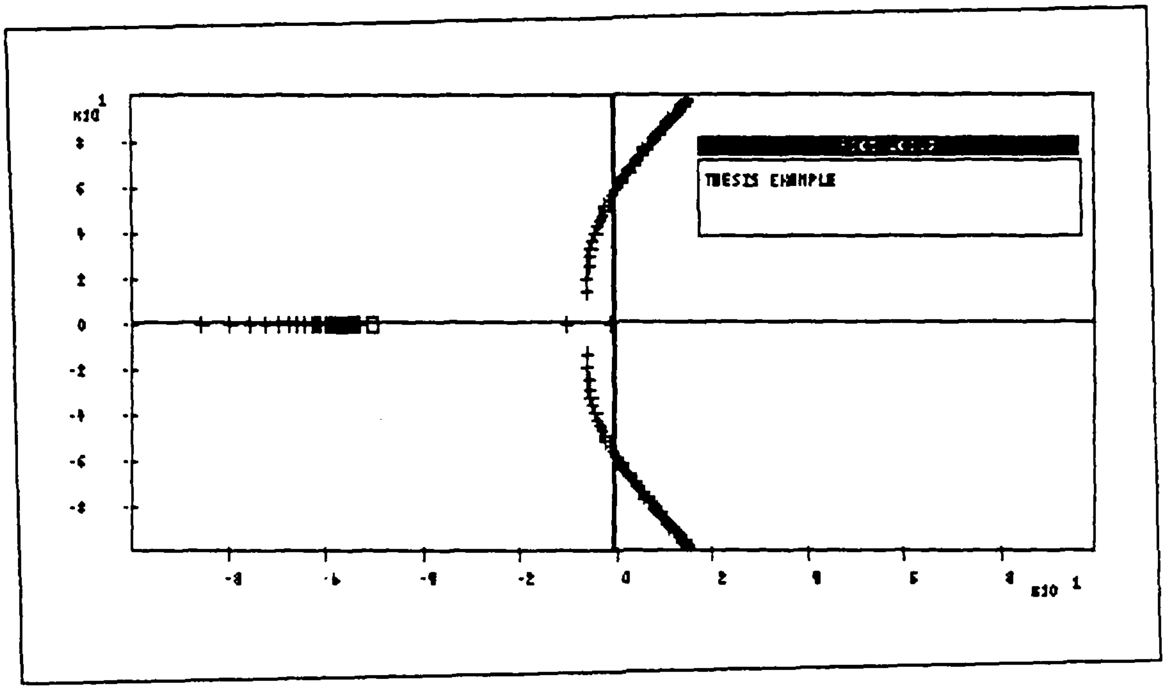

Figure 3.10 Example for the root locus plot.

F. CHARACTERISTIC EQUATION ROOTS

This option of the graphics menu allows the user to decide whether the system is stable or unstable by looking at the root location of the characteristic equation. The program gives again the unity-feedback closed loop characteristic equation roots of the plant. The illustrative program output of the example 3.1 can be seen in Figure 3.11.

G. LOAD PLANT MATRICES FROM DISK FILE

This last option of the graphics menu allows the user to get saved data from disk file directly instead of going via to the main menu and input/change menu.

IV. SVS MAIN MENU

A. INTRODUCTION TO THE SVS MAIN MENU

In this chapter six options are presented which may be used for the analysis and design of control systems. These options are supported by the other options which are explained in Chapter II and III.

The observability option is used to determine the observability index of the system. Another very similar program, controllability is used to determine the controllability of the system. The matrix mathematics option brings to the screen another menu selections. This program calculates an A matrix determinant, inverse, characteristic polynomial and eigenvalues. The last three options may be used to design optimal linear control systems. The pole placement option is useful in the design of linear control state variable feedback control systems. In the pole placement case, the control is computed by multiplying by a gain [K], the difference between the reference input and a weighted (linear) sum of the state variables. The Luenberger observer design is used to design a combined observer-controller to achieve a given desired closed loop transfer function when some of the states are not accessible.

Design of optimal control will minimize a given cost function which produces a scalar control. The program starts to work at the terminal time and works backwards in time.

B. CONTROLLABILITY

This option is used to determine the controllability of the linear time-invariant system. Consider the following continuous-time system

$$\dot{x}(t) = A\,x(t) + B\,u(t) \tag{4-1}$$

where

x = state vector

A = plant matrix

B = input matrix

u = control input

The system described by the above equation is said to be state controllable at a given initial time if it is possible to construct an unconstrained control signal which will transfer an initial state to any final state in a finite time interval [Ref. 5].

This requires an algebraic condition such that the rank r(C) of the controllability condition matrix

$$C = [B \mid AB \mid \ldots\ldots \mid A^{n-1}B] \tag{4-2}$$

is n, the order of the system.

EXAMPLE 4.1

Consider the matrices A and B,

$$A = \begin{bmatrix} 0 & 1 & -1 \\ 1 & 0 & 1 \\ 0 & 1 & -1 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix}$$

Determine if [A, B] is a controllable pair.

<u>Solution</u>: Since A is 3x3 and B is 3x2, matrix C has to be 3x6. The program checked the rank of the controllability condition matrix. The result of the

program can be seen in Figure 4.1, the system is controllable.

```
                    CONTROLLABILITY    RESULT
The Plant matrix A is :
  Ø.ØØØØØE+ØØ   1.ØØØØØE+ØØ   -1.ØØØØE+ØØ
  1.ØØØØØE+ØØ   Ø.ØØØØØE+ØØ   1.ØØØØØE+ØØ
  Ø.ØØØØØE+ØØ   1.ØØØØØE+ØØ   -1.ØØØØE+ØØ

The input Matrix B is :
  1.ØØØØØE+ØØ   Ø.ØØØØØE+ØØ
  Ø.ØØØØØE+ØØ   1.ØØØØØE+ØØ
  Ø.ØØØØØE+ØØ   Ø.ØØØØØE+ØØ

The system is controllable.
```

Figure 4.1 Controllability program output.

C. OBSERVABILITY

In this section we determine observability index of the linear systems. Consider the unforced system described by the following equations:

The (unforced) time invariant system

$$\dot{x} = Ax \qquad (4\text{-}3)$$

with the observation vector

$$y = Cx \qquad (4\text{-}4)$$

The observability index, which is defined as the rank r(O) of the observability condition matrix

$$O = \begin{bmatrix} C \\ CA \\ \cdot \\ \cdot \\ CA^{n-1} \end{bmatrix} \qquad (4\text{-}5)$$

is n, the order of the system.

The program output for this selection is illustrated in Figure 4.2 with the A matrix as given on example 4.1 and the following C matrix.

$$C = [\, 1 \quad 0 \quad 0 \,] \tag{4-6}$$

```
                 OBSERVABILITY RESULT

The Plant matrix A is :

  0.00000E+00  1.00000E+00  -1.0000E+00
  1.00000E+00  0.00000E+00   1.00000E+00
  0.00000E+00  1.00000E+00  -1.0000E+00

The Output Matrix C is :

  1.00000E+00  0.00000E+00   0.00000E+00

The system is observable with index 3.
```

Figure 4.2 Observability program output.

D. POLE PLACEMENT

Any single-input single-output linear, time invariant system is described by the following equations:

$$\dot{x}(t) = A\, x(t) + B\, u(t) \tag{4-7}$$

$$y(t) = C\, x(t) \tag{4-8}$$

The plant is characterized as a block diagram in Figure 4.3.

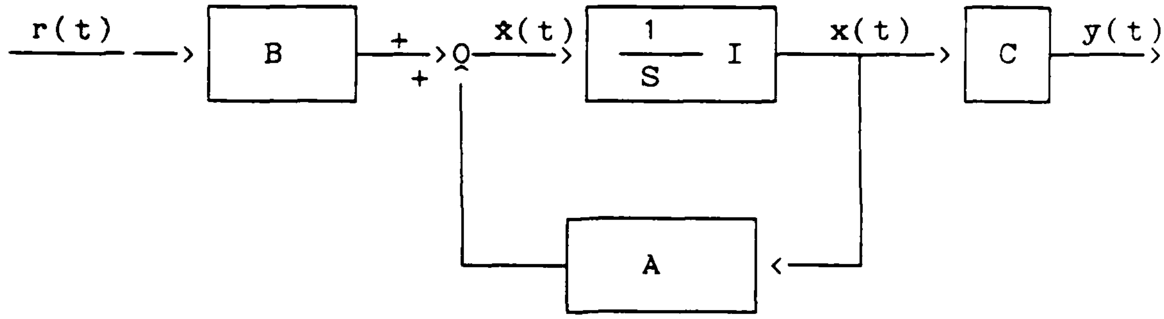

Figure 4.3 Block diagram for the state variable representation.

The closed loop nature of the system of Figure 4.4 is showed by the presence of the controller. It generates the control signal u from the knowledge of the state variables. So, we can see that, except for the reference input [r], the state of the plant x is the only information needed by the controller. The

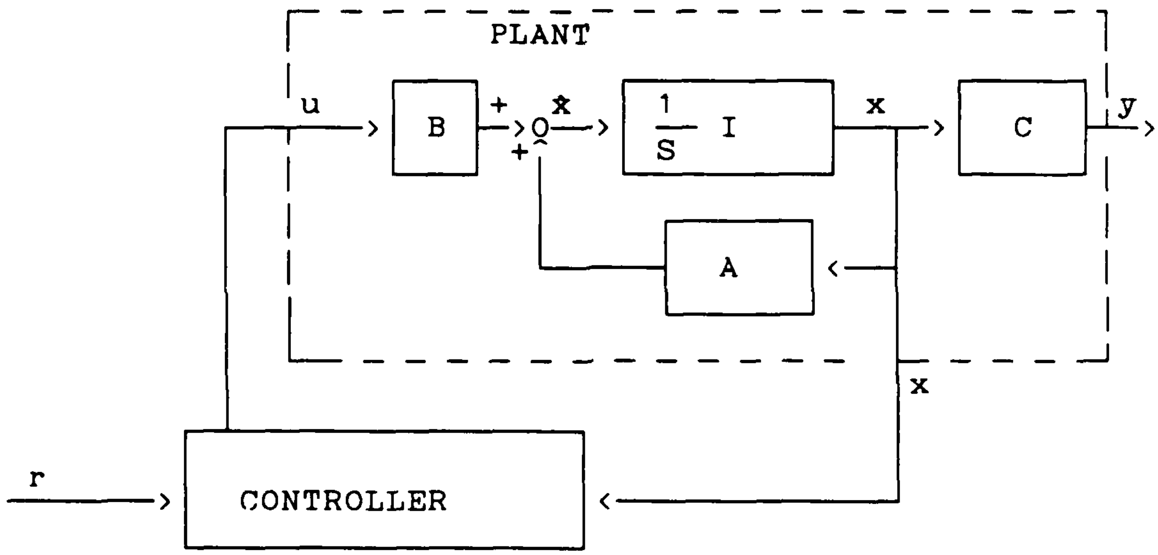

Figure 4.4 General closed loop system with state variable feedback.

control input is computed by the multiplying by a gain K the difference between the reference input and a weighted (linear) sum of the state variables. As a mathematical expression,

$$u = K\ [\ r - (\ k_1x_1 + k_2x_2 + \ldots + k_nx_n\ )] \qquad (4\text{-}9)$$

where the k_i's are referred to as feedback coefficients. The gain K is referred to as the controller gain. The equation (4-9) may be simplified by making it in the matrix notation

$$u = K\ [\ r - k^T\ x\ ] \qquad (4\text{-}10)$$

After all this notation, the graphical representation of the system configuration is shown in Figure 4.5.

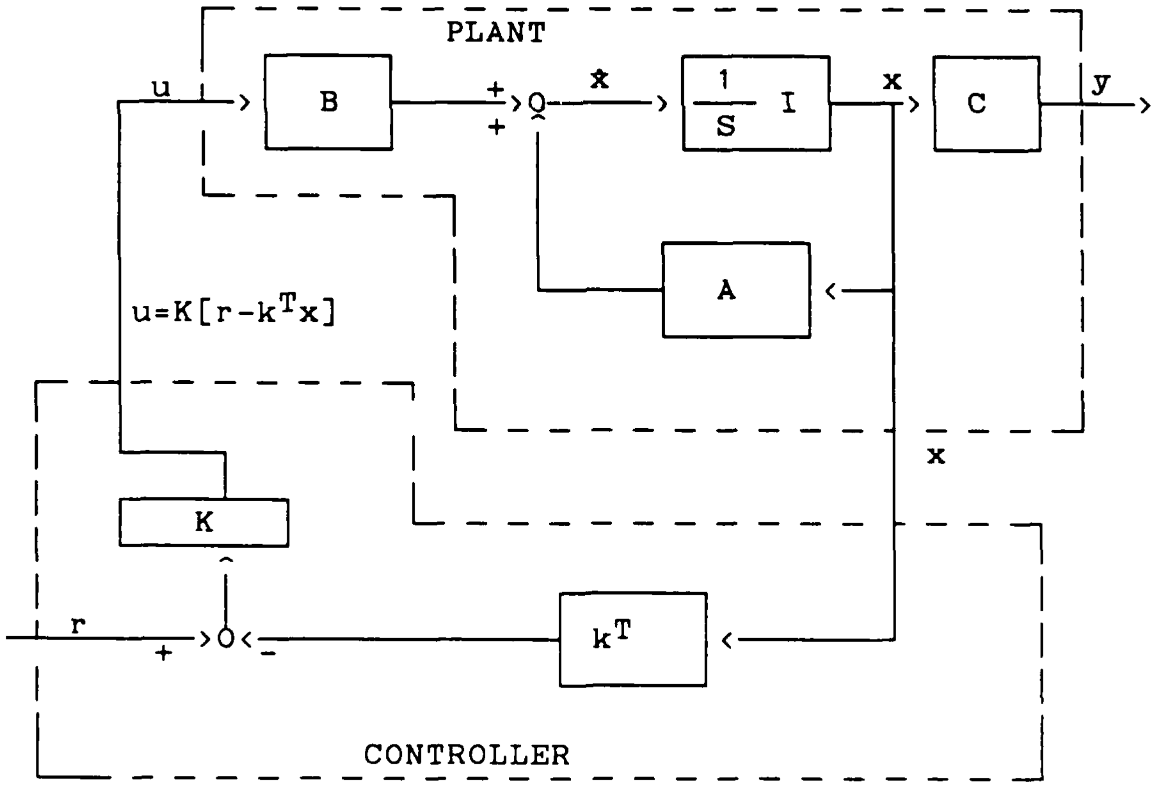

Figure 4.5 Linear state variable feedback system.

We could obtain the closed loop transfer function Y(s)/R(s) from the state variables. Our approach is to force the system into the configuration shown in Figure 4.6.

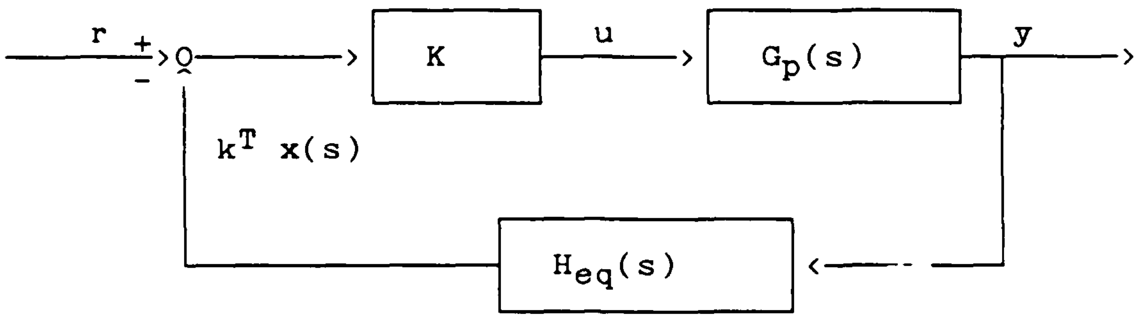

Figure 4.6 Closed loop block diagram representation.

We can see that $H_{eq}(s)$ is given by

$$H_{eq}(s) = \frac{k^T\ x(s)}{y(s)} \qquad (4\text{-}11)$$

Since $y(s) = C\ x(s)$, this expression becomes

$$H_{eq}(s) = \frac{k^T\ x(s)}{C\ x(s)} \qquad (4\text{-}12)$$

Here it must be pointed out that the program calculates the gain K, so zero steady state error results from a step input. If the user wants other conditions, he may rescale K and k^T appropriately by hand. For example, assume he wants to desire to have the controller gain, $K=K_1$, but the program output shows that $K=K_\emptyset$ with the feedback coefficients k_1, k_2, k_3. The procedure is then to modify the program outputs by setting $K=K_1$ and setting

$$k^T = \frac{K_\emptyset}{K_1} [\ k_1\ k_2\ k_3\ ] \qquad (4\text{-}13)$$

This procedure does not change Y(s)/R(s) and satisfies the condition $K=K_1$. Under these notations and block diagrams, this option gives an open loop transfer function Y(s)/U(s) for the plant, the feedback transfer function Heq(s), the controller gain [K] and the feedback coefficients $[k^T]$ to achieve the desired closed loop characteristic polynomial.

The desired closed loop characteristic polynomial is the denominator of Y(s)/R(s) and must agree with the order of the plant. The user can enter this polynomial either in coefficient form or factored form. If the user wants to enter the coefficient form, the coefficient of the highest degree term must be unity.

The methodology for computing the result is: the coefficients of the denominator polynomial of Y(S)/R(s), which is the polynomial desired by the user, may be adjusted at will by proper selection of k and K. The closed loop zeros are equal to the open loop zeros. In other words, linear state variable feedback has no effect on the zeros of Y(s)/R(s). The program calculates the numerator of Heq(s) to achieve the desired characteristic polynomial. Note that the complete Heq(s) is calculated by taking the numerator of Heq(s) and dividing it by the numerator of Y(s)/U(s). In the program procedures, the coefficients of the characteristic polynomial are computed by the use of the Principle-Minor method. For the matrix inverse calculation, the program uses the diagonalization procedures.

EXAMPLE 4.1

The plant matrices of a third order system are given in the following state variable representation:

$$\dot{x}(t) = \begin{bmatrix} -1.0 & 1.0 & 0.0 \\ 0.0 & 0.0 & 1.0 \\ 0.0 & -3.0 & 0.0 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} u(t) \quad (4\text{-}14)$$

$$y(t) = [\ 1.0 \quad 1.0 \quad 0.0\ ]\ x(t) \quad (4\text{-}15)$$

Find the feedforward (controller) gain [K] and the feedback coefficients $[k^T]$ required to achieve a closed loop transfer function of

$$\frac{Y(s)}{R(s)} = \frac{2\ (s + 2)}{s^3 + 4s^2 + 6s + 4} \quad (4\text{-}16)$$

The program result for this example is presented in Figure 4.7.

```

   0.5000   0.0000   1.5000
The gain [K] is :  2.0000
```

Figure 4.7 Program output for the pole placement (continued)

The results shown in Figure 4.7 specify that the gain of the controller [K] is 2.0 and the feedback coefficients are k_1=0.5, k_2=0.0 and k_3=1.5.

E. LUENBERGER OBSERVER DESIGN

Consider a linear time invariant plant of the form

$$\dot{x}(t) = A\,x(t) + B\,u(t) \tag{4-17}$$

$$y(t) = C\,x(t) \tag{4-18}$$

Let a feedback control law for equations (4-17) and (4-18) will be

$$u(t) = K\,[\,r(t) - k^T x(t)] \tag{4-19}$$

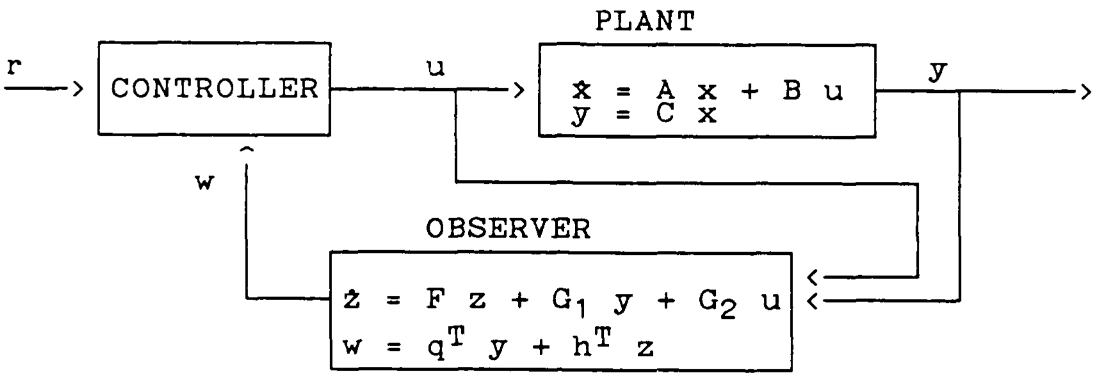

Figure 4.8 Luenberger observer block diagram.

Assume without loss of generality that the plant is controllable and observable. Since the state of equation (4-17) is not directly available to implement equation (4-19), an observer of the form

$$\dot{z}(t) = F\,z(t) + G_1\,y(t) + G_2\,u(t) \tag{4-20}$$

and replacing the true states with estimates yields

$$u(t) = K\,[\,r(t) - k^T z(t)] \tag{4-21}$$

$$k^T z(t) = h^T z(t) + q^T y(t) \tag{4-22}$$

will be designed. The resulting closed loop system is shown in Figure 4.8.

Where

x = state vector

u = control input

y = output

r = system forcing input

$\dot{z}$ = estimated state vector

A = plant matrix

B = input matrix

F = observer eigenvalues matrix

G_1 and G_2 = observer gain matrices

K = controller gain

q^T = output feedback coefficients matrix

h^T = observer feedback coefficients matrix

```

Press <ESC> to change it!,
Then type your input with <ENTER> key
```

Figure 4.9 Luenberger observer design parameters.

The user has to enter the controller gain and the feedback coefficients which can be found by the use of "pole placement" option. The program asks the observer eigenvalues which are represented by the F matrix in the program. The observer degree depends on the observability index. For example, if the observability index r is the minimum integer, then the observer gain matrix [G] has order r. Simply the order of the observer, when the program prompted can be entered, As equal to or greater than (r-1). These input parameters are shown in Figure 4.9.

EXAMPLE 4.2

The example presented here for the fourth degree plant is taken from Desjardin's [Ref. 2]. The plant is represented by the following equations.

$$y(t) = [\ 10 \quad 20 \quad 0 \quad 0\ ]\ x(t) \tag{4-23}$$

$$\dot{x}(t) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & -15 & -23 & -9 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} u(t) \tag{4-24}$$

Solution:

<u>Step1</u>

The x_1 and x_2 are the only measurable states and we want to achieve following closed loop transfer function.

$$\frac{Y(s)}{R(s)} = \frac{1}{s^4 + 6s^3 + 17s^2 + 28s + 20} \tag{4-25}$$

The controller gain [K] and the feedback coefficients required are found, as can be seen from Figure 4.10 by the use of the "Pole placement" option in the same menu. Results shown in Figure 4.10 indicates that the feedback coefficients [k^T] are -3, -6, 13, 20 and the controller gain [K] equals unity.

```

```

Figure 4.13 The Luenberger observer design output.

example, we want to design observer eigenvalues of -3.5 and -4.0.

Step5

The program results for all this input data is shown in Figure 4.13. From results, the complete system can be described as:

$$\dot{x}(t) = \begin{bmatrix} 0.0 & 1.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 1.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 1.0 \\ 0.0 & -15. & -23. & -9. \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_2(t) \\ x_3(t) \\ x_4(t) \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} u(t)$$

$$\dot{z}(t) = \begin{bmatrix} -7.5 & -1.0 \\ -14. & 0.0 \end{bmatrix} \begin{bmatrix} z_3(t) \\ z_4(t) \end{bmatrix} + \begin{bmatrix} 85.5 & 29.25 \\ 0.0 & 0.0 \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix}$$

$$+ \begin{bmatrix} -3.0 \\ -1.5 \end{bmatrix} u(t)$$

$$u(t) = 1.0\, r(t) - [\,20.0 \quad 8.5\,] \begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix}$$

$$- [1.0 \quad .0] \begin{bmatrix} z_3(t) \\ z_4(t) \end{bmatrix}$$

F. DESIGN OF OPTIMAL CONTROL

The system considered is described by the following state variable equation:

$$\dot{x}(t) = A\, x(t) + B\, u(t) \qquad (4\text{-}26)$$

where

x = state vector

u = control input

A = plant matrix

B = input matrix

The design of optimal control will minimize the following cost function:

$$J(N) = 1/2[\ XT(N)\ Q\ X(N) + \sum_{k=0}^{N-1}[X(k)\ Q\ X(k) + R\ U^2(k)] \qquad (4\text{-}27)$$

where the following are defined

Q = noise covariance matrix
N = time intervals over which the SUM is made
R = scalar random input
and XT means transpose of X.

The physical interpretation of J(N) is this: we wish to keep the state near zero without excessive control energy expenditure. The input parameters of the design of optimal control are entered in the beginning of the program. This screen can be seen in Figure 4.14. After entering these parameters and the Q matrix, then the program calculates the feedback gain matrix which, when multiplied by the state vector, yields a scalar control. In the program procedures, the following equations were derived using dynamic programming, starting at the terminal time and working backwards.

P(k)=PSIT(k) * P(k-1) * PSI(k) + Q + GT(k) * R * G(k), P(Ø)=Ø (4-28)
PSI(k)=FI + GAMMA * GT(k), PSI(Ø) = Ø (4-29)
GT(k)=-[GAMMAT * P(k-1) * FI]/[GAMMAT * P(k-1) * GAMMA + R], GT(Ø)=Ø (4-30)

*** **Design of optimal control procedure** ***

Input number of time intervals for SUM procedure? 40

What is your sample interval? 0.1

What is the value of scalar R? 2.0

For the following options which cost function do you want? 0

COST=terminal+fuel+trajectory or

COST=terminal+trajectory <0>

COST=terminal+fuel or COST=terminal <1>

where

$$\text{terminal} = 1/2\ XT(N)\ Q\ X(N)$$

$$\text{trajectory} = 1/2 \sum_{k=0}^{N-1} X(k)\ Q\ X(k)$$

$$\text{fuel} = 1/2 \sum_{k=0}^{N-1} R\ U^2(k)$$

Press <ESC> to change it!,

Then type your input with <ENTER> key

Figure 4.14 Optimal control parameters screen.

For simplicity in programming, the following definitions are defined:

$$\text{Terminal} = 1/2\ XT(N) * Q * X(N) \tag{4-31}$$

$$\text{Trajectory} = 1/2 \sum_{k=0}^{N-1} X(k) * Q * X(k) \tag{4-32}$$

$$\text{Fuel} = 1/2 \sum_{k=0}^{N-1} R * U^2(k) \tag{4-33}$$

EXAMPLE 4.3

Given the system equation and parameters described below find the discrete steady state gains for a sample interval 0.1, scalar R is 1.0 and number of time intervals is 40.

$$\dot{x}(t)=\begin{bmatrix} 0 & 1 \\ 5 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(t) \qquad (4\text{-}34)$$

The graphic result of the program is shown in Figure 4.15 and Figure 4.16, the numerical output is in the Figure 4.17.

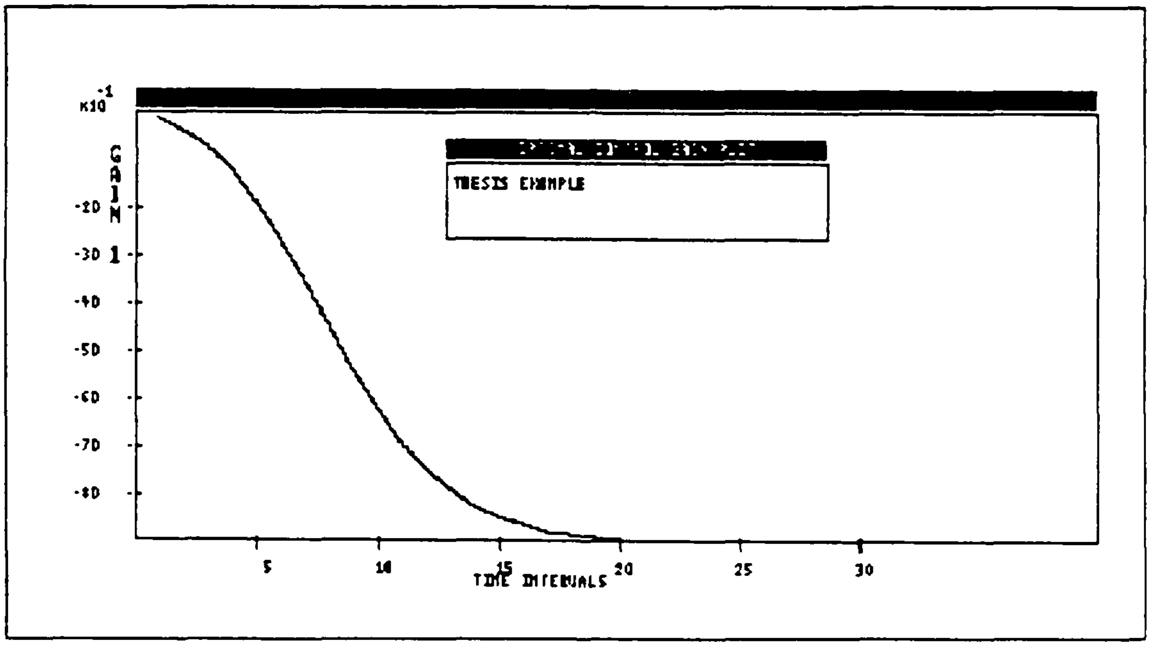

Figure 4.15 Optimal control graphic output #1.

G. MATRIX MATHEMATICS MENU

This option is used to get various calculations with the plant matrix A of a given linear control state variable system. The selection from the SVS main menu brings the matrix mathematics menu. This second menu consist of following options:

(1) The determinant of A matrix

(2) The inverse of A matrix

(3) The characteristic polynomial of A matrix

(4) The Eigenvalues of A matrix

Before selecting this option, the user must select "Input/Change Plant Matrices" option to enter the plant matrices.

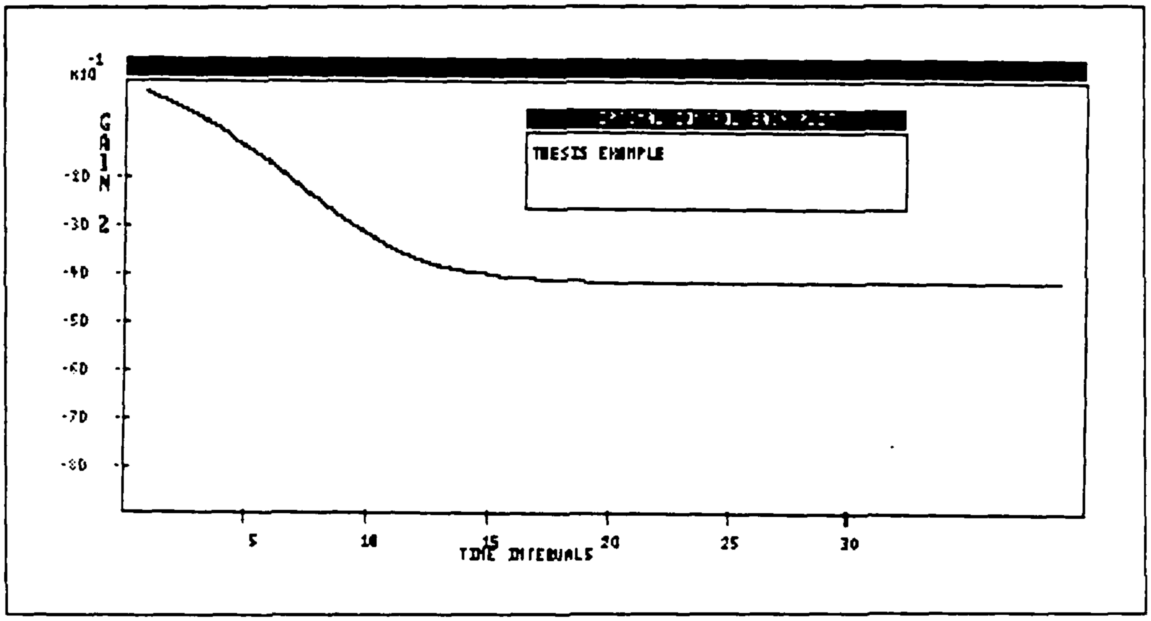

Figure 4.16 Optimal control graphic output #2.

OPTIMAL CONTROL RESULT

The order of the system is : 2
The number of time intervals is :1.0E-01
The scalar R is : 1.0000
The sample interval is : 40

The A matrix is:

0.00000E+00	1.00000E+00
5.00000E+00	0.00000E+00

The B matrix is:

0.00000E+00
1.00000E+00

The Q matrix is:

1.00000E+00	0.00000E+00
0.00000E+00	2.00000E+00

The FI matrix is:

1.02510E+00	1.00835E-01
5.04177E-01	1.02510E+00

The GAMMA matrix is:

5.02087E-03
1.00835E-01

MINIMIZATION OVER ALL STAGES

(stages)	GT:2	GT:2

V. CONCLUSION AND RECOMMENDATIONS

The software, SVS, is written as a teaching learning tool for student use. It can be a nice tool for analysis and design of linear control state variable systems. The program is fully interactive and menu driven. The user does not get lost in the program. The <Q> key always returns to the main menu or CTRL + C key interrupts the program. All options were tested solving several example problems. Hopefully, all "bugs" have been eliminated.

Furthermore, the program can still be easily improved and expanded. These are listed below.

(1) Adding the ability to handle the KALMAN filtering.

(2) Add the capability of the program to handle discrete time systems.

APPENDIX A

UTILITI FILES

A set of Turbo Pascal input and menuing utilities was used widely in the program. These are public domain utilities and was copied from the LCS-CAD source diskettes. These utilities, called TURBO-UT.PAS were written by:

Donald R. Ramsey
Larry Romero
727 Bunker Hill #70
Houston, Texas 77029

and distributed through the public domain. The describing documentation are presented on reference 4.

APPENDIX B

PROGRAM LISTING

Appendix B is a listing files of the Turbo Pascal source code. These files make up the major modules of the SVS program. In general, most of the driver programs and including files are listed in the following pages. The source modules from the Borland International Turbo Graphix Toolbox and the input/output utility routines are not listed.

```
Program State Variable System(input,output);
(* ********************************************* *)
(* The following include files contain procedures  *)
(* to handle graphics call from the main procedures*)
(* of this program. These include files are a part *)
(* of Borland International's Turbo Graphix Toolbox*)
(* Which is a commercially available product.      *)
(* ********************************************* *)
